LINEAR DIFFERENTIAL EQUATIONS.

Theory of Differential Equations. By A. R. Forsyth, Sc.D., LL.D., F.R.S. Part iii. Ordinary Linear Equations. Vol. iv. Pp. xvi + 534. (Cambridge: The University Press, 1902.)

IN this volume Prof. Forsyth deals with a part of his subject which, for many reasons, is full of interest. Ordinary linear differential equations concern the physicist, on the one hand, by their occurrence in the analysis required for many of his most important problems; on the other, they offer the pure mathematician an attractive field of research which appears to be almost inexhaustible.

Thanks to the contributions of a host of analysts, the theory of linear equations has now reached a high stage of development, and, as in other like cases, it is extremely interesting to see how different parts of it, which at first seemed isolated, are being gradually brought into organic connection. One of the first great steps in this direction was made by Gauss in his memoir on the hypergeometric series; this is another example of the extraordinary and almost uncanny way in which Gauss transformed and generalised every subject that he touched. It is as if his predecessors had been hewing stones for him to fit together into the lower courses of a stately building which he left for others to complete. And worthy successors have not been wanting, of whom, perhaps, Riemann is as yet the chief. For his brief memoir on the P-function marks an epoch by introducing several new notions of the very highest importance—the indices associated with the critical points, the analytical continuation of a branch of the function which satisfies the equation and the group of linear substitutions generated by describing cycles including critical points.

The real significance of Riemann's paper became fully evident only after the appearance of the celebrated memoir of Fuchs. It is, of course, impossible to say how Fuchs arrived at his discoveries; very likely he could not have explained his induction completely himself. In the introduction he refers to Briot and Bouquet as well as to Riemann, and acknowledges his obligations to Weierstrass. Fuchs deals with an equation of quite general order, the coefficients being functions of x with a limited number of singularities. He shows that in the neighbourhood of each critical point a there is a solution of the form $(x-a)^k\phi$, where ϕ is a one-valued analytical function and k is a constant determined by an equation which can be constructed from the differential equation itself. He also shows how the simplest independent solutions group themselves according to the multiplicities of the roots of the indicial equation.

The importance of these expansions near the critical points is that, besides giving us information about the analytical properties of the function defined by the differential equation, they enable us to investigate the group of substitutions associated with it. Suppose, for instance, we have an equation of the second order, and that in the neighbourhood of a there are two solutions of the form $(x-a)^h\phi$ and $(x-a)^k\psi$; if the independent variable starts near a and describes a small circuit round it, the solutions, by continuous variation, are multiplied by $e^{2\pi hi}$ and $e^{2\pi ki}$ respectively; thus with these solutions we have a substitution of the form $y'_1 = sy_1$, $y'_2 = ty_2$, where s, t are constants. When the indicial equation for a has multiple roots, the associated substitution is less simple, but can always be determined. If we start from *any* ordinary point with a set of independent solutions, then by Weierstrass's principle of continuation we can (in theory at least) follow up their values as x approaches a critical point a, then find the substitution which takes place as x goes round a, and finally bring back x to its original position. The effect of any closed circuit can thus be determined; and we have, on the whole, a group of linear substitutions, with generators corresponding to the critical points.

The singularities of an integral are determined by the coefficients of the differential equation; they may be poles or they may be essential singularities. One of the most remarkable things in Fuchs's paper is the determination of the form which a differential equation must have if all its integrals are regular in the neighbourhood

of each critical point; that is to say, if near any critical point a each integral can be put into the form

$$y = (x-a)^k \left\{ \phi_0 + \phi_1 \log(x-a) + \ldots + \phi_m [\log(x-a)]^m \right\}$$

where $\phi_0, \phi_1, \ldots \phi_m$ are one-valued functions not infinite at a. These equations are called by Prof. Forsyth "equations of Fuchsian type." The equation of the hypergeometric series is of this type, and is remarkable as being the only one, of order higher than the first, which is completely determined when the positions of the critical points and the indices associated with them are assigned.

An equation of Fuchsian type may have one or more algebraic integrals. If all the integrals are algebraic, the group of the equation must be finite; so here we have a most unexpected concurrence of two apparently disconnected theories. A very interesting problem is that of determining linear equations the groups of which are isomorphic with known finite groups; another is that of finding out whether a given equation has any algebraic integrals.

All the foregoing theory is discussed and illustrated by Prof. Forsyth in a very attractive and lucid manner; thus chapter i. deals with the existence of a synectic ntegral near an ordinary point and sets of independent integrals; chapter ii. with the expansions near a critical point and with Hamburger's method of grouping them; chapter iii. with regular integrals; chapter iv. with equations of Fuchsian type; and chapter v. with equations of the second and third orders possessing algebraic integrals. Illustrations are supplied by the familiar equations of mathematical physics, by the equation of the elliptic quarter-period, and by that of the hypergeometric series. It is delightful to see how the discussion of these equations is illuminated by the general theory.

After a chapter on equations w th only some of their integrals regular, we come to the consideration of integrals with essential singularities. The most familiar example of a function with an essential singularity at a finite place is exp (x^{-1}), which is the integral of $x^2y' + y = 0$; and it is easy to see that if P is any polynomial in x^{-1}, the expression expP has an essential singularity and satisfies a linear equation of the first order.

Suppose now that we find that a given equation has an integral with an essential singularity at the origin; it may be possible to express it in the form $\exp P . x^\rho \psi(x)$, where ρ is constant and $\psi(x)$ holomorphic. Such an integral has been called "normal"; the discussion of these integrals, and others obtained by putting $x^{1/k}$ for x, is given in chapter vii., which contains important results due to Thomé, Hamburger, Poincaré and others. There is also a brief account of "double-loop integrals" after Jordan and Pochhammer, and of Poincaré's theory of asymptotic integrals.

In his paper on the motion of the moon, Hill was led to the solution of a linear equation by a method involving the use of infinite determinants. In chapter viii. Prof. Forsyth discusses this method in some detail, after giving a preliminary account of infinite determinants and their properties. The subject of this chapter is not very attractive in itself, but on account of its practical importance has naturally attracted a good deal of attention.

Chapter ix. deals with equations with uniform periodic coefficients, and gives an account of this part of the subject which ought to encourage young mathematicians to read the original sources and experiment on their own account. It is, of course, the equations with doubly periodic coefficients that are most interesting. Thanks principally to Hermite, Halphen and Picard, some extremely beautiful results have been already obtained in this field, and there can be no doubt that others are awaiting discovery.

The last chapter of this volume, on equations with algebraic coefficients, must have been very difficult to write, and appeals mainly to the specialist. Its principal topic is Poincaré's celebrated theorem that the integrals of any linear equation with algebraic coefficients can be expressed by means of Fuchsian and Zetafuchsian functions. As Prof. Forsyth justly remarks, we cannot hope to make practical use of Poincaré's theorem until the analysis of automorphic functions has reached a higher state of development. To this end the treatise by Klein and Fricke, now in course of publication, will doubtless contribute largely.

In conclusion, it may be well to remark that this volume is in great measure independent of its predecessors, and that a great part of it will be quite intelligible to junior mathematicians provided that they know the elements of the theory of a complex variable. To them, therefore, as well as to their seniors, this book may be heartily commended. G. B. M.

SCIENTIFIC PSYCHOLOGY.

Grundzüge der physiologischen Psychologie. Von Wilhelm Wundt. Fünfte völlig umgearbeitete Auflage. Erster Band. Pp. xv + 553. (Leipzig: W. Engelmann, 1902.) Price 10*s*. net.

THIS volume of 553 pages is the first of the three volumes in which the fifth edition of Prof. Wundt's great work is to appear. The rapid increase in size of the work in each of the successive editions is thus maintained in the present one, and, as in the case of the previous editions, has been necessitated by the rapidity of the growth of the youngest of the natural sciences, experimental or, as Prof. Wundt prefers to call it, physiological psychology. And even the increase in bulk of this book does not by any means fully express the rate of growth of the science, a growth towards which this country has contributed so lamentably little. For the book is primarily a record of the work and the views of the author and of his pupils in the great Leipzig school. Nevertheless, Prof. Wundt has found it necessary to rewrite almost the whole of the book, so that, as he tells us, it must be regarded as almost a new one.

The greater part of this first volume is concerned with matters not strictly psychological, but rather with those studies which form an essential part of the equipment of the psychologist, namely, the fine and coarse anatomy, the embryology and the physiology of nervous tissues, both special and comparative. It is, perhaps, open to question whether it is wise to attempt to treat so vast a range of subjects in the scope of a single volume. For

the psychologist may be tempted to content himself with the cursory review that is alone possible in such a work. It should certainly be possible nowadays for the writer on psychology to assume on the part of his readers a competent knowledge of the gross anatomy of the nervous system and of the principles of the conservation of energy. (In the anatomical section occurs an error that is, perhaps, of the nature of a slip. In Fig. 79 and in the accompanying text the uncrossed fibres of the optic nerves are represented as going to the nasal sides of the retinæ. Now although v. Kölliker and others still maintain that the decussation of the optic nerve-fibres in the chiasma is complete, and although there is some ground for believing that there occur considerable individual variations in the proportion of crossed and uncrossed fibres, yet all authorities agree that the uncrossed fibres go to the temporal sides of the retinæ.) The propriety of including an account of the general physiology of nerves is less open to question, the less so as Prof. Wundt is here on his own ground and can speak with authority. In this section Wundt makes a timely protest against the uncritical acceptance and wholesale application of Hering's doctrine of assimilation and dissimilation now so common among physiologists, and yet he teaches somewhat dogmatically a view that differs but little from the one he rejects. He too groups together under the term "inhibition" (Hemmung) all phenomena to which it can in any sense be applied, and assumes that one and all are manifestations of constructive metabolic processes, thus affording one more instance of the fact that the study of logic cannot prevent a man forming illogical conclusions. It cannot be too frequently pointed out that we have no evidence of active inhibitory processes within the nervous system and that all the numerous cases of "inhibition" may, and in the present state of knowledge should, be regarded as cases of interference or prevention only. Wundt goes so far as to assume a differentiation of the bodies of nerve-cells into two parts, the anabolic inhibitory and the katabolic augmentor parts, and applies this hypothesis to the explanation of the valve-like nature of the paths of the spinal cord. But although the hypothesis seems to have been devised in order to explain this phenomenon, it is not by any means clear that it can be made to do so.

The discussions of the functions of the cortex and especially of the "speech-centres" are admirably thorough and suggestive, and here Wundt gives a great development to the conception of a "brain-centre." It is, perhaps, to be regretted that he retains the term "centre," for it properly expresses a crude conception of which the period of usefulness is now at an end.

In treating of the fundamental constituents of psychical processes, Wundt distinguishes two fundamental kinds of psychical element, the sensations and the feelings (Empfindungen und Gefühle), the former including all those that have an objective reference and that are determined directly or indirectly by stimulation of sensory nerve-endings both within and on the surface of the body, the latter being the purely subjective elements. Compounded of sensations is the presentation (Vorstellung) and of feelings the emotion (Gemüthsbewegung). Wundt thus sets aside the old distinction of sensation and idea as that which is excited from without and from within respectively, asserting that the distinction is purely logical and not at all psychological. Though we may admit that Wundt's use of the terms is a convenient one, yet it is impossible to follow him in denying the psychological character of the distinction usually made by English authors, or to admit his claim that the occurrence of hallucinations, which are purely pathological states, necessitates this denial. If the distinction were not psychologically valid, if we did not immediately recognise in the presentation the peculiar quality of reality that distinguishes it from the representation, the term hallucination would have no meaning.

Perhaps the most interesting part of the volume is the discussion of the "law of specific nervous energies." This principle Wundt would replace by one which he declares to be directly opposed to it, and which he describes as "the principle of the adaptation of the sensory functions to the stimulus and of the sensory apparatus to the functions." This is based upon and assumes the truth of the following principles: that of the original similarity of function of all nerve-elements, which Wundt establishes by tracing in a most interesting manner the differentiation of the various senses from the general sensibility of the amœba upwards; the principle of the adaptation of nerve-elements through use or habituation; and the possibility, which we seem compelled to assume in some cases, that nerve-elements may come gradually to discharge the functions of others when those others are in any way rendered incapable of functioning. Now, admitting that the "law of specific nervous energies," as set up by Johannes Müller and by Helmholtz, is not in any sense an explanatory principle, but merely a *résumé* of a large group of facts, and admitting that it demands genetic treatment such as Wundt supplies, yet it is not possible to admit that even the most complete account of the evolution of the specific differentiations of sense can abolish the truths of which this "law" is the summary expression; to account for the origin of a thing or belief is not necessarily to explain it away. The fact remains that any specialised nerve of sense, when subjected to stimuli whether normal or abnormal, leads only to the kind of affection of consciousness peculiar to that sense. Wundt's account of the adaptations of the senses to stimuli is admirable and no doubt true so far as it goes, but it is far from being a complete explanation of the genesis of the specific functions.

Reducing the problem to its simplest terms, suppose a primitive sense-organ to be affected in the same way by two classes of stimuli, say two rates of vibration of the circumjacent medium—and then suppose that either rate of vibration comes in the course of evolution to determine a differentiation of one part of the nerves of the organ, so that one set of nerves comes to respond in one way to the one vibration-rate only and the other set in another way to the other (or that all the nerves come to respond in two distinct ways), and suppose the difference of response to consist in a difference in rate of vibration of the substance of the nerves, or in a difference of propagated chemical changes. Up to this point we may accept Wundt's account of the differentiation-process as adequate. But when we inquire—How comes it that the soul reacts to these two vibration-rates (or two kinds of chemical change) with two different

qualities of sensation? then we find ourselves still completely in the dark. Wundt himself seems to have felt this inadequacy and to have introduced in consequence towards the close of his exposition a new factor, the "entgegen kommende Triebe des empfindenden Wesen." This introduction of the "feeling being" amounts, it would seem, to nothing more than an admission of our ignorance. And indeed we have here reached the very kernel of the problem of life, of that mystery of the relations of soul and body which has vexed the thinkers of all ages, of that "master knot of human fate" of which the Persian poet wrote eight hundred years ago

> "There was the door to which I found no key,
> There was the veil through which I might not see."

And these words remain equally true to-day, in spite of the splendid labours of Johannes Müller, of Fechner, of Wundt and of many others.

It is interesting to note that Wundt assumes the principle of the inheritance of acquired characters as absolutely necessary to the explanation of the evolution of the nervous system, and that in this he is in agreement with most of the psychologists who have considered the problem. For the principle of natural selection, which is so satisfactory when we are dealing with the neck of the giraffe or the protective colouring of a butterfly, seems hopelessly inadequate when we have to account for those million-fold coordinated details of nervous disposition which together determine in large part, if not wholly, the tendencies and character of a human being.

In the last section Wundt deals with Weber's law and maintains his well-known psychological interpretation of it, in opposition to the now very generally accepted physiological interpretation. The attention of English readers may be called to the novel and ingenious explanation suggested by Heymans in the *Zeitschrift für Psychologie*, Bd. 26. W. McD.

THE MODERN DYNAMO.

The Generators of Electricity at the Paris Exhibition of 1900. By C. F. Guilbert. Pp. iv + 766. (Paris: C. Naud, 1902.) Price 30 fr.

THERE were probably few who went to the Paris Exhibition two years ago who did not pay a visit to the Palais d'Électricité; and no one who did so can have failed to have been impressed by the enormous size of the electric generators exhibited there. We even know of feminine sightseers, on pleasure bent, sparing a few hours from the fascinating display of M. Worth to look at, and possibly learn a little about, the "purrin' dynamos." The massive grandeur of these magnificent machines, examples of the best design and workmanship of all nations; the complicated nature of their parts working in perfect harmony and smoothness, and obedient to the control of one or two men; their spotless cleanliness and the impression of reserved power which they conveyed; all these must have moved even the most matter-of-fact observer into sympathy with the ideas which inspired Mr. Kipling to write "M'Andrew's Hymn." Such a collection merited the permanent record which it has obtained in the pages of M. Guilbert's book. Something of the spirit of the machines which he describes seems to have entered into the author, for his book, like the dynamos, is very large. There are nearly 800 pages, with, to use the author's own words, "615 engravings and plans, of which 118 plates." M. Guilbert has adopted a somewhat novel plan with the laudable desire of making his book attractive to foreign readers. The title pages and preface are in the language of the country in which the copy is to be sold; the chapter and section headings, the descriptions of the illustrations and the tables, are given in French, German and English. We rather doubt the wisdom of this innovation, since it increases the size of a volume already bulky, and still the most important part, the text, remains only in French. The result of the translation, too, is apt at times to be rather humorous, as, for example, when the author translates *résumé* (which the mere Englishman is content to use in the original French) into a non-existent English equivalent.

Criticism of a book of this kind is almost out of the question. M. Guilbert begins by describing the system of classification which he has adopted, and then, taking each division in turn, gives a more or less detailed description of the principal exhibits which come within it. Photographs of the generators and clearly executed diagrams of the whole machine or of important details greatly help out the letterpress. The book is therefore, in a way, like a descriptive catalogue, but it is one which gives a large amount of very valuable information, and M. Guilbert deserves great credit for the painstaking way in which he has collected and the clear manner in which he has arranged the data supplied by the manufacturers. It may be objected that the work is two years out of date and that the machines of 1900 are almost ready for the scrap heap in 1902. But rapid as the advance of electrical engineering is, there are few engineers who will not benefit to-day by the careful study of what was best two years ago, especially as it is the best, not of one country only, but of all countries; there will be many also interested in the design and improvement of electric generators who will desire to possess this book, even though it should become in the course of a few years of historical interest only.

As we turn over the pages of M. Guilbert's book, we find difficulty in selecting any particular machine for special notice. As the most noticeable feature in dynamo development in recent years has been the steadily increasing size of the unit, we may perhaps be pardoned if we pick out one of the largest machines exhibited at Paris. The Allgemeine Elektricitäts Gesellschaft exhibited a three-phase alternator of 4000 h.p. The output of this machine was 3000 kilovolt-amperes with a power factor of 0·9, making 2700 kilowatts. This alternator is one of a set of twenty-two, eight of which are already installed at the Berlin Electricity Works, the remaining thirteen being under construction. To bring this machine to Paris and to erect it in the German annexe, where there was no travelling crane, was a work of no small difficulty. The total weight was 160 tons, the armature frame weighing 80 and the field magnet 70 tons, the remaining 10 tons being due to the bedplate. The armature and field magnet were brought to the exhibition in quarters, each quarter being carried mounted between two railway trucks in the position most suited

for its subsequent erection. The whole work of erection was successfully completed in three weeks.

The A.E.G. alternator was not in actual operation at Paris, but was rotated for exhibition purposes by a small motor. An equally large generating set was exhibited by the Helios Company, driven by a triple-expansion engine and used for the lighting of the exhibition. This machine was of special design, as the makers desired to satisfy the requirements of the exhibition authorities and also to make the alternator suitable for subsequent disposal for other purposes. Another alternator of special interest was that exhibited by the Société l'Éclairage Électrique, which generated at 30,000 volts. This was designed more as an experimental machine, to show the possibility of directly generating at very high pressure and so dispensing with step-up transformers. The alternator had only an output of 180 k.v.-a. It is interesting in this connection to recall that last February Messrs. Schuchert and Co. completed three 1500 kw. three-phase alternators generating at 20,000 volts, for supplying power to the Valtellina Railway.

M. Guilbert has collected together all the chief data of the various machines in ten tables as an appendix at the end of the book. There is also given as an appendix a series of twenty oscillograph curves showing the potential wave-forms of a number of the alternators. These, which were taken by means of M. Blondel's oscillograph, though very interesting, are hardly accompanied by sufficient data to make them of great value. A casual inspection is, however, sufficient to show that, as M. Guilbert remarks, much progress remains to be made in the construction of alternators before a practically sinusoïdal potential-curve is obtained. Yet though much remains to be done, much has already been accomplished, and the manufacturer of the modern dynamo has nothing of which to be ashamed. His machines are efficient, and he has shown that he is capable of making them of a size suitable to the ever-increasing requirements, and there can be little doubt that when the time arrives he will be able to meet still greater demands. It is not likely to be long before these are made, especially for generators for traction work. But a year or two ago the Westinghouse Company built two 2700 kw. generators for the Boston Elevated Railway; one is inclined to ask what the size of the units will be when, say, the London and North-Western or the Canadian Pacific Railway is run electrically. We can only hope that it will not be long before an answer has to be given to his question; that our progress in the future will be as rapid and as sound as it has been in the past; and that the next seventy years will be as full of development and improvement as have been the seventy which have passed since Faraday "did not despair of being able to construct a new electrical machine." M. S.

OUR BOOK SHELF.

Thirteenth Annual Report of the Local Government Board, 1900–1. Supplement containing the Report of the Medical Officer for 1900–1. (London: Eyre and Spottiswoode, 1902.)

THE scientific memoirs contained in this volume are of considerable interest. Drs. Klein and Houston have investigated the behaviour of pathogenic organisms when inoculated upon various farinaceous media, and conclude that the likelihood of infection of the human subject from such source is probably remote. A number of food-stuffs were similarly examined by Dr. Klein for the presence of pathogenic organisms, with the result that none was found. Dr. Gordon has continued his studies upon the bacteriology of scarlatina, and he adduces further proof that the *Streptococcus scarlatinae* is a species distinct from other streptococci and that it may be the causative organism of this disease. Two papers are concerned with the behaviour of micro-organisms when inoculated into the soil. In the first, Dr. Houston inoculated soil with crude sewage, and found that on the whole the soil-microbes ousted the sewage ones and that the addition of sewage to soil resulted in a temporary increase only of the sewage microbes. In the second, Dr. Sidney Martin has continued his work upon the nature of the antagonism of the soil to the typhoid bacillus; this organism survives but a short time in the soil, being destroyed by the products of the putrefactive bacteria which exist therein. Dr. Klein also reports on the infection of cockles and mussels with the typhoid and cholera microbes, and shows that these organisms may persist in the interior of the molluscs for some time after the source of infection has been removed. The importance of rats in the dissemination of plague has induced Dr. Haldane to devise an apparatus for generating carbonic oxide gas for destroying these pests in plague-infected ships. This is described and some experiments with it are detailed. There is also an interesting report upon research work in connection with glycerinated vaccine lymph. The volume concludes with a number of well-executed photographs illustrating the various papers. R. T. HEWLETT.

The Flora of the East Riding of Yorkshire. By J. F. Robinson. Pp. vii + 253. (London: A. Brown and Sons.) Price 7*s.* 6*d.*

THE "Flora of the North Riding of Yorkshire," compiled by Mr. J. G. Baker so long ago as 1863, furnishes a delightful account of the plants and the plant-associations of that division. Dr. F. A. Lees is responsible for a "Flora of the West Riding" which is equally successful. The present work, therefore, fills up an important gap and completes the botanical survey of the county. The enumeration of plants is preceded by a historical review of earlier compilations and a series of sketches referring to the physiography, meteorology and plant distribution of the district. These, taken in combination with the geological map, add greatly to the interest of the book. At the same time, these chapters seem capable of some improvement. The physiographical chapter brings out very clearly the interesting features of the division, the ancient lake-area now represented by a single lake and patches of marsh in the plain of Holderness, the estuary of the Humber, the Cretaceous formation of the Wolds and the mixed character of the deposits in Derwent-land. But the ecological chapter suffers by being too condensed, and "xerophiles," "pelophiles," "arenophiles" are tumbling over one another. The contrast of "xerophiles" and "pelophiles" on pp. 35, 39, represents a confusion of terms. A more detailed and localised account of the plant forms on the different alluvial deposits and an extension of the very brief indication of successive littoral colonies, as well as fuller descriptions of other local formations, might well be given, and the extra space could be more than gained by a less generous use of type and spacing in the flora proper. In the enumeration of plants, the author and his colleagues have endeavoured to sift out the aliens which are especially abundant round Hull Docks, and also the recorded localities have received personal confirmation as far as possible. The author and the Hull Scientific and Field Naturalists' Club deserve the thanks of botanists for a

compilation which represents much hard work and which will serve to stimulate interest in that division of the county, inasmuch as it indicates a somewhat unexpected wealth and variety of plant forms. Mr. J. J. Marshall has furnished a list of the mosses of the Riding.

A Revolution in the Science of Cosmology. By George Campbell. Pp. 210. (London: Sampson Low, Marston and Co., Ltd., 1902.)

IN spite of the author's description of himself as "a professor and teacher of the natural sciences for many years," this attempt to revise the generally accepted theory of planetary evolution shows a very imperfect acquaintance with scientific principles. The leading idea is that the earth was never in a molten condition, but is now undergoing the process of fusion in consequence of the pressure of the external strata on the interior mass. The sun also is declared to have once been an opaque body, and to represent more or less what the earth and other planets will become. In this connection it is only necessary to point out that while a gaseous mass contracting under the influence of its own gravity will rise in temperature, there is no ground for extending this principle to masses which are liquid or solid.

Among the other unacceptable ideas met with is that which accounts for a prehistoric change in the polar climate by supposing that the North Pole of the earth was "suddenly" turned from the sun and remained in that position for ages, having ceased for the time being to rotate on its axis (pp. 35 and 140). Again, on p. 64, speaking of the Whirlpool nebula, it is stated that "the violent agitation of the mass must result in a very low temperature," whereas a high temperature would be expected.

The author appears to have a vague idea that electricity plays an important part in the development of worlds, and that "atoms of interstellar space" represent the primary state of all matter, but he makes no contribution of value to the subject.

The Reliquary and Illustrated Archaeologist. Edited by J. Romilly Allen. Vol. viii. Pp. 287. (London: Bemrose and Sons, Ltd., 1902.) Price 12*s.* net.

STUDENTS of any branch of archæology will find something to interest them in this volume. The periodical, of which the numbers issued during the present year are included in the volume, is "a quarterly journal and review devoted to the study of the early pagan and Christian antiquities of Great Britain; mediæval architecture and ecclesiology; the development of the arts and industries of man in the past ages; and the survivals of ancient usages and appliances in the present." Notes on interesting and important papers contributed to some of the separate numbers of the *Reliquary* have already appeared in these columns, so that it is only necessary to say here that the eighth volume, with its numerous, well-produced illustrations, would make a handsome addition to the library of the student of antiquities.

Earth and Sky. A Second and Third Grade Nature Reader and Text-Book. By. J. H. Stickney. Pp. viii + 118. (Boston, U.S.A., and London: Ginn and Co., 1902.) Price 1*s.* 6*d.*

THIS is a reading book for young children. Its object is, the author says in his preface, "to bring before children's minds their own relation to the natural world in such a way as to appeal to imagination and reflection." The lessons will probably prove interesting to those for whom they are intended, but they do not sufficiently encourage the child's own activity. It is not enough to tell young pupils about natural objects; they should be encouraged to observe for themselves, instead of being content with the descriptions of others.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Waste of Energy from a Moving Electron.

THE subject of the dynamics of a moving charge being of considerable interest now, I have thought the following may be useful. I have shown that a charge Q on a sphere of radius A, when suddenly jerked into motion at speed u, generates a spherical electromagnetic shell of depth 2A, in which the magnetic force H tends to the value given by

$$2AH = \frac{Q}{4\pi R} \frac{u \sin\theta}{1 - \frac{u}{v}\cos\theta}, \qquad (1)$$

when R, the distance from the initial centre of Q, is great. Along with this H, we have perpendicular electric force in the shell, according to $E = \mu v H$, or vectorially, $\mathbf{E} = V\mathbf{vB}$, if $\mathbf{v}$ is the vector velocity of the shell. The angle θ is that between $\mathbf{u}$ and $\mathbf{R}$. The energy wasted by this shell equals the energy left behind, that is, $U - U_0 + T$, if U_0 is the initial, U the final electric energy in the field, and T the final magnetic field energy. On its first formation, $\mathbf{H}$ and $\mathbf{E}$ in the shell are different; they then include in accumulated form all the $\mathbf{H}$ and $\mathbf{E}$ which are left behind by the shell as it expands. The applied force impulse follows from my formula for the force on the ether, viz. $\mathbf{F} = (d/dt)V\mathbf{DB}$ per unit volume. Denoting the time integral by $\mathbf{M}$, then $\mathbf{M} = \mathbf{M}_1 + \mathbf{M}_2$, where $\mathbf{M}_2$ belongs to the shell ultimately, and is lost, whilst $\mathbf{M}_1$ is left behind in the field. We have $T = \frac{1}{2}M_1 u$ and $U - U_0 = \frac{1}{2}M_2 u$; so that altogether

$$\tfrac{1}{2}Mu = U - U_0 + T. \qquad (2)$$

Both $\mathbf{M}_1$ and $\mathbf{M}_2$ are parallel to $\mathbf{u}$.

If, now, a second impulse acts, changing the velocity from $\mathbf{u}_1$ to $\mathbf{u}_2$ say, another spherical shell is generated. Disregarding the part left behind, (1) above shows that the magnetic force in it is

$$2AH = \frac{Q}{4\pi R}\left(\frac{u_2 \sin\theta}{1 - \frac{u_2}{v}\cos\theta} - \frac{u_1 \sin\theta}{1 - \frac{u_1}{v}\cos\theta}\right), \qquad (3)$$

when the direction does not change. More generally, substitute the vector change in the quantity on the right side of (1) properly vectorised. Then the change in θ will be allowed for as well.

The energy lost in this second shell may be calculated by (3). It amounts to

$$\left\{\frac{u_2 P_2 - u_1 P_1}{u_2 - u_1}\left(1 - \frac{u_1 u_2}{v^2}\right) - P_0\right\} Q, \qquad (4)$$

where P is the potential function

$$P = \frac{Q}{4\pi Ac}\left(1 + \frac{1}{3}\frac{u^2}{v^2} + \frac{1}{5}\frac{u^4}{v^4} + \ldots\right) \qquad (5)$$

investigated by Searle and Morton. Take $u = 0$, u_1 and u_2 to obtain P_0, P_1, P_2. It may be shown that the substitution of two impulsive changes in the same direction for a single one reduces the waste; that is, the one impulse u_2 wastes more energy than the two successive impulses u_1 and $u_2 - u_1$. In fact, the saving is great, and ten equal partial impulses in succession waste not much more than one-tenth part of that wasted by a single impulse of size equal to their sum. There is a residuum, however, and that is what appears as continuous waste when u varies continuously.

When Δu is small

$$2AH = \frac{Q}{4\pi R} \frac{\sin\theta\,\Delta u}{\left(1 - \frac{u}{v}\cos\theta\right)^2}, \qquad (6)$$

and now the waste of energy in the shell wave corresponding to Δu is

$$\frac{\mu Q^2}{12\pi A} \frac{(\Delta u)^2}{\left(1 - \frac{u^2}{v^2}\right)^2}. \qquad (7)$$

The magnetic force in the above shells is uniform in the depth of the shell, when the impulse acts strictly at the front of a shell.

But if Δu be distributed uniformly over the time $2A/v$, the shell will be doubled in depth, and H will rise at uniform rate from 0 to the same full value in the middle of the shell and then fall similarly to zero in the second half. Now if a second equal Δu acts in the same way, beginning as soon as the first Δu has made H reach full strength, H will continue of that full strength. And so on with a third Δu. Finally, if $2A = v\Delta t$, and $\Delta u/\Delta t$ is steady, and allowing for the variable depth of the shell according to (11) below, we come to

$$\Delta t \cdot \frac{\mu Q^2}{6\pi v}\left(\frac{\Delta u}{\Delta t}\right)^2 \frac{1}{\left(1-\frac{u^2}{v^2}\right)^3}, \tag{8}$$

to represent the waste in time Δt. Or, if W is the rate of waste

$$W = \frac{\mu Q^2}{6\pi v}\left(\frac{du}{dt}\right)^2 \frac{1}{\left(1-\frac{u^2}{v^2}\right)^3}. \tag{9}$$

This holds when the acceleration and the velocity are parallel. By the manner of construction, it is necessary that du/dt should not vary sensibly in the time taken by light to traverse the diameter 2A.

By a fuller analysis, allowing for change of direction of motion, I find that the waste of energy per second from a charge Q with velocity **u** and acceleration **a** is

$$W = \frac{\mu Q^2 a^2}{6\pi v} \frac{1 - \frac{u^2}{v^2}\sin^2\theta_1}{\left(1-\frac{u^2}{v^2}\right)^3}. \tag{10}$$

when θ_1 is the angle between the velocity and acceleration (absolute). The dimension A does not appear. W is the same for any size, subject to the restriction mentioned. The smaller A the better, of course. It is exactly true with $A = 0$, only then the motion would be impossible.

This calculation of the waste may be confirmed by following up my investigation of the electric and magnetic field by the method I gave in 1889 ("Elec. Pa.," vol. ii. p. 504).

The waste is greatest when the velocity and acceleration are parallel, and least when perpendicular. There is another reservation, viz. u must be less than v. If not, special treatment is required, after the manner I have already published.

The meaning of waste is this. When Q moves through the distance udt, it casts off a spherical shell of depth

$$\frac{vdt}{1 - \frac{u}{v}\cos\theta} \tag{11}$$

and the energy of this shell when it has gone out to an infinite distance is Wdt.

When at a finite distance, **E** and **H** in this elementary shell are given by

$$\mathbf{E} = \mathbf{E}_1 + \mathbf{E}_2, \qquad \mathbf{H} = \mathbf{H}_1 + \mathbf{H}_2,$$
$$\mathbf{H}_1 = \mathrm{V}\mathbf{u}\mathbf{D}_1, \quad \mathbf{H}_2 = \mathrm{V}\mathbf{v}\mathbf{D}_2, \tag{12}$$

$$\mathbf{E}_1 = \frac{Q}{4\pi R^3 c}\, \frac{\mathbf{R} - \frac{\mathbf{u}}{v}R}{\left(1 - \frac{u}{v}\cos\theta\right)^3}. \tag{13}$$

$$\mathbf{E}_2 = -\frac{\mu Q}{4\pi R}\left\{\frac{\mathbf{a}}{\left(1-\frac{u}{v}\cos\theta\right)^2} - \frac{a\left(\mathbf{R} - \frac{\mathbf{u}}{v}R\right)\cos\phi^1}{\left(1-\frac{u}{v}\cos\theta\right)^3}\right\}. \tag{14}$$

Here the part $\mathbf{E}_1$, $\mathbf{H}_1$ belongs to the steady travelling state of steady **u**, whilst the other part $\mathbf{E}_2, \mathbf{H}_2$ is electromagnetic, and represents the waste. The angle between the acceleration **a** and **R** is ϕ^1. The waste part has $\mathbf{E}_2, \mathbf{H}_2$ tangential, that is, perpendicular to **R**. $\mathbf{H}_1$ is also tangential to the sphere, but $\mathbf{E}_1$ is radially directed from the point which Q would reach at the moment in question (belonging to the sphere R) if it were not accelerated at all. This means the steady travelling state (see "El. Pa.," vol. ii. p. 511, equation 29). There is another way of treating the question, viz. by the vector and scalar potentials. The vector potential of the impressed current $Q\mathbf{u}$ is not $Q\mathbf{u}/4\pi R$, but (*loc. cit.*)

$$\mathbf{A} = \frac{Q\mathbf{u}}{4\pi R\left(1 - \frac{u}{v}\cos\theta\right)}. \tag{15}$$

This is referred to origin at the virtual position of the charge, not the actual. The actual is best for the steady state, the virtual to show the waves emitted. The factor $(1 - u/v\cos\theta)^{-1}$ expresses the Doppler effect. Divide by $\mathbf{u}c$ to obtain the scalar potential Φ. Then

$$\mathbf{H} = \text{curl } \mathbf{A}, \qquad \mathbf{E} = -\mu\dot{\mathbf{A}} - \nabla\Phi$$

in Maxwell's manner. The trouble here is the differentiations, which require great care, since **u**, **R** and θ all vary in a rather complicated way as Q moves. The relations (12) exhibit the field clearly.

For an infinitely small sphere of Q, the energies in the shell at distance R corresponding to the displacement udt of Q are

$$T = T_1 + T_2 + 2T_{12},$$
$$U = U_1 + U_2 + 2U_{12},$$

where $_1$ relates to the $\mathbf{E}_1\mathbf{H}_1$ part and $_2$ to the other part, whilst $_{12}$ refers to the mutual energy. They are connected thus:

$$U_2 = T_2, \quad U_{12} = T_{12}, \quad U_1 = T_1 + \frac{Q^2 vdt}{8\pi R^2 c}, \tag{16}$$

$$T_1 = \frac{Q^2 vdt}{12\pi R^2 c}\,\frac{u^2/v^2}{\kappa^2}, \quad T_{12} = \frac{\mu Q^2 a}{12\pi R}\,\frac{udt\cos\theta_1}{\kappa^4}, \tag{17}$$

$$T_2 = \frac{\mu Q^2 a^2 dt_1}{12\pi v}\,\frac{1 - \frac{u^2}{v^2}\sin^2\theta_1}{\kappa^6}, \tag{18}$$

where $\kappa^2 = 1 - u^2/v^2$.

The corresponding "momenta," or force-impulses, say $\mathbf{M}_1 = \Sigma\mathrm{V}\mathbf{D}_1\mathbf{B}_1$, $\mathbf{M}_2 = \Sigma\mathrm{V}\mathbf{D}_2\mathbf{B}_2$, $\mathbf{M}_{12} = \Sigma\mathrm{V}\mathbf{D}_1\mathbf{B}_2$, $\mathbf{M}_{21} = \mathrm{V}\mathbf{D}_2\mathbf{B}_1$, are given by

$$\mathbf{M}_1 = \frac{2T_1}{\mathbf{u}}, \quad \mathbf{M}_2 = \frac{2T_2\mathbf{u}}{v^2}, \quad \mathbf{M}_{21} = \frac{2T_{12}\mathbf{u}}{v^2}. \tag{19}$$

These are all parallel to **u**. But $\mathbf{M}_{12}$ is not, though it is in the plane of **u** and **a**. Its components parallel to **u** and to **a** are

$$\frac{2T_{12}}{u}, \quad\text{and}\quad \frac{2T_{12}}{u}\,\frac{1 - \frac{u^2}{v^2}\sin^2\theta_1}{\cos\theta_1}. \tag{20}$$

With the previous restriction, these are independent of the size of the sphere of Q. But to obtain exact formulæ without this restriction, either a very difficult integration must be effected over the surface of the sphere of Q, every element of which will usually have (effectively) a different velocity and acceleration, on account of the Doppler effect, or we may derive the resulting formulæ by a differentiating operator. Thus, for example, exhibiting it for Φ only, let Φ_0 be the formula when $A = 0$, then the real Φ is, by a previous investigation,

$$\Phi = \frac{\text{shin } qA}{qa}\Phi_0, \tag{21}$$

outside the sphere, and

$$\Phi = \frac{\text{shin } qr}{qr}\Phi_{0A}, \tag{22}$$

inside the sphere, where q is the differentiator $d/d(vt_1)$ and Φ_{0A} is the common value of both Φ's at $R = A$. But this t_1 is not the same as the previous t; it is the corresponding value; the place where the differentiations are performed is at the end of **R**. The differentiations are troublesome. Thirdly, we may calculate the time integral of Φ_0, and then apply Taylor's theorem. Nearly all the trouble in the electronic theory is connected with the necessity of making A finite to have finite energy (though this does not apply to the waste) and finite moving forces, with the consequent resulting two superposed waves, one outward from the surface of Q, the other inward, and then outward again. The results for impulses work out easily enough, but not for continuous accelerations.

Details of the above will be published in vol. iii. of "Electromagnetic Theory" (and perhaps elsewhere), which is, as the advertisement says, "in preparation."

Returning to the waste formula, an electron revolving in a circle of radius r has $\theta_1 = \frac{1}{2}\pi$, and $u^2/r = a$. So we want an applied force along **u** varying as u^3 to maintain the motion, since the waste varies as u^4. This revolving electron has sometimes been supposed to be a circular current. But it is really a vibrator. The free path followed under decay of energy without fresh supply would perhaps be difficult to follow

completely. It is rather hard for the "explanation" of magnetism.

The kinetic energy of molecules is the natural source of the radiation, but the connection between them and the electrification is very obscure, and how the electrons get knocked off is harder still, and what they are is hardest of all. Larmor thinks they run through the ether like knots on a string. If they do, as they may, *how* do they do it? Connections are wanted.

OLIVER HEAVISIDE.

Leonid Meteors, 1902. A Forecast.

THE historical interest which attaches to the Leonid star showers naturally renders the near approach of mid-November a subject of paramount importance to meteor observers. Nor is expectation lessened on the present occasion by the moderate though somewhat unexpected brilliance of the Leonid display witnessed last year in America on the morning of November 15. The question must naturally occur to many, will there be a revival of the phenomenon in the November of 1902, and if so, will it make its appearance in a less or a more intensified form than in the previous year? Generally speaking, the prospects of a star shower on the night of November 15 this year are very good. An analysis made by the writer of the conditions under which last year's shower appeared, and also of those connected with the more brilliant meteoric spectacles of the past, shows that the event of November 15, 1901, is likely to be much surpassed by the meteoric phenomenon of 1902. The display falls due on the night of November 15 on the present occasion, and not on that of November 14 as was the case last year and was duly predicted by the writer (*Daily Chronicle*, November 14), though the maximum occurred somewhat later on that night than had been expected. The first phase of the shower will take place, however, at an hour not very well suited for its observation in western Europe, the time of its maximum being November 15d. 10h. 45m. G.M.T., when the radiant will be not much more than just above the horizon. Meteors from a radiant in full activity as it emerges above the horizon afford an interesting spectacle, however, and though their numbers must in consequence be seriously diminished, they somewhat atone for their paucity by often long and rapid flights across the heavens. This first appearance of the shower will of course be best observed in places situated at least a few hours to the east of Greenwich, though it ought not to escape observation in our less favoured localities. This early display promises to vie in brilliancy with that observed on the western slopes of the Pacific in 1901, if atmospheric conditions turn out favourable in those places best suited for its observation on the night of November 15, and in all places where the radiant will be above the horizon at the time of its maximum it ought to render shooting stars pretty abundant during the early hours of that night.

The second maximum of the Leonid display has been calculated to take place on November 15d. 18h. 45m., and promises to be the richest display of the night, though the time of its highest brilliancy will scarcely enable observers to obtain the most satisfactory view of it on this side of the Atlantic, as the increasing twilight between six and seven o'clock in the morning must somewhat impede observation. Along the eastern coast of America, on the other hand, the shower is likely to prove an attractive spectacle to observers, and its full strength can better and more accurately be subjected to calculation than with us, as its maximum will occur there at about two o'clock (local time) on the morning of November 16. Though that hour is rather early for its best observation, as the Leonid radiant is most favourably situated for purposes of meteoric observation in any place at about 4 o'clock in the morning (local time), yet on the present occasion at no other place can a better and more systematic watch be maintained for the anticipated star shower than along the Atlantic side of the American continent. Passengers on vessels crossing the Atlantic will no doubt find themselves specially favoured with opportunities for observing the phenomenon, as has been the case in previous star showers, such as that of 1868. The calculations made with respect to this meteor display go to prove that it will decline rather rapidly after 18h. 45m. on the night of November 15, the maximum showing a tendency to occur rather before th n after the time indicated, and on this account shooting stars are very likely to appear in unusual numbers to European observers throughout the night in question. As has been already stated, the shower expected in the present year gives considerable promise of surpassing in intensity that of 1901. Indeed, the calculated strength of the former is from ten to fifteen times that of the latter, but the presence of a full moon throughout the night of November 15 has not been taken into account in the determination of the foregoing comparison, and this circumstance must detract considerably from the relative splendour of the meteoric epoch of the present year. The full moon will probably obliterate the close of this year's shower, the end of which has been timed to take place on November 16d. 2h. 30m., and is generally of too weak a character to require any special consideration. It may be added that the foregoing calculations have been based on the assumption that the maximum of the Leonid shower of 1866 occurred at 1h. 15m. on the morning of November 14, G.M.T.

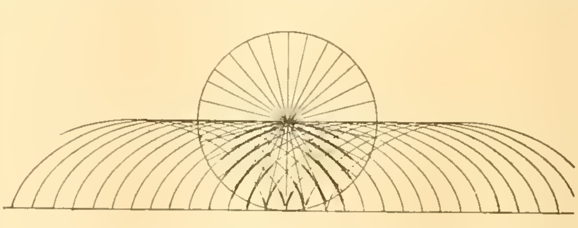
Curvature of Wheel Spokes in Photographs.

MANY people must have noticed the curious curved appearance presented in a photograph by the spokes of a moving vehicle. It is well known that the envelope of a diameter of a circle rolling along a straight line is a cycloid of half the dimensions of the cycloid traced by a point on the circumference. The part of the moving spoke which makes the strongest impression on the photographic plate will be where it intersects the consecutive position, so that the photograph really gives us

a small piece of the envelope of each spoke. The effect may be compared to the ordinary caustics of reflection or refraction. The accompanying photograph shows, not only the curvature of the spokes, but also the cusps of the envelopes of the spokes the ends of which have touched the ground during the exposure. In the diagram, the envelopes for a circle with fourteen equidistant diameters are drawn, and the parts of the envelopes which have



been put in strongly indicate the appearance that would be presented in a photograph, supposing that three spokes had touched the ground during the exposure. The spokes on the upper half of the moving wheel leave no impression on the plate, because their points of ultimate intersection lie *outside* the spokes themselves.

The Turkestan Earthquake of August 22.

INFORMATION received in India leaves no room for doubt that the earthquake of August 22, which left such conspicuous traces on the seismographs of Europe, had its origin in Central Asia. The representative of the Indian Government at Kashgar reports that there was a severe earthquake there at 8 a.m. on August 22, which lasted one-and-half minutes. Repeated

shocks were felt throughout the day, and shocks are reported on every day up to August 30. At 10 p.m. on September 2, a very sharp and severe shock was felt. It is said, though this has probably no direct connection with the earthquake, that the disturbance was followed by extreme heat, which lasted, at any rate, to the end of the month.

At Kashgar a good number of walls, made of sun-dried bricks, were knocked down, but masonry buildings do not seem to have suffered; sixteen deaths are said to have occurred through falling of houses. In the Artush district, to the north of Kashgar, the damage was much greater; nearly all the houses—presumably built of sun-dried brick—are said to have collapsed, and 667 deaths are known, besides more than 1000 persons severely injured. In Russian territory north of the Tian Shan range the shock appears to have been less violent, and it is reported that the damage done at Narin and Atbashi was not great. In the opposite direction the shock was felt at Yarkand, whence three shocks are reported to have been felt between 9 and 10 a.m. Some damage was done to the city wall and some private buildings; two children were killed by walls falling on them.

These particulars are sufficient to show that the earthquake was one of the first order of magnitude. Yarkand and Narin, at both of which it was destructive, are about 240 miles apart in a straight line, but are not sufficient to determine with certainty the position of the epicentre. This was evidently either to the east-north-east of Kashgar or more probably to the west-north-west among the mountains of the Alai Tian Shan range. It may consequently be taken that this earthquake, which will probably never be the subject of a detailed study, originated in about lat. 40° N., long. 74° E. of Greenwich.

Calcutta. R. D. OLDHAM.

Lectures on Anthropology and Ethnology.

THE letter of "Anthropotamist" in your issue of October 30 ought to meet with general approval.

In mentioning the educational institutions at which anthropology and ethnology are taught, your correspondent has entirely omitted London.

May I point out that courses of lectures in these subjects have been established at this college for the past two years, and have been attended by upwards of thirty students? Of these, two have previously contributed papers to the *Philosophical Transactions* and *Biometrika* dealing with questions of physical anthropology, while a third is the author of a volume treating of one phase of ethnology. It may be fairly claimed that to this college belongs the credit of being a pioneer in the systematic teaching of this subject in London.

Bedford College for Women (University of London), November 2.

THE ROYAL SOCIETY'S CATALOGUE OF SCIENTIFIC PAPERS.

THE following memorandum has been issued by the treasurer of the Royal Society:—

The Royal Society has been engaged continuously during the past forty years in cataloguing the various scientific papers which have been issued in all parts of the world since the beginning of the last century. The original scheme of the Catalogue of Scientific Papers provided that the papers should be catalogued only under the names of their respective authors arranged alphabetically. This "Authors' Catalogue" has now been carried down to the end of 1883, and comprises twelve quarto volumes.

More recently it has been decided to prepare also a subject index of the same papers, that is to say, a catalogue in which the papers are indexed according to the subject-matter of which they treat. Considerable progress has been made with this subject index, though nothing has as yet been published.

The expense of this work has been very large; since, although a great amount of gratuitous labour has been readily given by Fellows of the Society, it has been necessary to employ a considerable permanent salaried staff upon the preparation of the copy for the press. At first the printing and publication were undertaken by H.M. Stationery Office, the Treasury having determined that the Catalogue should be printed at the public expense. In coming to this conclusion, the Lords of the Treasury stated that they had regard "to the importance of the work with reference to the promotion of scientific knowledge generally, to the high authority of the source from whence it came, and to the labour gratuitously given by members of the Royal Society for its production." This arrangement, however, came to an end after the publication of the first eight volumes. The Treasury, in 1889, informed the Society that the Catalogue could no longer be printed and published by the Stationery Office. The unsold volumes were, however, handed over to the Society, and Parliament voted a sum of 1000*l.* to assist the Society in continuing the printing and publication. The four subsequent volumes have been printed and published by the Cambridge University Press, which has received subsidies from the Society for this purpose and receives the sums arising from sales.

The total sum expended by the Society upon the Catalogue down to the end of June last has been 14,790*l.* 5*s.* 5*d.* Towards this expenditure a donation of 2000*l.* was made by Dr. Ludwig Mond in 1892. Sums amounting to 524*l.* 11*s.* 9*d.* have been received as the proceeds of sales of the volumes handed over to the Royal Society by the Stationery Office, and, as already stated, 1000*l.* has been received from the Treasury. The Council has also hitherto devoted the income of the Handley fund (which they have power to apply as they may deem best for the advancement of science) towards defraying the cost of producing the Catalogue. The total sum received from this source has been 2394*l.* 11*s.* 10*d.* A sum of 341*l.* 11*s.*, arising from money invested until actually required, has also been available for the same purpose. These pecuniary aids amount in all to 6260*l.* 14*s.* 7*d.* As will be seen, they have not been nearly sufficient to meet the whole cost, and the Society has been compelled to make up the balance of 8529*l.* 10*s.* 10*d.* out of its general income.

As it became obvious that to continue permanently to prepare and publish catalogues of the ever-increasing stream of scientific literature was wholly beyond the means of the Society, the Council took steps to obtain international cooperation in this great work. Such cooperation has happily been secured, and the cataloguing of the scientific literature of the present century is now in the hands of an international council. The Royal Society has, however, incurred large special responsibilities in connection with the matter, having undertaken, *inter alia*, to act as the publishers of the Catalogue, and also to advance the capital required to start the enterprise.

The International Catalogue is concerned only with the scientific literature appearing after the commencement of the present century. The Royal Society's Catalogue, as already stated, is at present carried down to the end of the year 1883 only, and the subject index for that period is but partially dealt with. The foreign delegates, assembled to consider the establishment of the international council, expressed their sense of the great importance of the Royal Society's Catalogue and of the obligations which men of science in all countries were under to the Society for having undertaken it. They also expressed the hope that the Society would complete the Catalogue up to the close of the last century, so as to bring it into line with the International Catalogue.

In order to complete the Catalogue, it will be necessary to prepare and publish a catalogue of authors for the seventeen years 1883–1900, and to complete and publish the subject index for the whole of the past century. The Council of the Royal Society are satisfied that this work must be done, and have not felt justified

in refusing to undertake it. They have accordingly commenced operations, and it is hoped that the copy may be produced ready for the press in about five years. Owing to the enormous increase in the number of scientific publications at the close of the last century, it is estimated that to complete the Catalogue and to subsidise a publisher for undertaking the printing and publication, he retaining the proceeds of the sale, will cost at least 12,000*l.*

The question now arises whether the funds of the Royal Society ought to continue to be burdened with any part of this expense. The activity and responsibilities of the Society have greatly increased in recent years, and it is much straitened by its inability to increase its expenditure, either on its own establishment or in other directions, owing to the incessant demands of the Catalogue. The Council consider that the time has now come for them to appeal to those who are in a position to afford substantial financial assistance, to enable them to complete this great undertaking without devoting any part of their funds, so sorely needed for other purposes, to this object. They are thankful to be able to announce that Dr. Ludwig Mond, F.R.S., has been so impressed with the importance of the Catalogue, with the necessity for producing the subject index of the scientific literature of the past century so far as possible in the same complete form as that adopted by the International Council for the literature of the present century, and with the justice of the view that the Royal Society ought for the future to be relieved of the cost of producing the Catalogue, that he has most generously added to his previous gift of 2000*l.* the munificent donation of 6000*l.*, payable in four annual instalments of 1500*l.*

The President and Council have also much pleasure in stating that Mr. Andrew Carnegie, fully appreciating the value of the Society's undertaking and the claims that it has on the liberality of those who, though not Fellows of the Society, are interested in the promotion of natural knowledge, has contributed the handsome sum of 1000*l.* towards its accomplishment. They venture to hope that others may be willing to contribute towards a fund to provide for the total cost of this national work.

November, 1902.

THE BERLIN TUBERCULOSIS CONGRESS.

THE Congress on Tuberculosis, which has recently concluded its sittings in Berlin, was instituted under the auspices of the Central International Organisation for the Prevention of Consumption, which is itself an outcome of the international congresses which have met during recent years in Paris, Berlin, Naples and London. An international association of this kind is to some extent a new departure and is not without political significance; its analogue may be found in the international systems at present existing for meteorological observations. Heretofore international cooperation against disease has been confined to sudden outbreaks of the more virulent epidemic maladies. It must be the sincere hope of every philanthropist that the result of this organisation may be the complete annihilation of one of the most potent and widespread causes of disease in existence.

The dissemination of tuberculosis was naturally one of the subjects which engaged the attention of the Congress. It is now recognised that tuberculosis is an infectious disease, and therefore that it is preventable. One of the chief sources of infection is the sputa of consumptive patients. In this connection much has been done recently to check the habit of indiscriminate spitting in public places. At the present time in Glasgow, Manchester, Liverpool and some other towns, it is a penal offence to spit on the corporation tramcars, and the Glamorganshire County Council has made a bye-law to the effect that spitting on the floor of public carriages, churches or other public buildings is punishable by a fine not exceeding 5*l.*

Another point of interest brought to light by the Congress was the growth during recent years of provision for consumptive patients in sanatoria. This has occurred through new hospitals being built and old ones being enlarged. As a marked instance of the latter, the Mount Vernon Hospital at Hampstead may be quoted. Four years ago there was accommodation at this hospital for fifty patients; when the present building operations are complete there will be accommodation for two hundred and fifty. At the present time in the United Kingdom there are, however, only about 1000 beds for poor patients and about 1200 for paying patients.

The question of the compulsory notification of tuberculosis and the disinfection by the municipal authorities after deaths from tubercular disease was also discussed. The opinion seemed generally in favour of compulsory notification, which already exists in Norway. An interesting paper was read on the subject of dispensaries for consumptives, which have been founded in Belgium. They are supported by private societies with the aid of town councils. The patients receive food, coal, clothes, bedding, antiseptics, lodging disinfection every three months, and family washing every week.

Perhaps the most interesting item in the proceedings of the Congress was Prof. Koch's address upon the transmission of bovine tuberculosis to man. This authority maintains the thesis he enunciated in London last year, that the meat and milk of tuberculous cattle are very rarely, if ever, the sources of tuberculous infection to the human subject. In this connection Prof. Koch laid special emphasis on the fact that though for more than a year past he had received official reports of all tuberculous cases coming under the notice of the German hospitals and the professors of pathology at German universities, no undoubted case of primary tuberculous infection of the intestines had occurred. He also drew attention to the fact that most drastic measures would be required if the meat and milk of tuberculous cattle were condemned as food, and that such an action would cause a great increase in the price of these foods, which would be to the detriment of the community.

F. W. T.

ANTHROPOLOGY AND GOVERNMENT IN THE UGANDA PROTECTORATE.[1]

IF the population of British East Africa, or even of the Uganda Protectorate only, can furnish as many anthropological problems as that of the little corner of the country between the north-eastern horn of Lake Victoria Nyanza and Mount Elgon, it is quite time that a scientific collection of the facts were commenced. Mr. Hobley's "Ethnological Survey" deals only with a district about 120 miles long by 60 or 70 miles wide. He enumerates within this area four distinct races, or at least peoples of four stocks, beside a number of miscellaneous tribes whose racial connections are at present unknown. It is obvious that with such a wealth of material a work of 95 imperial octavo pages must simply be of a preliminary character.

The only stocks with which the author attempts to deal in detail are the Bantu Kavirondo, interesting as being "practically the most northerly representatives of the Bantu race," the Ja-luo, a Nilotic people, and the Nandi and allied tribes, conjectured to be a mixture of

[1] "Eastern Uganda: an Ethnological Survey." By C. W. Hobley, Assoc. M.Inst.C.E., Sub-commissioner Uganda Protectorate. Occasional Papers, No. 1. (Published by the Anthropological Institute of Great Britain and Ireland, 1902.) Price 10*s.*

Negroes of the Nile Valley and some Hamitic people. The information furnished was collected in the first instance for administrative purposes. It consequently relates chiefly to such matters as would come more directly under the notice of a British official in the early stages of the settlement of the country. Mr. Hobley has in regard to such matters been minute and careful in his inquiries. He has made an excellent beginning, though, as he himself says, "it would be presumptuous to suppose that [his] observations do more than touch the fringe of inquiry into the habits and customs of these interesting people." As examples of the painstaking manner in which he has collected his material, his plans of the Kavirondo and Nandi huts, and his figures, placed side by side, of the hoe (the principal agricultural implement of the continent) used by the Kavirondo and that used by the Nandi, may be referred to. By the courtesy of the Anthropological Institute we are enabled to reproduce these.

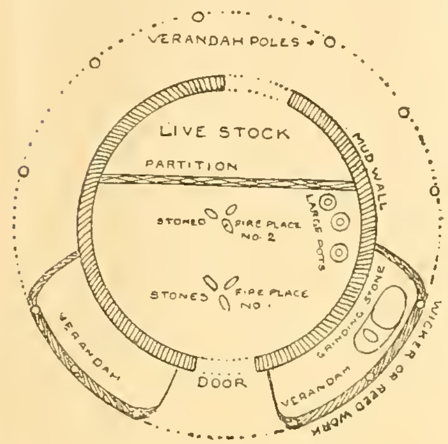

Fig. 1.—Plan of Kavirondo Hut.

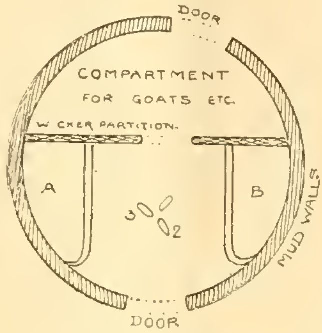

Fig. 2.—Plan of Nandi Hut.

The externals of native life and the outline of their customs, especially the customs relating to marriage and married life, are most fully treated. But there is evidently much detail still to be ascertained, and the underlying beliefs call for inquiry. The social organisation is hardly touched. Mr. Hobley's use of the words *clan* and *tribe* lacks precision. Both words seem to be used territorially; the clan is a local subdivision of the tribe, under a subordinate chief. By anthropologists the word *clan* is now generally used to indicate blood-relationship, actual or imputed. It should be kept strictly for this purpose and some other word found for a village settlement or other local subdivision the inhabitants of which may or may not be held to be blood-brothers. The important subject of religion, so intimately connected with social organisation, is almost a blank. The details concerning divination by the entrails of animals slain (in sacrifice?) and concerning the ceremonies in making peace, however, are interesting and valuable. These are matters likely to have come frequently under the sub-commissioner's eye. On the other hand, he is not likely to have suffered much from the medical practice of the Kavirondo. Hence his account of it is not very illuminating. The anthropologist who reads that the old women who are called in "put pebbles in a gourd and rattle them, and then advise certain remedies," will suspect that the pebbles are not only put into the gourd, but thrown out like dice, and that the practitioner divines from their fall, as among the more southerly Bantu, what is the matter and what remedies, if any, are to be prescribed. Probably Mr. Hobley has never witnessed the ceremony but writes from imperfect information. Useful plates of the Ja-luo are provided, and a plate of three Masai warriors. But nothing in the way of physical measurement has been attempted. Physical descriptions are vague, and evidence of race is chiefly made to rest on the deceptive basis of language. There is an excellent map of the district, showing the distribution of the various tribes. Vocabularies of several of the languages and grammatical observations are appended.

I have called attention to some of the deficiencies of this "Survey," not by any means for the purpose of finding fault, but in the hope that Mr. Hobley, who has commenced so well, will be induced to prosecute the work still further. Such investigations ought to have the most strenuous encouragement on the part of the administration, both for scientific purposes (to which no administration ought to be indifferent) and because everything that contributes to our knowledge of the people, their physical and mental capacities, their prejudices, customs and beliefs must make for good government. E. Sidney Hartland.

NOTES.

Prof. W. H. Holmes, head curator for anthropology of the National Museum, has been appointed chief of the United States Bureau of Ethnology at Washington in succession to the late Major J. W. Powell, the former director. Prof. Holmes is well known to anthropologists for his studies on the pottery and decorative art of the aborigines of America, and on the manufacture of stone implements, &c. He has also decided and advanced views on the arrangement of ethnological museums.

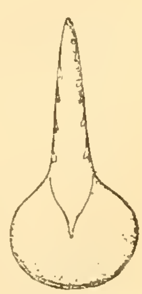

Fig. 4.—Nandi Hoe.

The Lancaster Town Council has decided to confer the honorary freedom of the borough upon Mr. James Mansergh, F.R.S., past president of the Institution of Civil Engineers, who is a native of the borough.

Last week the Bangor Eisteddfod Committee voted from its surplus a sum of 30*l.* to the University College of North Wales to assist in the development of the fisheries department.

In September Prof. White arranged for a fisheries exhibit in the arts and science section of the Eisteddfod, and partly owing to this as well as to the good work which the College has been doing in connection with the Welsh fisheries, the Committee decided to make the grant. The sum will be utilised in developing the fisheries collection at the College, which is in course of formation.

A RICH collection of Babylonian antiquities has been presented by the Sultan to Prof. Hilprecht, head of the archæological department of the University of Pennsylvania, in recognition of the services rendered by him to the Imperial Museum at Constantinople. Prof. Hilprecht has placed the collection in the University Museum.

A TELEGRAM from Kingstown, St. Vincent, published in the *Times*, says:—"The British botanists, Messrs. Powell, Quinton and Foster, spent an hour and a half on the summit of the Soufrière on October 28. The crater was then active, emitting steam and ashes. The new crater showed no signs of recent eruption. There was a slight eruption that night, and the disturbances continue, causing much excitement at Georgetown, where the tremors are continually felt."

MR. JOSEPH CLARK writes from Street, Somerset, to confirm Mr. Clayden's observations of recent remarkable sunsets (p. 659). On Friday, October 24, very brilliant colours were seen and particular notice was taken of the long time during which the clouds to the south-east retained a rosy tint. On Tuesday, October 28, there was a fine display of bright rose-colour on the eastward rolling clouds, an effect also noticed at Paris on the same evening.

WE regret to record the death, on October 23, of Mr. William Gunn, F.G.S. Mr. Gunn joined the staff of the Geological Survey in 1867 as assistant geologist, and attained the rank of district geologist in 1901. He was engaged during his long service in Durham and Northumberland, in the Scottish Highlands and latterly in Arran; and the results of his work appear for the most part in the maps and memoirs of the Geological Survey. His discovery of remnants of Secondary fossiliferous strata in a volcanic vent in Arran was brought before the Geological Society last year. Mr. Gunn had quite recently retired from the public service, having attained the age of sixty-five.

THE Thomson foundation gold medal of the Royal Geographical Society of Australasia, Queensland, will be awarded to the author of the best original paper (provided it be of sufficient merit) on each of the following subjects, the papers to be sent in by the dates named:—(1) The commercial development, expansion and potentialities of Australia—or, briefly put, the commerce of Australia (July 1, 1903); (2) the pastoral industry of Australia, past, present and probable future (July 1, 1904); (3) the geographical distribution of Australian minerals (July 1, 1905); (4) the agricultural industry of Australia (July 1, 1906). The competition is open to members and non-members of the Society alike, whether residing in Australasia or elsewhere.

SOME of the services which medical science has rendered to the State were referred to last week by Lord Roberts in an address delivered at the annual meeting for the distribution of the prizes gained during the past year by the students of the St. George's Hospital Medical School. Lord Roberts remarked that no section of the public was more deeply interested in the work and in the scientific researches of the medical profession than soldiers were, and that a deep debt of gratitude was due to those who, by their constant study, earnest inquiry and careful experiments, learned and taught how to heal the sick, to tend the wounded, to alleviate pain and suffering, to fight sickness and disease and to maintain health in camp and in quarters. A comparison of statistics as to the loss by sickness and disease in the Crimea and during the war in South Africa showed what a changed and improved condition of things prevailed now, changes and improvements which were largely due to the march of medical science. If great results were to be achieved, if success was to be won, there must be no slacking off in any pursuit or profession nowadays, least of all in the professions of medicine and surgery. Fresh fields in many directions remained to be explored, fresh developments to be observed and followed up, fresh results to be recorded.

IT was announced on the reopening of the House of Commons Committee dealing with the London electric railways that the Bill promoted by the London United Railways for a "tube" from Hammersmith to Piccadilly would be withdrawn (see NATURE, vol. lxvi. p. 296). This railway was intended to provide, with the Piccadilly and City and North-East London Railways, a through route from west to north-east, linking the tramway system of the London United Tramways with the City.

THE last link of the Pacific cable was completed at the end of last week, and it is hoped that it will very soon be opened for public traffic. The Pacific Cable Board does not, however, assume responsibility until thirty days after completion. The completion of this cable marks another step forward in cable enterprise. It is more than 8000 miles long, and is built up in five sections as follows:—Vancouver to Fanning Island (3653 miles), thence to Fiji (2181 miles), to Norfolk Island (1019 miles), and then to Moreton Bay, Queensland (906 miles) and New Zealand (513 miles). The cable has been laid by the Telegraph Construction and Maintenance Company at a contract price of rather under 2,000,000*l*., and in less than two years; it is comforting to reflect that England still stands preeminent in this branch of electrical engineering. The completion of the line was made the occasion of the exchange of congratulatory messages between Mr. Chamberlain and the different governors of interested colonies. Among the most interesting of these are two sent by Sir Sandford Fleming to Lord Minto; these completely circled the world, one, in an easterly direction, in 10h. 25m., and the other, going westerly, in thirteen hours and a half. We have still some progress to make before we are able with Puck to "put a girdle round about the earth in forty minutes."

THE presidential address delivered by Mr. J. C. Hawkshaw before the Institution of Civil Engineers on Tuesday covered a wide range of subjects, among them being docks, timber and forestry, canals, means of traffic and transport, the world's supply of fuel, water-power available for industrial uses, and the value of purely scientific studies to the engineer. Upon the latter point, Mr. Hawkshaw made the following remarks at the end of his address:—"Wherever our work may take us we have always something at hand to observe if we give some thought to geology or some branch of biology. Geology calls to its aid all sciences; biology, even botany, is not one, but many sciences. Every science and every question of science is first a matter of fact. Facts observed which seem trivial in themselves may lead to much. Reaumur it was who first suggested that wood-fibre should be used for making paper. He was led to do so from observing the structure of wasps' nests. Out of that observed fact a great industry has grown which threatens to tax the forest supplies of the world. If we accept the view of M. Maurice Levy that from the study of celestial mechanics was derived later general mechanics, then all our progress has come from the study of what was useless at the time it was studied. We might well, I think, increase the number of optional subjects for our examinations. There is no branch of natural knowledge which may not be studied with advantage by an engineer as a change

and relaxation in the round of daily work, and as a training of his power of observation. For after all is said, it is only by observing that we can know."

AT a meeting of the Society of Engineers held on Monday, November 3, a paper was read on "The Effect of Segregation on the Strength of Steel Rails" by Mr. Thomas Andrews, F.R.S. In the course of the paper, the nature and primary causes of segregation in steel rails were described, and the influences of local transverse and longitudinal segregation on the loss of strength in such rails was demonstrated. Microscopic studies have specially indicated some of the latent sources of weakness which occur in segregated steel rails leading to their premature fracture in main-line service. Numerous chemical, physical and high-power microscopic examinations have been made on a considerable number of rails in which local segregation of some of the chemical constituents had been detected, and the author's investigations have demonstrated that local segregation of this nature distinctly reduces the general physical strength and main-line endurance of steel rails in which segregation exists. Reference was also made to the importance, in the interests of public safety, of detecting and eliminating from service, so far as practicable, rails having a tendency to segregated chemical composition.

SIR CHARLES TODD, Government Astronomer of South Australia, has published his valuable report on the rainfall of the colony for the year 1899, showing the monthly and yearly amounts and the averages for previous years at a large number of stations. The report is illustrated by maps showing clearly at a glance the rainfall characteristics of the year. Very few stations registered their average amount, principally owing to the failure of the rains during the latter part of the winter (July and August) and in October and December. The report contains a table showing the yearly rainfall at Adelaide for sixty-one years, 1839 to 1899, and the years when the fall was above or below the normal amount (20·85 inches).

WE have received from Dr. H. Hergesell, president of the International Aëronautical Committee, a preliminary report of the balloon ascents made during the three months April to June last. Austro-Hungary, France, Germany and Russia took part in the investigation, and twenty-one ascents were made. The following were the greatest altitudes attained by the unmanned balloons:—April 3, Itteville (near Paris), 14,260 metres, minimum temperature $-60°·7$ C., temperature at starting 7°. May 1, Berlin, 19,564 m., lowest reading $-58°·5$, on ground 6°·8. June 5, Berlin, 16,750 m., $-58°·2$, 18°·4. Vienna, 10,480 m., $-62°·8$, 15°. The greatest heights attained by manned balloons were in ascents from Berlin:—

April, 5403 m.,	temperature	$-19°·4$,	at starting	6°·6
May, 5510 m.,	,,	$-30°·5$,	,,	6°·2
June, 5936 m.,	,,	$-18°·0$,	,,	20°·9

In the latter case the observers were Dr. Berson, and Prof. Palazzo, of Rome. On each occasion Mr. Rotch sent up kites from his observatory at Blue Hill, near Boston, U.S. On the days of the ascents, areas of low barometric pressure lay over western Europe in April and May, and an area of high barometric pressure in June.

IN his report for the year 1900–1, the first volume of which is now to hand, the chief of the U.S. Weather Bureau directs attention to an important extension of the forecast work of the Bureau made during the year with which the report is concerned. At the end of 1900 was begun, by an arrangement with our own Meteorological Office, the transmission by cable from London to Washington of meteorological reports from certain observing stations in the British Isles and on the continent of Europe, and from Ponta Delgada, Azores. These reports, with observations from Nassau, Bermuda and Turks Island, have been regularly published on the daily weather maps issued at Washington, Baltimore, Philadelphia, New York and Boston, together with forecasts of the force and direction of the wind and the state of the weather for the first three days out of steamers bound east from American ports. Arrangements were also made with Portugal towards the end of 1900 for the receipt at Washington of reports from the meteorological observatory at Horta, in the Azores. Observations are now regularly transmitted by cable from this place, and have proved of much value in the work of forecasting the movements of storms on the Atlantic Ocean.

THE Imperial Department of Agriculture for the West Indies has issued a Report on certain economic experiments conducted in connection with the Antigua Botanic Station during the period from May, 1901, to April, 1902. Considerable variation was shown in the crop results, to a great extent attributable to the abnormally wet season, the year's rainfall amounting to 75·46 in., the total for the preceding year being 42·67 in. February was the only dry month. The experiments have for their objects the improvement of local food products, the introduction of new crops, and the placing on record of interesting facts bearing on insect and fungoid attacks, climatic conditions, &c. An investigation of the black-spot disease of pine-apples and of their rotting during transit to Europe has led to the conclusion that the former is due to injury, during the period of growth, from the attacks of a Penicillium, and the latter to injury, after cutting, from the attacks of *Trichosphaeria Sacchari* (rind fungus) and a species of Diplodia.

PROF. J. SCHNEIDER contributes an interesting paper, on the diurnal movements of the atmosphere at Hamburg, to the September number of the *Meteorologische Zeitschrift*. The wind observations published in the "Deutsche Meteorologische Jahrbuch" for the years 1887 to 1896 are dealt with by resolving into components in west-east and south-north directions, and the diagram of hourly movement shows that the daily curve is entirely closed, its form being egg-shaped, with the narrow end pointing north-east, and its total perimeter about 45 kilometres.

DR. A. SPRUNG describes a number of photographs of halos and parhelia, taken by him at Potsdam on March 23, in the August issue of the *Meteorologische Zeitschrift*. One of the photographs is reproduced. The phenomena are of special interest from the fact that they include both parhelia and the rare large halo, and that the dark spaces are indicated in the photographs. Measurements of the plates give the following mean results, which are compared with the means of direct measurements made by different observers:—

	Mean radius of small ring.	Distance of parhelia.	Mean radius of large ring.
Photograph ...	22° 22′	23° 2′	46° 25′
Observers ...	22° 23′	24° 24′	46° 15′

THE problem of the representation by a finite number of parametric formulæ in two variables of the neighbourhood of a singular point of an algebraic surface was first solved in 1892 by Gustav Kobb, but his solution received criticism at the hands of Beppo Levi in 1897. Mr. C. W. M. Black, writing in the *Proceedings* of the American Academy of Arts and Sciences, now gives a new investigation of the problem, which is claimed not only to supply the deficiencies in Kobb's reasoning, but also to extend the discussion from the case of an algebraic surface to the more general case of any analytic surface whatever.

MR. C. H. HINTON has published, in the *Bulletin* of the Philosophical Society of Washington, a paper on the "Recognition of the Fourth Dimension." In it the author examines

what would be the general character of the motions of bodies in space of four dimensions. The most interesting feature of this line of inquiry is the possibility which is pointed out of constructing representations of the phenomena of electromagnetism by means of vortex motions in four-dimensional space. Thus a vortex with a surface as its axis affords a geometric image of a closed circuit, and there are rotations which by their polarity afford a possible definition of static electricity. Has it occurred to the author that the property that electricity which is free to move in a conductor assumes a superficial distribution may enable us to form a conception of matter in four-dimensional space assuming a three-dimensional distribution?

THE work done by Prof. Barrett and Messrs. W. Brown and R. Hadfield on the properties of alloys of iron is of very high importance to all engineers, whether electrical or civil. The third part of a paper on the subject is published in the *Scientific Transactions* of the Royal Dublin Society for September; the two first parts were published in 1899. In the present section, non-magnetic alloys of iron and alloys more magnetic than best Swedish charcoal iron are considered. Manganese added to iron to the extent of about 13 per cent. gives an alloy which is practically non-magnetic; a still more remarkable effect is seen with manganese-nickel-steels; magnetic alloys of iron with manganese or nickel can be made non-magnetic by adding a suitable amount of the other metal. There is possibly a great future for such alloys in shipbuilding. The alloys more magnetic than the best commercial iron are made with nickel, silicon and aluminium. The authors suggest that an iron alloy containing silicon and aluminium will very probably prove to be the best material to use for transformers. The great value of this work is obvious, and we should like to be able to deal with it more fully; fortunately, the results are easily accessible, as a paper covering practically the same ground as all three of the Dublin papers was read by the authors before the Institution of Electrical Engineers last February (*Journal* I.E.E., vol. xxxi. p. 674).

THE Health Department of the City of London has had a number of samples of ice-creams bacteriologically examined. A large proportion of the samples was found to be unsatisfactory; in several micro-organisms were very numerous, while in some virulent organisms of the *Bacillus coli* type were present; one contained pyogenic organisms and produced abscesses in guinea-pigs, and another contained an anaërobic organism, perhaps the bacillus of malignant œdema. Many of the ice-creams from which samples were examined had set up gastro-enteritis in boys employed by the Post Office. The London County Council (General Powers) Act, 1902, which came into force on November 1, contains clauses relating to ice-creams, regulating their manufacture, &c., and notices in Italian have been printed for distribution among the vendors.

WITH the publication of the October number (vol. ii. No. 4), the *Journal of Hygiene* completes its second volume and its second year of issue. Messrs. Wright and Windsor contribute a paper upon the bactericidal effect of human blood *in vitro*, and find that whereas human blood-serum has a powerful bactericidal action upon the typhoid bacillus and cholera vibrio, it is without action upon the *M. pyogenes*, *B. pestis* and *M. melitensis*. Dr. Haldane details the results of a lengthy experimental investigation upon the air of factories and workshops, Prof. Tunnicliffe discusses the digestibility of the various albuminous constituents of human milk and its substitutes, and Dr. Ritchie concludes his survey of the current theories regarding immunity.

PIOUSLY minded people have a tendency to accept as ancient anything which pretends to be a monument of Biblical history; as a consequence of this trait, Jewish shekels and half-shekels have been forged and even invented to supply the demand. An interesting exposure of these frauds is given by Mr. G. F. Hill in the *Reliquary and Illustrated Archaeologist* for October. There are other illustrated papers in this journal dealing with ecclesiastical architecture and stone-carving.

APART from the superstition bound up with the use of native medicinal remedies of the North American Indians, it is probable that their knowledge of herbs is much more extensive than that of the white man. Mr. V. K. Cheshunt, who has endeavoured to elicit from the Indians of Mendocino County, California, trustworthy information respecting the uses to which they put various indigenous plants, attributes our knowledge of *Cascara sagrada* to these tribes and suggests that other plants, such as Ceanothus, Croton and Eriogonum, would well repay investigation. The diet of the inland tribes is peculiar, as they regard young clover shoots as a delicacy, and make use of acorns and the variety of horsechestnut known as "buckeye" for making a porridge or baking into bread. The method adopted is to pound up the seeds into very fine flour and wash out the tannin and other stringent ingredients with water. A porridge or thick soup is formed by boiling the flour, while a favourite recipe for making bread consists in mixing the dough with red clay. The product is a heavy, black, cheese-like substance, in which the clay probably absorbs the oil and converts the last trace of tannin into a more digestible form. Another curious custom previously in vogue was the use of poisonous plants, soap root and turkey mullein, which were thrown into streams to poison the fish. These were then caught and eaten without any deleterious consequences.

NEW fields for research are continually opening up; the last illustration of this is the discovery by Prof. G. Elliot Smith that it is possible to map the convolutions of the brains of non-mummified ancient Egyptians. The brain is naturally preserved in the vast majority of the bodies in Egyptian cemeteries from predynastic to recent Coptic, the favourable conditions being burial in dry soil and removal from all direct access to the air. Prof. Elliot Smith gives an illustrated preliminary paper on the natural preservation of the brain in the ancient Egyptians in the *Journal of Anatomy and Physiology* (vol. xxxvi. p. 375). In a memoir, which will be published in a short time, he intends to give a full account of the structure of the brain in the predynastic and protodynastic Egyptians.

IN the Report of the Madras Museum for 1901–1902, the appointment of the director, Mr. E. Thurston, as superintendent of the Ethnographic Survey of Madras is an announcement which will be read with satisfaction by all anthropologists. The papers on the hill and other primitive Madras tribes already published by Mr. Thurston have placed him in the first rank among the students of anthropology and ethnography, and he will now doubtless have fuller opportunities of pursuing these subjects. Anthropological studies have, it appears, an amusing, if not a somewhat embarrassing, aspect in Madras. When on tour in one district, for example, Mr. Thurston was reputed to be collecting for the Victoria Memorial, inoculating for the plague and recruiting for the Boer war, the measurements that he took giving rise to the idea that he was an army tailor! The ethnographic reports of native assistants are, moreover, not exactly what they should be, as witness the following:—"They know how to make fire; *i.e.*, by friction of wood as well as stone, &c. They take a triangular cut of stone and one flat oblong size flat. They hit one another with the maintenance of coir or copper, then fire sets immediately and also by rubbing the two barks frequently with each other they make fire."

THE account of the "Plants of Chatham Island," which formed the subject of an address by Mr. L. Cockayne to the

members of the New Zealand Institute, not only possesses the interest which attaches to the impressions obtained by a personal visit, but is additionally so as it is still possible to trace the original vegetation and study the changes which are taking place owing to the introduction of animals and foreign plants. A remarkable and regrettable instance of the latter is the almost complete annihilation of the plant well named *Myosotidium nobile*, which originally lined the shore just above high-water mark. The sheep feed on the leaves and the pigs grub up the rhizomes, and now this plant is limited to quite a few localities. A striking feature of the island is the large Te Whanga lagoon, which occupies about one-third of the island. This, however, is not so important botanically as the swamps, which represent a transition stage from lagoon or lake to drier localities which rapidly become forest lands. Not the least curious feature, and one which has been noted but not satisfactorily explained in other countries, is the occurrence of plants with xerophytic characters growing in the swamps. Such an one is a peculiar Restiaceous plant, *Leptocarpus simplex*, which grows in the wettest parts, while another is *Olearia traversii*, which, however, may be taken as an indication that the swamp is passing into a dry condition.

Messrs. James Swift and Son have sent to us, for trial, one of their compound microscopes of recent type, fitted with their newly patented "Ariston" fine-adjustment. The essence of this is the setting of the micrometer-screw and its milled head upon a closed tube, which, like a jacket, surrounds the pillar. By the attachment to the head of this jacket of a couple of levers, upon the upper part of which the screw reacts by means of a fine point, there is assured a successful elimination of the troublesome side-movement resulting from a bending of the metal composing the limb when the fine-adjustment is subjected to pressure. In thus ensuring to the operator the comfort of absolute rigidity, the conditions employed give with a coarse screw a slow rate of speed and a very delicate result. The apparatus is entirely satisfactory, and can be fitted to certain of Messrs. Swift's microscopes at small cost. It is worthy their newer mechanical stage, their ruled "finder," and the devices, simple but effectual, which they have from time to time introduced into the construction of their instruments for compensation in wear and tear. In these and other similar matters of recent years, Messrs. Swift have shown themselves constantly on the alert for improvement. In the excellence of their $\frac{1}{12}$-in. homogeneous oil immersion, they have produced an English-made lens of first-rate capacity which is a marvel of cheapness; and it must not be forgotten that in the early days of the modern student's microscope they were the first to introduce the Jackson type of stand, just as we believe it was the Englishman Collins who similarly first produced the iris-diaphragm, which, like it, was a triumph for British manufacture.

The Report of the U.S. National Museum, under the direction of the Smithsonian Institution, for the year ending June 30, 1900, is, as usual, remarkable for the many interesting papers it contains and the wealth of beautifully executed illustrations which accompany them. The first part of the volume contains the report of the assistant secretary, and includes sections contributed by the head curators of the departments of anthropology, biology and geology. Part ii. makes up nearly 600 of the 738 pages to which the report runs; it contains seven contributions, some of which may fairly be called monographs. Mr. W. H. Holmes, head of the anthropological department of the museum, describes his anthropological studies in California, his contribution being illustrated with fifty excellent plates. The pictures of the baskets made by the Tulare Indians and the scenes showing incidents in their everyday life are particularly fine. An exhaustive study of aboriginal American harpoons, in which they are treated as a study in ethnic distribution and invention, is by Dr. O. T. Mason, the curator of the division of ethnology. Nineteen plates and nearly a hundred figures accompany this article. The Commissioner of the Imperial Maritime Customs Service of China, Mr. A. E. Hippisley, gives a sketch of the history, with twenty-one plates, of ceramic art in China, and supplies a catalogue of the Hippisley collection of Chinese porcelains. The remaining papers are, "Contributions to the History of Musical Scales," by Mr. C. K. Wead, of the U.S. Patent Office; "A Collection of Hopi Ceremonial Pigments," by Mr. W. Hough; a "Descriptive Catalogue of the Collections of Gems in the U.S. National Museum," by Mr. Wirt Tassin; and a catalogue of the meteorite collection, by the same author.

Messrs. C. Griffin and Co., Ltd., have recently published a ninth edition, revised and enlarged, of Prof. A. Jamieson's "Elementary Manual on Steam and the Steam Engine." From the same publishers we have received the fifth edition of Prof. Jamieson's "Elementary Manual of Applied Mechanics," which has also been enlarged.

A number of stereoscopic slides of scientific interest have been prepared by Messrs. Erdmann and Schanz, Bedford Hill, Balham, London, S.W. Among the subjects represented are type studies from India and Ceylon, hoar-frost scenes and wild animals. A compact and effective stereoscope with aluminium hood is supplied by the same firm.

Two more volumes belonging to the *Scientia* series, published in Paris by M. C. Naud, have been issued. One, No. 14 of the biological series, by Prof. A. Imbert, of the University of Montpellier, is entitled "Mode de Fonctionnement économique de l'Organisme." The other, No. 20 of the physico-mathematical series, is by M. H. Laurent, "Sur les principes fondamentaux de la Théorie des Nombres et de la Géometrie." Each volume is a short monograph giving the present state of knowledge of the subject surveyed.

The thirty-fourth volume of the *Proceedings* of the London Mathematical Society, which has now been published, contains the papers communicated to, or read before, the Society from March, 1901, to April, 1902, and some of the contributions included in the publication are of high mathematical interest. We have also received the second volume of "Mathematical Questions and Solutions from the *Educational Times*." The collection is edited by Miss Constance Marks, and is supplemented by papers and solutions which have not hitherto been published.

The volume containing the physical papers of the late Prof. Henry A. Rowland, the preparation of which for publication was announced in April of this year, is now nearly ready for distribution to its subscribers. It has been edited under the direction of a committee, consisting of President Remsen, Prof. Welch and Prof. Ames, who have made every effort to present to the world, in a suitable form, this memorial of their colleague. The price of the volume will be one guinea per copy for orders sent in advance of publication, after which the price will be increased. Orders may be sent to Prof. Joseph S. Ames, Johns Hopkins University, Baltimore, Maryland.

A brilliant address on "The Rise of the Experimental Method in Oxford" was delivered by Prof. Clifford Allbutt before the Oxford University Scientific Club last May, as the ninth Robert Boyle lecture. An abstract of the address was given in these columns on May 22 (p. 90), and readers of it could not fail to be struck by the richness and charm of the style in which Prof. Allbutt dealt with his subject. The complete discourse, which has now been published by Mr.

Henry Frowde at the price of one shilling net, should be obtained by everyone interested in the history of science.

IN a communication published in the May number of the *Transactions* of the American Microscopical Society, Messrs. Whipple and Parker discuss the connection between the amounts of oxygen and carbonic acid dissolved in natural waters and the occurrence in these of microscopic organisms. It has long been known that exhaustion of nitrates takes place in ground water supporting a vigorous growth of algæ, and it has been assumed that nitrates are the fundamental factor in the development of these. Nitrates are indeed important, but the inadequacy of this explanation became manifest when it was observed that some water, comparatively poor in nitrates, at times supported large growths of algæ. The authors point out the apparent importance of carbonic acid, and express the opinion that the algæ are influenced by it more than by the nitrates. The study of the number of organisms in water at different depths has given some interesting results. Water taken from Lake Cochituate was found to contain the following numbers of Mallomonas per cubic centimetre :—

Depth in feet ...	0	10	30	30	40	50
No. of organisms	0	0	1454	548	112	88

At the surface and throughout the circulating water above the thermocline, oxygen was abundant, but carbonic acid was absent. Near the bottom of the lake there was carbonic acid, but no oxygen, whereas just below the thermocline both gases were present, and as Mallomonas is a chlorophyll-bearing organism it found there conditions favourable for its development.

THE additions to the Zoological Society's Gardens during the past week include two Kusimanses (*Crossarchus obscurus*), a White-crested Tiger Bittern (*Tigrisoma leucolophum*), a Great-billed Touracou (*Turacus macrorhynchus*), a Sharpe's Wood Owl (*Syrnium nuchale*) from West Africa, presented by Mrs. Hurst; a Mute Swan (*Cygnus olor*), a White-fronted Goose (*Anser albifrons*), four Widgeon (*Mareca penelope*), two Pintails (*Dafila acuta*), four Pochards (*Fuligula ferina*), six Common Ducks (*Anas boscas*) European, two Black Swans (*Cygnus atratus*) from Australia, presented by Mr. W. N. McMillan; a Persian Gazelle (*Gazella subgutturosa*) from Central Asia, presented by Mr. B. T. Ffinch; two Emperor Boas (*Boa imperator*) from Central America, presented by Dr. Hans Gadow, F.R.S.; a Thick-tailed Opossum (*Didelphys crassicaudatus*) from La Plata, a Blue-fronted Amazon (*Chrysotis oestiva*) from South America, deposited.

OUR ASTRONOMICAL COLUMN.

VARIATION IN MAGNITUDE OF α ORIONIS.—Mr. D. E. Packer, of Birmingham, has recorded, in a letter to No. 1961 of the *English Mechanic*, the observation that α Orionis is increasing in brightness. Although a known variable, its general variations for the past thirty years have been so minute as to attract no particular attention, but Mr. Packer says that, on the night of October 15, the star was distinctly brighter than Capella and only slightly less bright than Sirius.

Herschel recorded very marked variations in the magnitude of this star between 1836 and 1840, and Sir W. Huggins noticed variations in its spectrum during a second period of variability, 1849–1852. Mr. J. E. Gore confirms Mr. Packer's observations.

THE NEBULA AROUND NOVA PERSEI.—Prof. C. D. Perrine publishes, in the *Bulletin* (23) of the Lick Observatory, several reproductions, and the measures, of the excellent photographs of the nebula around Nova Persei which were obtained with the Crossley reflector, and he also discusses the striking changes observed in the condensations of the nebula.

From measurements of the negatives obtained on March 29, 1901, and January 10–11, 1902, respectively, it appears that the inner ring of nebulosity is expanding radially, at an average rate of 1″·4 per day, whilst the outer ring is similarly expanding 2″·8 per day. These measurements of the inner ring would carry it back to the Nova on February 8, 1901, whilst the outer ring is similarly carried back on February 16–17; both the plates give the same dates. This does not imply the prior formation of the inner ring, for, considering the uncertainties of measurement, Perrine suggests their contemporary origin.

Many suggestions have been made to explain the apparent velocities of parts of the nebula, the two chief explanations being the transition of material particles, and the propagation of a wave of light through, and reflection from, the fine particles of matter making up the nebula. The former seems unlikely, because the movement contains a large tangential factor, whilst the latter theory would have to presume largely variant velocities of the light waves, a presumption which is inconsistent with our present knowledge of light. In order to test the "reflection" theory, Prof. Perrine introduced a double-image prism between the plane mirror of the Crossley reflector and the photographic film, and found that the light was not polarised, *i.e.* the two images were of equal intensity. On polarising the light from α Lyræ and treating it in the same manner, he found that the mirrors of the instrument had practically no effect on polarised light.

The final result points to the existence of little or no polarisation in the light from condensation D, and, with less certainty, in that from condensation A, and therefore refutes the reflection theory.

CORONAL DISTURBANCE AND SUN-SPOTS.—In No. 98 of *Popular Astronomy*, Prof. Perrine demonstrates the close connection between the coronal disturbance, photographed at Sumatra during the total eclipse of 1901, and the group of sun-spots and extensive faculæ which came round the limb of the sun on May 19.

From photographs of the solar disc obtained at Dehra-Dun, India, between May 18 and 28, inclusive—of which copies were kindly supplied to Prof. Perrine by the Astronomer Royal—it is seen that a fairly large group of spots and faculæ came round the limb on May 19, and that at the time of the eclipse this group would be very near to the limb. The position angle of the spot, as projected on to the limb, was 60°·2, whilst that of the apex of the coronal disturbance was 60°·0, and during the eleven days under observation this was the only group of spots photographed. This shows conclusively that the spot and the coronal disturbance were in the same line of sight, and further reductions have shown the probability that the origin of the coronal disturbance was also near to the limb at the time. The long, thread-like prominence seen projected almost tangentially from the sun's limb during the eclipse appears to have emanated from the same group of spots and faculæ, so that, in this case at least, all these phenomena appear to have had a common origin.

This aggregation of related phenomena seemed to point to the possibility of the existence of a great disturbance in the solar atmosphere on this date, and a further investigation was made in order to discover if any measurable displacement of the coronal masses took place in the disturbed region. The photographs compared were taken at an interval of five minutes, and no measurable displacement can, with certainty, be traced thereon; from this we may conclude that the velocity across the line of sight was less than twenty miles per second. A comparison between the photographs obtained at Mauritius and Sumatra, respectively, with an interval of one-and-a-half hours, would probably decide this question of movement.

THE VARIABLE STAR 13, 1902, LYRÆ.—Further observations of this Algol variable have given the following results :—

Approximate position for 1900, 19h. 12m. 31s. +32° 14′·8. Range of magnitudes, 10·98 to about 12·8. Period, 3d. 14h. 22m. 23s.·5.

The Variable Star Committee of the Astronomische Gesellschaft has assigned to this star the designation R.V. Lyræ (*Astronomische Nachrichten*, No. 3821).

NEW VARIABLE STAR, 15, 1902, DELPHINI.—Dr. Anderson, of Edinburgh, has communicated to No. 3821 of the *Astronomische Nachrichten* his observation that a star, not mentioned in the B.D., but having the approximate position R.A. = 20h. 34m. 43s., Dec. = + 11° 21′·5 (1855·0), has proved to be a variable.

Assigning the magnitudes 9·5, 9·7 and 11·2 to B.D. + 11°·4353, B.D. + 11°·4358, and a star having the approximate position

20h. 34m. 37s. + 11° 18'·5, respectively, the following magnitudes have been observed for the newly discovered variable :—

Date, 1902.		Magnitude.

EDUCATION AT THE BRITISH ASSOCIATION.

THOUGH the youngest offspring of the British Association, the Section of Educational Science has developed so rapidly that its growth in strength and influence is being watched with interest not unmixed with anxiety by several of the older sections. Most of the meetings devoted to the discussion of educational topics were largely attended this year, and all of them have been reported in detail, thus showing that science in education and education in science appeal to a wide public. The Section provides a platform on which it is possible, not only to state the place science should occupy in the curricula of school and college, but also to describe the character of the instruction which should be given, and to construct an organic educational science out of the disjointed body of opinion. It is easy to see that, rightly directed, the work of the Section may have an important influence in determining lines of progress in education ; and the success so far achieved justifies faith in the promise of the future.

One characteristic of the proceedings of the Section is especially noteworthy. Instead of accepting a variety of papers on diverse disconnected subjects, each meeting has been devoted to the discussion of a specific matter introduced by one or two papers. Attention has thus been concentrated upon definite points, and it has been possible to obtain the expression of competent opinion around them. Imperfections of scope and method have been pointed out, difficulties described and reforms advocated with a breadth of view and maturity of experience which command the attention of the educational world.

As an instance of the effect of the work of the Section, mention may be made of the discussion on the scope and teaching of elementary mathematics, opened last year by Prof. Perry, which led to the appointment of a committee with Prof. Forsyth as chairman. In the report presented by this committee, several desirable reforms were indicated, all of them of a kind capable of adoption by teachers and examiners. The committee considers that different methods of teaching mathematics might be adopted for different classes of students, and corresponding types of examination should be used. Emphasis is laid upon the recommendation that the teaching of demonstrative geometry should be preceded by the teaching of practical and experimental geometry, together with a considerable amount of accurate drawing and measurement. In demonstrative geometry, no single book should be placed in a position of authority, nor should there be a single syllabus in control of all examinations. It is recommended that some association of arithmetic and algebra with geometry is desirable in all cases where this may be found possible. Examining bodies are advised that no candidate should be allowed to pass unless he gives evidence of some power to deal with questions not included in the text-book adopted. With regard to arithmetic and algebra, regret is expressed that the decimal system of weights and measures has not been adopted in this country. Graphical methods should be used wherever possible, and tables of simple functions should be introduced as soon as the student is capable of understanding the general nature of the functions tabulated.

In opening the discussion on points arising from this report, Mr. A. W. Siddons described the recommendations of the Mathematical Association Committee, of which he is honorary secretary. Like the British Association Committee, that of the Mathematical Association recommends that a first introduction to geometry, and to each new branch of geometry, should be experimental with the use of instruments and numerical measurements and calculations. So far as deductive geometry is concerned, Mr. Siddons pointed out that there seem to be four alternatives :—(1) To have no one syllabus placed in the position of authority; (2) to replace Euclid by *one* standard syllabus; (3) to modify Euclid by omission and readjustment ; (4) to retain Euclid in its present form.

The Mathematical Association Committee has recommended the adoption of a modified Euclid ; it is considered that the time is not yet ripe for the proposal of a standard to be adopted finally in place of Euclid. The modifications proposed include :—(1) The omission of some propositions which do not help on the course or which should be regarded as axiomatic ; (2) improved methods of proving other propositions, including the use of hypothetical constructions ; (3) the addition of a few propositions ; (4) the adoption of Playfair's axiom and the "limit" definition of a tangent ; (5) the use of angles greater than two right angles ; (6) that the exact treatment of incommensurables be regarded as a branch of higher mathematics.

The discussion upon the two reports was distinguished this year by the fact that mathematical masters from several public and other large schools were present and took part in it. It is evident from the opinions expressed that reforms in the directions advocated by the two committees would be welcomed by many teachers.

Mathematical ideas can be obtained by means of Froebel's boxes of geometrical solids and simple plane figures, but the school work after the kindergarten is not usually conducted on the same sound and systematic plan. An address on the subjects to be taught as science in schools and the order in which they should be taken, given by Dr. C. W. Kimmins, indicated desirable directions of study. Dr. Kimmins pointed out that the great reforms which have taken place in recent years in the teaching of science in schools have been due in large measure to the British Association report on the teaching of chemistry. Similar reports are needed on the teaching of other subjects suitable for instruction in schools, and it is hoped that the committee appointed on the teaching of botany will be of value in this connection.

Dr. Kimmins suggested that the interval between the kindergarten (pupils five to eight years of age) and the experimental science course should be utilised for suitable nature-study teaching. During this interval, thorough instruction should be given in practical mathematics, including the mensuration which is generally taken as part of the experimental science course. This should be given in the time devoted to mathematics, not science. Finally, it was considered that the subjects requiring special attention are the teaching of natural history and botany, and the correlation of science and art teaching.

When experimental science is introduced into schools, the best course of practical instruction to follow is one based upon heuristic principles, such as that which has been introduced into Irish national schools. Mr. W. Mayhowe Heller, who has organised the work, described the methods and results of the scheme. The Commissioners of National Education, in taking steps to introduce practical instruction into their schools, are attempting to do the work accomplished in the towns of England and Scotland by local educational enterprise. In elementary science, the typical course for boys and girls is based on the 1889 recommendation of the British Association Committee. Teachers attending training courses have to perform all experiments of the course themselves. Free equipment grants of apparatus for manual instruction and elementary science are given to necessitous schools. Very few schools at present have laboratories, but at the same time a great deal of individual experimenting can be accomplished. Object lessons are allowed as a substitute for a systematic course of instruction in experimental science, but these must attempt to achieve the same results as the science lesson, viz. accurate habits in observation, work, description and reasoning. Practical instruction of this kind is of the highest importance to Ireland ; for upon its successful introduction into the national schools depends the future of technical instruction.

The position of science in Irish intermediate schools was brought before the Section in two papers, one by Mr. R. M. Jones, head-master of the Royal Academical Institution, and another by Mr. T. P. Gill, secretary of the Department of Agriculture and Technical Instruction. Mr. Jones gave a survey of the working of the new scheme of intermediate education and indicated the probable tendency of developments. Practical work in physics and chemistry has been introduced into intermediate schools, the scheme followed being that of the Department of Agriculture and Technical Instruction. The result is that laboratories in which simple measurements and weighings can be conveniently carried on have been provided in many

schools, and the work done in them is of a most inspiring character both to teacher and pupil.

The science programme for the Irish intermediate or secondary schools was dealt with by Mr. Gill, who though by training and inclination a humanist, expressed his complete satisfaction with the aims and scope of the scheme. The programme was introduced for three reasons, which Mr. Gill expressed,as follows:—

"First, because we believe that science has a part as well as letters in the science of general education—(remember, I am speaking now only of the science part of the programme, and only of the secondary schools)—and, secondly, because the teaching of experimental science according to this programme involves a method now commonly called the heuristic method, which we believe has a great educational value and may be applied to the advantage of the study of other subjects as well as science. The third reason is the special value of science in connection with technical instruction."

Mr. Gill confessed that in admitting the claim of science in general education, and standing as its champion, he did so as a convert, and one who has been brought to that realisation of the power and value of science which is forced upon every modern man. "Scientific physics," he remarked, "which have now their recognised place in public instruction, are admittedly no more difficult to learn or to teach than Latin or Greek, and in our Irish public schools at the present time I venture to say Latin and Greek are not so well taught as our experimental science, with all the great drawbacks and the difficulties which have beset us in the endeavour to provide teaching power. The secondary school which has to do with the future leaders, the industrial and intellectual leaders of the country, would hardly be true to its function as a preserver of the equipoise of general knowledge, would hardly be a living institution informed by the spirit of the age, if it failed to take notice in its curriculum of the place science occupies to-day in the mental and material life of society."

Dr. W. J. M. Starkie, Resident Commissioner of National Education in Ireland, created a sensation among Irish educationists by a paper in which he criticised the recent reforms of primary and secondary education, undertaken with a view to their coordination. He condemned the managerial control of national schools in Ireland, and pleaded for that which every civilised country in Europe has long since attained—a single local authority for education outside of technical schools and universities. Nothing can be done, however, until educated and independent laymen come forward in sufficient numbers to make their influence felt on such authorities.

As regards English schools, Dr. J. H. Gladstone read the report of the committee on the teaching of science subjects in elementary schools; but the changes which have been caused by the introduction of the Block grant in place of the former examination grants have made it difficult to arrive at definite information as to the number of pupils receiving instruction in science. It is felt that the time has now arrived for a general survey of the progress made since the committee was appointed in 1879, and such a statement will, it is hoped, be presented to the Association next year.

Before any subject can be taught with success, the health of the pupil and the training of the teacher have to be considered. A preliminary report of the committee on the conditions of health essential to the carrying on of the work of instruction in schools was presented by Prof. C. S. Sherrington, F.R.S. Attention has so far been directed to the following points:—The periods of day appropriate for different studies, the length of lessons, and periods of study suitable for children of different ages; anthropometrical and physiological observation forms in use in various schools with a view to preparing a typical form for general use; anthropometrical and physiological observations recorded in different schools for a series of years on the same children; investigations into the causes of defective eyesight in school children and a definition of the conditions necessary for preserving the sight; the practical knowledge of hygiene possessed by school teachers. Much interesting information has been collected and tabulated, and it is hoped that when the final report is presented next year some action will be taken upon its recommendation.

Given pupils in a condition to study with profit, it is desirable that the teachers should be trained to direct their mental activities. In a paper on the preliminary training of teachers, with special reference to women, Miss L. E. Walter described the various avenues to qualification as teachers in elementary schools, and suggested some practicable improvements in the courses of study pursued between the ages of about fourteen and eighteen years. She condemned the excessive book-work which must be done by pupil teachers who desire to pass their examinations, especially when scientific subjects are concerned. It was urged that in every pupil teachers' school or centre the students should be taught (1) how to read books with permanent profit; (2) how to increase their knowledge practically by simple experiments as distinct from book-work.

In the course of a brilliant address, Prof. H. L. Withers pointed out that the problem of the training of teachers is essentially different in a primary and secondary school. In the former a considerable, though incomplete, system has been in existence for the best part of a century, while in the latter the provision made is still so defective that at least in the case of boys' schools it may be said that we have everything to do from the beginning. For the primary teacher large Government grants are given, while nothing is as yet allowed for the secondary. Primary schools are fairly homogeneous. Secondary schools display a great multiplicity of types, social and educational, day and boarding. The problem in the two cases was, therefore, treated separately by Prof. Withers. As regards the latter, it was remarked that the multiplicity of types is so great that anything like a single stereotype system of training would be futile. The secondary schools themselves must take a large share in framing an elastic variety of systems, and the training provided must be consistent with all that is best and strongest in our existing tradition. Analogy with other professions suggests that a combination between the great schools and the Universities is essential for the institution of a complete system of professional training. Though in several respects the position of men as regards training is quite distinct from that of women, yet for the purposes of both who desire to obtain their professional training at universities, each university should, for the future, be equipped with a department of education as effective as its departments of law and medicine. As much as possible should be done to refer students to the principles of mental, moral and physical science, upon which the theory and practice of education must ultimately be based.

In secondary schools a knowledge of educational principles is not regarded as of much importance, and young men go to them to teach without having received any training. In the course of time some of them became good schoolmasters, gaining experience at the expense of their pupils. In such cases the school has the same relation to the teacher as the workshop to the engineer, but there is little doubt that the master and the engineer should receive some practical training before undertaking professional duties. Prof. Perry's presidential address on the training of engineers was discussed at a joint meeting with the Section of Engineering. Among the points brought forward in the course of the discussion were, that it would be an advantage if students of engineering could spend five months each year in a workshop and five months in a technical college; that preliminary training in habits of observation and accuracy was of the greatest value; that teachers should be kept in close touch with the practice of their profession, and their laboratories should be equipped with modern tools and machinery; and that we have little to learn from Germany in the matter of education or of turning out work, but much to learn as regards financial ability and the science of commerce.

Language is an important factor in determining commercial developments. It is therefore worth while to consider Sir Frederick Bramwell's suggestion that the great commercial nations—the United States, Germany, France and England—should each adopt a common language to be learnt in addition to their own, in order to facilitate intercommunication and save the trouble of learning several languages for business purposes. Italian was suggested as a suitable language for the purpose, because it is easy of acquirement, founded upon a classic basis, and could be adopted without arousing feelings of jealousy among the nations accepting it. Latin was also suggested as a suitable common language, as it was in mediæval times.

Many people believe that English will in the course of time become the language of commerce, but if this is to be realised more attention must be paid to the teaching of our mother tongue in schools than is usually the case. Mr. P. J. Hartog dealt with this subject in a paper which led to a good discussion. He held that a mastery of our language is as necessary for the so-called practical uses of the leaders in war, diplomacy, science and commerce as for the historian and the philosopher. Though

on the grounds of utility English ought to be given an important place in the school curriculum, it is one of the most neglected subjects. The result is that few boys leaving school are able to write a good letter, and many adults are unable to describe things or events in precise terms. On this account many misleading statements are made which might have been avoided. Mr. Hartog pleaded for the rational and systematic teaching of the mother tongue in our schools. By neglecting this subject the teacher is deprived of a very powerful instrument of education. Prof. G. M. Minchin gave, in a paper, a number of examples of the misuse of common English words and expressions, among them being split infinitives, *without* instead of *unless*, misplaced *shall* and *will*, and many others which should be avoided by all who desire to use words in their correct sense and place, and preserve our language from barbarisms.

Other subjects were considered during the meetings of the Section, but limitations of space will not permit descriptions of them, or of the many valuable points brought forward by speakers in the discussions. It was evident from what was read and said that a large amount of material of interest to men of science and practical teachers is available, so the Section is likely to be even more active in the future than it has been during its two years of existence. R. A. G.

BOTANY AT THE BRITISH ASSOCIATION.

THE semi-popular lecture was given on Monday, September 15, by Prof. F. W. Oliver, on ancient and modern seeds. The lecturer gave a clear and interesting description, illustrated with lantern slides, of the gradual evolution of the seed, and dealt with some of the more interesting questions concerning the morphology of various seed structures.

On Friday, September 12, the botanists paid a visit to the Belfast Botanic Gardens, and under the guidance of the able curator, Mr. McKimm, inspected the extremely interesting fernery which has recently been constructed. On Tuesday afternoon, the Rev. C. H. Waddell, the indefatigable local secretary of Section K, conducted a botanical excursion to Colin Glen. After an interesting ramble, the members were entertained to tea by Mr. and Mrs. Kidd, whose kindness was much appreciated.

Much interest was taken in a collection of characteristic Australian plants, exhibited by Mr. Thomas Steel during the meeting.

Prof. I. Bayley Balfour, F.R.S., exhibited and described specimens of the various forms of *Erica tetralix* found in Connemara. Mr. James Stirling, Government Geologist of Victoria, in a paper on the flora of the Australian Alps, dealt with the origin and distribution of the mixed types of plants now growing on the highest altitudes over south-east Australia, and their correlation with other Alpine and the Tertiary floras of the region.

Mr. R. Lloyd Praeger read a paper on the composition of the flora of the north-east of Ireland. This area includes the counties of Down and Antrim, and the flora numbers 820 species of flowering plants and vascular cryptogams, the total flora of Ireland being reckoned at 1020 species. There is in the local flora an almost complete representation of British type plants. English type plants are rather poorly represented. Scottish type plants reach in Antrim their maximum for Ireland ; in Down they are somewhat fewer. Of Highland type species there is a fair representation ; Antrim, though of less elevation, contains more Alpine plants than Down. Germanic plants are extremely few in Ireland. In Atlantic type plants, Down and Antrim are comparatively rich.

Mr. Herbert Wright (Ceylon) contributed a paper on foliar periodicity in Ceylon, in which he showed that some trees undergo complete defoliation twice per year ; others exhibit incremental foliar activity several times per year, in addition to a complete annual renewal. The irregularity of foliar periodicity is very pronounced. There is not a month when all the trees are in full leaf.

In the department of plant physiology, Prof. J. C. Bose, of Calcutta, gave an interesting demonstration, illustrated by experiments, on the response of plants to stimulation (*vide Journ.* Linn. Soc., xxxv., 1902). Mrs. D. H. Scott gave an account of the movements of the flower-buds and flowers of *Sparmannia africana* up to the time of the setting of the fruit. At first the buds hang all in one plane ; each bud has a joint on the stalk, which is much swollen below the flower. The buds rise one by one from the drooping position to the horizontal ; then make a sharp curve inwards, and just before flowering the bud hangs down in an exactly vertical position. The flowers open during sunlight at a temperature not below 60° F. (15°·5 C.), so that on a cold day perhaps only one flower and on a hot day three or four may be open at the same time. The flowers reopen for several days ; during this time they gradually take up a vertical position, pollen often being formed for five or six days. Then, if fertilised by bees, the flower-stalk falls again into the horizontal position, from which it rises again as the fruit ripens. Mr. Barnard and Prof. Allan Macfadyen, in a paper on luminous bacteria, stated that these organisms require particular and exact conditions in order to exhibit their luminous properties. They must have a suitable nutrient soil containing such proportions of salts as shall render the medium isotonic. A supply of free oxygen is essential ; in the absence of oxygen the organisms live, but are non-luminous. The luminosity appears to be due to the vital processes of the cell, and an exposure to the temperature of liquid air does not destroy it. Prof. Macfadyen and Mr. Rowland also contributed a paper on the suspension of life at low temperatures, in which they showed that ten hours' exposure to the temperature of liquid hydrogen (about − 252° C.) had no appreciable effect on the vitality of the various organisms (bacteria and yeast) tested. Miss Gabrielle L. C. Matthaei (Cambridge) described experiments on the effect of temperature on carbon dioxide assimilation in the leaves of the cherry laurel. The lowest temperature at which assimilation could be detected was − 6° C. This is the first well-established case of assimilation below 0° C. For temperatures between − 6° C. and 33° C. it was found that assimilation is affected in exactly the same way as is respiration. Provided the illumination is sufficient, the assimilation increases with the temperature. Dr. Henry H. Dixon (Dublin) gave an account of some experiments made to determine the resistance of seeds to high temperatures. The maximum temperature to which the various seeds were exposed and still retained their germinating power varied from 90° C. to 121° C. The president communicated a paper by himself and Mr. H. Jackson on the germination of fatty seeds. In the case of Ricinus, the reserves consist mainly of oil and aleurone, hardly a trace of carbohydrate being present. In germination, the oil diminishes and both cane sugar and glucose make their appearance, accompanied by the formation of lecithin, a fatty body which contains nitrogen and phosphorus.

Several important papers on fossil plants were read. Miss Margaret Benson described the seed-like fructification of *Miadesmia membranacea*, Bertrand. The foliage leaf bears a ligule in a longitudinal groove with thickened base and sides. In the sporophylls, the sporangia are inserted singly in the proximal end of the groove, and are large and pedicellate. In the megasporophyll, the sides of the groove are completely coherent above the sporange, and thus form a velum. The wall of the megasporange is composed of several layers of isodiametric cells, and encloses a single thin-walled megaspore or embryo sac. The microsporange has no velum, and the wall is formed of a palisade layer. Miss Benson also described the structure of some sporangia found associated with petioles and other fragments of *Lyginodendron oldhamium*. Mr. Lomax described two specimens obtained from Dulesgate, which show that Lyginodendron had a branching stem ; also that the branch was given off in the one case between two leaf-stalks and in close proximity to several roots. The position of the roots shows that they must have been aërial roots, and not, as generally accepted, basal or confined to the basal regions of the stem. Mr. Lomax also read a paper on the occurrence of nodular concretions (coal balls) in the Lower Coal-measures. These bodies consist of a quantity of fragments of short pieces of stems, &c., some with the cortex, some without, some split in fragments, and so on. From an examination of these nodules it appears that, at least in this case, these plant remains have not grown on the spot where we now find them, and the author comes to the conclusion that the various portions of plants have been carried into their present position after being broken in fragments, and before petrification, or they have been carried from a parent bed after petrification. In a paper on sporangiophores as a clue to affinities among Pteridophyta, Dr. D. H. Scott, F.R.S., pointed out that some years ago he suggested the probability of an homology between the ventral sporangiophores of Sphenophyllum or Cheirostrobus and the similarly placed synangia of

the Psiloteæ; on this ground, among others, an affinity between the fossil and the recent family appeared tenable. This view has recently been supported by Prof. Thomas, of Auckland, N.Z., on evidence drawn from certain remarkable variations which he observed in the genus Tmesipteris. On the view suggested, the synangium of the Psiloteæ is neither a reduced strobilus nor a septate sporangium, but a ventral sporangiophore bearing a variable number of sporangia, normally two or three, according to the genus. Mr. A. C. Seward, F.R.S., and Mr. Arber gave an account of some fossil Nipa seeds from Belgium.

In the domain of plant morphology, several interesting papers were communicated. Mr. John C. Willis, director of the Royal Botanic Gardens, Peradeniya, described the dorsiventrality of the Podostemaceæ, and showed that it extends both to the vegetative and floral organs. The more modified types show a progressive increase in dorsiventrality of the vegetative system followed throughout by an increase in that of the floral. The same series, regarded ecologically, shows that though the flowers are steadily more and more zygomorphic—a condition usually regarded as an adaptation to insect visits—we have here flowers which stand stiffly erect, and are more and more anemophilous and autogamous. Miss Sibille O. Ford (Cambridge) gave an account of the morphology of the Araucarieæ, which include the two genera Araucaria and Agathis; they are characterised by the regularity of their branching and the persistence of their leaves. The apex of the stem shows no definite apical cell, but a somewhat irregular dermatogen. Well-marked annual rings may be found in the wood, and bordered pits are found on the tangential walls of the latest formed summer wood. Mr. Herbert Wright (Ceylon) described the sex relationships in Ceylon species of Diospyros. These plants have hitherto been regarded as diœcious, but he finds from an examination of fresh material frequent departures from this condition, some being monœcious, others diœcious and polygamous, and others diœcious, monœcious and polygamous. Mr. Worsdell gave an account of the various theories as to the nature of the sporangial integuments in various groups of plants. The author maintains Čelakovsky's view that in the ferns the *soriferous segment of pinnule*, bearing as a rule sporangia on its lower (dorsal) surface, is the homologue of the outer integument of the ovule in Angiosperms, and *indusium* that of inner integument. Mr. Worsdell also read a paper on the nature of the vascular system of the stem in certain dicotyledonous orders, in which he comes to the conclusion, from anatomical data, that no hard and fast line exists between the two classes of dicotyledons and monocotyledons. The flowering stem and peduncle, as being those parts of the caulome which have undergone least modification owing to the necessities of adaptation to external conditions, exhibit, as a rule, most clearly the primitive structure which in the vegetative parts has become obscured. Mr E. A. Newell Arber (Cambridge) read a paper on the morphology of the flowers in certain species of Lonicera. The genus includes about seventy species which belong to the section Xylosteum. In this section, the gynœcea of a two-flowered dichasium are more or less completely united together. In some cases, the two inferior ovaries are united in one plane by *the union of their receptacular walls*. In others they are for the most part free from one another, but surrounded by an outer parenchymatous tissue, arising from the base. This tissue is the result of the *fusion of the bracteoles* of the true flowers. Mr. Harold Wager communicated some of the results of his recent observations on the structure of the central body in various species of Cyanophyceæ which show that, although wanting some of the characteristics of the nuclei of higher organisms, it must be regarded as nuclear in character and possibly as a nucleus of a simple or rudimentary type. In another paper, Mr. Wager dealt with the function of the nucleolus. This body, in the cases examined by him, appears to be intimately connected with the nuclear network, and contains chromatin material which contributes directly to the formation of the chromosomes. Prof. Oliver and Miss Edith Chick had a paper on the morphology of *Torreya myristica*, in which some interesting features of morphological importance were described.

Among other papers brought before the Section were the following contributions from mycologists:—Miss Lorrain Smith described a disease of the gooseberry which attacks the hard stem of the bushes above and below the ground level. The inner bark is permeated and completely destroyed by the mycelium of a fungus. The outer bark cracks and splits, and sclerotia are formed on the outside or half embedded in the cortex. Mr. Barker (Cambridge) gave an account of the fungus of Samsu, a fermented drink of Eastern Asia, obtained by the distillation of a fermented liquor prepared from rice. The conversion of the starch into fermentable sugars is due largely to a species of Monascus. Hitherto this genus has been placed in the Hemiasci on account of a supposed formation of spores in a sporangium, surrounded by an investment of hyphæ. It is, however, one of the simplest sexual Ascomycetes. Mr. E. M. Freeman (Cambridge) contributed a paper on the darnel seed fungus, in which several new and important facts were brought forward.

H. W.

CARLSBAD MEETING OF THE GERMAN ASSOCIATION OF NATURALISTS AND PHYSICIANS.

THE seventy-fourth annual meeting of the Association of German Naturalists and Physicians was held on September 21–28 at Carlsbad, after an interval of not less than forty years. At the meeting, very naturally, the hot springs for which the place is famous suggested a suitable subject for discussion. Geologists and chemists alike concentrated their attention upon them. Prof. van 't Hoff, who may be regarded as the veritable creator of modern theoretical and physical chemistry, was there to elucidate the subject. Prof. Meyerhofer applied the latest teaching of that particular science to the springs, exciting a keen interest by his masterly method of dealing with the subject, more particularly when entering into the newest discoveries with regard to the theory of osmotic pressure and of ions which van 't Hoff and Arrhenius have effectively established. The entire organism in biology may be shown to be a collection of osmotic cells, enclosing saline solutions, and the movement of liquids in them is to a high degree, if not entirely, determined by the laws of osmotic pressure.

The Carlsbad springs have been again and again subjected to osmotic analysis, and this has led to a considerably deeper insight into the cause of their hygienic action than the merely chemical analysis which had first been judged sufficient. Mineral waters of high osmotic pressure, so it has been ascertained, remain in the stomach longer than waters of low osmotic pressure, and this fact enables the physician the better to judge what kind of water should be selected in dealing with any particular affection of the stomach. The study of the waters has been carried further, and the value of certain distinct rules and modified methods has been ascertained as facilitating comparison in respect of osmotic pressure between mineral springs and liquids occurring in the human body. Among other results, it has been shown that natural mineral waters are much more efficacious than artificial imitations. Very possibly this is due to the presence in the natural springs of certain chemical substances held in solution in such infinitesimal quantities that make them escape the notice of the purely chemical analyst. Such undiscovered ingredients may very well act by catalytic methods and so increase the efficacy of the solution.

That question, indeed, requires further elucidation, which is likely to prove of much benefit to balneological science, to the relief of suffering humanity.

Another lecture of great interest was that delivered by Prof. Suess, of Vienna, on the nature of hot springs. The mineral springs which are due to infiltration from surface water go by the name of "vadose" springs; they may be either cold or hot, according to their depth. It has been proved in the case of more hot springs than one that they run along earth crevasses formed before their own origin. Thus at Carlsbad the springs have followed the preexisting metallic veins (ore-lodes) which thousands of years ago found an outlet from the interior to the surface. The Carlsbad springs yield yearly about 5·6 million kilogrammes of solid ingredients which originate in the interior of the earth and contain in correspondingly small quantities the same elements as the ore-lodes the course of which they follow. Carlsbad is therefore manifestly a "juvenile," *i.e.* volcanic, water. Attempts made to search for an area of infiltration (as for "vadose" waters) or to estimate the depth of its origin from any kind of a so-called thermal scale have proved absolutely futile. Nor yet can the presence of mineral ingredients be explained by the nature of the granite through which they run to the surface. The cavities which were long supposed to have been formed by the continual effusion of 5·88 million

kilogrammes of fixed ingredients annually are due to an entirely different cause. Carlsbad, it ought to be remembered, stands on a spathic lode of horn stone. Whether its hot waters in the depth still precipitate heavy metals and are active in building up a metallic vein, reaching finally daylight in an impoverished state, or whether the conditions of to-day do not admit of such an activity, it is impossible to say. The presence of arsenic, antimony and zinc, indeed, favours the former conclusion.

The Congress held general meetings in which very interesting communications were made. Thus, Prof. Weber, Amsterdam, had much to say upon the Malay Archipelago and the history of its fauna. He reconstructed, so to speak, the great bridge between the people of East Asia and Australia. Again, Prof. Voller, director of the Electrotechnical Institute of Hamburg, explained the foundation and methods of electrical wave telegraphy. Communications showed that very substantial progress has recently been made, thanks to the theoretical study of the subject by Prof. Braun, of Strassburg, and the practical experiments of Prof. Slaby, of Charlottenburg. Some practical demonstrations of what has been called the Slaby-Braun system, for which the Congress was indebted to the General Electrical Company, of Berlin, and the Society for Wireless Telegraphy (by the Braun and Siemens-Halske process), of Berlin, helped to make the matter very much clearer.

The Carlsbad Congress, which was, according to established usage, held in a number of distinct sections—28 in all—was opened with a very interesting address on the constitution of the molecule of albumen, by Prof. Hofmeister, of Strassburg. Investigation of this important subject is beset by difficulties. However, in spite of this, modern science has, by means of continued inquiry, succeeded in establishing certain valuable facts which promise to lead to a clear knowledge of the subject. Thus it has been ascertained that glycocol, which is derived from albuminoid bodies, becomes transformed into urea. Therefore the road to further discovery must, one would think, lie across glycocol, and we can unconstrainedly trace back the other principal nitrogenous final products, just like urea, to the splitting up of the molecule of albumen, and *vice versâ* we might reconstruct the molecule of albumen from the final products.

Prof. Emil Fischer, of Berlin, in the Section of Chemistry, spoke on practically the same subject in an intensely interesting way. He was able to state that he succeeded in obtaining albuminoid substances by synthesis the possibility of which had so far only been dreamed of.

Furthermore, Prof. Leube, of Würzburg, reviewed the whole question of physiological albuminuria (both "manifest" and "latent"). He showed that in some healthy individuals albumen passes in the urine regularly after standing, whereas it disappears when the persons affected alter their position to sitting or lying. Muscular exertion may also be productive of albuminuria, but only in a standing position. Food of itself causes no albuminuria. It may, indeed, result, after the eating of raw eggs, but only when the person eating them has been standing. Such disposition to albuminuria is probably owing to an innate greater transfusibility of the filtrating membrane of the kidney. It is innocuous. Prof. v. Eiselsberg, of Vienna, dealt with the subject of the thyroid gland. His paper showed that goitre is caused by some mineral constituents occurring in certain geological formations and transmitted by water. In all probability, cretinism is due to similar causes, made effective through the action of the thyroid gland. Prof. v. Wettstein, of Vienna, made "Neo-Lamarckism" his subject, and explained the great importance of "selection" in the development of species, showing that by "selection" alone is it possible to account for the remarkable variety of forms to be observed in the same scale of organisation. The argument is, however, manifestly incomplete. For "selection" cannot account for the progress of development which, on the other hand, "direct accommodation" does explain.

Prof. Penck, of Vienna, in his paper on prehistoric man, proved that the interval between the older and the younger Stone age can only have been a very short one. In future, therefore, we will have to consider rather an advance of the culture of the younger Stone age than an immigration of Neolithic people, bearing in mind that, according to the present standard of our knowledge, Europe is the scene of a prehistoric culture the beginning of which lies a few hundred thousands of years back.

So much for the general meetings. The sectional gatherings proved no less interesting and instructive. In the Pedriatric Section, Dr. Moser, of Vienna, threw new light upon the theory, still to be proved, of the unity of species of the streptococci in scarlet fever. He has used a mixture of bouillon-cultures of streptococci from various cases of scarlet fever for immunising animals. In this way he has obtained a serum from horses which was shown to possess a specific curative value in scarlet fever when tried in the pedriatric clinic of the University (Prof. Escherich). The serum, which was prepared in the Serotherapeutical State Institute (Prof. R. Paltauf), has been used in the clinic since November, 1900. Of 699 scarlet fever cases of St. Anna Hospital, the worst were picked out and 81 received injections. It is the clinical aspect which in all these cases speaks for the specifically curative effect of the serum. If the injection is made on the first or second day there is no death; at a later period the result is less certain. The effect of the injection is that the fever vanishes or subsides, the general feeling improves in a remarkably short time, the nervous disturbances disappear very rapidly, the children feeling surprisingly better. Up to now it has proved necessary to inject the serum in considerable quantities, and the effect has sometimes been that sensitive children have suffered in consequence from eczema. This, however, passes away speedily without causing any injury. In the St. Anna Hospital it was found possible to lessen mortality to 8·9 per cent. out of almost 400 cases, whereas in the other hospitals of the town the average mortality was 13·09 per cent. Yet these results were obtained under partial application of the method, owing to the insufficient quantities and low concentrations only of the serum being available, so that only a fraction of the sick could be subjected to this treatment. Prof. Escherich spoke energetically of the favourable action obtained with the serum. Prof. Paltauf expressed regret that the quantity of serum necessary cannot yet be precisely determined, as is the case with the diphtheria serum. The Government has, however, granted the Serotherapeutical Institute an exceptional subsidy of 10,000 kr. so as to produce this scarlet fever serum in sufficient quantities.

In the Section of Dentistry, Dr. Sickingen furnished really astounding material illustrating the necessity of paying careful attention to the teeth of soldiers. As a result, an appeal was made to the Ministry of War recommending that garrison dentists should be appointed in the army. Furthermore, the Section of Hygiene adopted a resolution urging that as a means of raising the general hygienic condition of the people, special district dentists and school dentists should be appointed by the State and prohibited from engaging in private practice. Dr. Sternberg, in the Section for Pathological Anatomy, related that dead tubercle bacilli may bring about the same anatomical changes as living ones, causing the death of the animals experimented upon. Dr. Kraus, Vienna, spoke of the action of immune-hæmolysine (the serum of rabbits treated previously with canine erythrocytes); small quantities of such serum have been found to produce a grave disease which has been characterised as hæglobinæmia, hæmoglobinuria, grave anæmia or possibly icterus. Prof. Takahasi (Tokio) spoke on poisonous fish. Of such he showed the Tetrotone (called "Tugu" in Japan) to be the most poisonous of all. Its ovary contains most of the poison, the next dangerous being the liver; the muscles, on the other hand, are entirely free from the poison. Accordingly, a police regulation has been enforced, permitting the sale of this fish only after the internal organs have been removed.

Prof. Frick, Zurich, spoke of the treatment of feverish diseases without alcohol, and aroused considerable interest in view of the bearing of this matter upon the anti-alcoholic movement. He said that the popularity of alcohol is entirely due to its quality as a narcotic. Alcohol, however, possesses a number of qualities which make its use seriously contra-indicated in the ward altogether, and more particularly in febrile diseases. Moreover, the power of resistance against infectious matter is abated in the animal organism by the consumption of alcohol, and this is the reason why drinkers show in any kind of infectious disease a lesser power of resistance than people who practise abstinence.

Another question of great interest raised in the proceedings was that of the "circuit of nitrogen." Among the highly instructive communications which were made on the subject, space will permit me here to mention only one. Prof. Meyer, of Göttingen, began his paper with these words:—"Cellulose must become a food stuff." He pointed out the necessity for nitrogen both in vegetable and animal life, and the importance

of preserving it and turning it to practical account in the economy of nature. The population of the German Empire, so he instanced, increases at the rate of one per cent. every year, yet the quantity of nitrogen provided for our sustenance by the ordinary channels remains constantly the same. We shall, therefore, have to take advantage of the free nitrogen present in the air, first to benefit the plants and indirectly to benefit the plant-eating animals. It is known that small organisms, such as the so-called nitrifying bacteria, are able to assimilate directly the free nitrogen occurring in the atmosphere. The immense importance of this economic question is understood upon realising that in the German Empire an area of twelve-and-a-half million acres is covered with lupins and other leguminous plants, cultivated for agricultural purposes, and that these maintain a close touch ("symbiose") with the nitrifying bacteria. The nitrogen of the air which these bacteria attract on such an area may amount to five million quintals, representing at the current market rate something like 300,000,000 marks.

In the Section of Legal Medicine, the director of the Forensic Institute of Graz spoke of the serum diagnostic of blood, and pointed out the difficulties and responsibility involved. Jolles insisted upon the importance of chemical examination of blood, and explained some clinical apparatus which he has devised for such purpose, viz. the ferrometer, the phosphometer and the hæmoprometer.

In the Botanical Section, Prof. Molisch, of Prague, in his paper on the phosphorescence of meat, described the method by which it is possible to obtain such with the certainty of a physical experiment. It is invariably the same micro-organism which causes the phenomenon, namely, the *Micrococcus phosphoreus*, Cohn, a bacterium which has made itself at home all over the continent, though it may be true that it came originally from the sea. Prof. Pribram, Vienna, spoke of the new institute for biological investigation in Vienna, in which it has been made possible to observe an organism during several generations and of studying the principal question of biology, namely, the transmission ofacquired characters. Prof. Roehman, Breslau, showed that he had succeeded in keeping mice in the best of health with food consisting of albuminates, carbohydrates and salts mingled in a certain ratio. Prof. Exner, Vienna, with the help of an "acousto-meter," demonstrated that the bad acoustic properties of many public rooms are due in the main to the existence of an echo. Police-Surgeon Dr. Schrank, in the Section for Hygiene, advocated international legal proceedings to prevent the spreading of venereal diseases.

An important demonstration took place in the Section of Mathematics after Prof. Klein, Göttingen, had finished his report on the present condition of the "Encyclopædia of Mathematical Sciences." Prof. Molk, Nancy, added that this great work is now being edited in common by German and French authors, and that this is the first occasion since 1870 that men of science of either side of the Vosges have been brought into active cooperation. In the Section of Astronomy, Prof. Archenholz, of the Treptow Observatory, mentioned that in the determination of the influence which sun spots have on our atmosphere, it is rather the position of these spots and their size on the solar disc than their number which enters into account. Prof. Hasslinger, of Prague, in the Chemical Section, relates the results of his latest experiments by which he has secured diamonds with Goldschmid's thermite method. By adding carbon in various forms, such as that of finely suspended graphite to a fused mass, similar to the South African mother stone Kimberlit, he succeeded in obtaining true diamonds. This is not only an entirely new method, but also corroborates the theory previously maintained of the natural origin of diamonds.

In the Section of Gynæcology, the conservative treatment by bath cures, mud poultices, hot baths, thermophor, &c., was forcibly advocated as yielding complete success and as well qualified to substitute the radical operations, while pus-formation can be stopped by incision only. Prof. Chroback, of Vienna, pointed out that even so pronounced a radical as Prof. Martine expressed himself in favour of the conservative method. Prof. Kehr, of Halberstadt, gave a *résumé* of no less than 730 operations executed for the removal of gall stones. Where gall stones were removed from the gall bladder, mortality was found to be at the rate of 2 per cent., when the gall bladder was removed with the stones it rose to 3 per cent., and when the stones occurred in the hepatic duct to 6·5 per cent.; however, by continual practice he managed in the last 200 operations to restrict mortality to only $1\frac{1}{2}$ per cent.

From these short notes it will be seen that there was abundant material of a very varied character brought under the notice of the Congress, and dealt with in a manner to make the latter a not unworthy successor of its precursors. Science generally has distinctly gained by its transactions. The next Congress is to be held September 21, 1903. F. SCHUMAN-LECLERCQ.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The 240th meeting of the University Junior Scientific Club was held on October 31. Dr. A. D. Darbishire, Balliol, showed an interesting case of reversion. The offspring of an albino pet mouse and a Japanese "waltzing" mouse bears many resemblances to a common house mouse, and does not "waltz."

Mr. H. M. Hartley, Balliol, read a paper on "Jöns Jakob Berzelius."

Mr. W. K. Spencer (Magdalen) has been elected to the Burdett Coutts' scholarship in geology.

The Chemistry School suffered a heavy loss at the beginning of the present term in Mr. Vernon Harcourt's resignation of the Lee's readership, which he held for forty-three years. Mr. Harcourt was a Balliol undergraduate, and in 1858 was placed in the first class in the Natural Science School. During the next year he was elected to the Lee's readership at Christchurch. In addition to his research work, he took an important part in the teaching of chemistry. He did not merely train his pupils in the ordinary curriculum required for the schools, but imbued them with the ambitions of the researcher, and it is a striking testimony to his efforts that the best experimental work by Oxford men of the present generation has come from those who were his own pupils or worked under his influence. His departure from Oxford will be greatly regretted by very many friends both young and old, and he will leave behind him a place which it will be very hard adequately to fill.

CAMBRIDGE.—In the combination room of Peterhouse on Wednesday of last week, Lord Kelvin unveiled a portrait of the late Prof. P. G. Tait, honorary fellow of the college, who was senior wrangler and first Smith's prizeman in 1852. The portrait, which was subscribed for by the master and fellows of Peterhouse, was painted by Sir George Reid, president of the Royal Scottish Academy, and it will be hung in the hall of the college by the side of the portraits of Lord Kelvin and the late Dr. H. W. Cookson. The *Times* reports Lord Kelvin to have said, in the course of his remarks, that he valued most highly the privilege of being allowed to ask the master and fellows of Peterhouse to accept for their college a portrait of Prof. Tait. He felt specially grateful for this privilege as a forty-years' comrade, friend and working ally of Tait. The master of Pembroke (Sir George Stokes) spoke of Prof. Tait as an intimate friend, and said all who knew him must have been impressed with his great ingenuity and the versatility of his genius.

Mr. F. C. Kempson, Caius, has been appointed a demonstrator of anatomy.

The following are the examiners for the natural sciences tripos:—Physics: Prof. L. R. Wilberforce, F.R.S., and T. C. Fitzpatrick; chemistry: C. T. Heycock, F.R.S., and H. McLeod, F.R.S.; mineralogy: A. Hutchinson and G. F. Herbert Smith; geology: H. Woods and Prof. T. T. Groom; botany: Prof. Ward, F.R.S., and D. H. Scott, F.R.S.; zoology: J. S. Gardiner and Prof. Graham Kerr; physiology: W. B. Hardy, F.R.S., and E. H. Starling, F.R.S.; anatomy: N. B. Harman and Dr. A. Keith.

Dr. W. H. R. Rivers, University lecturer in experimental psychology, has been elected a fellow of St. John's College.

Mr. H. O. Jones, Jacksonian demonstrator of chemistry, has been elected a fellow of Clare College.

DR. R. H. ADERS PLIMMER has been appointed Grocers' Company research student at the Jenner Institute of Preventive Medicine.

SIR GEORGE KEKEWICH, who has been secretary to the Board of Education since 1890, has resigned his appointment and has been succeeded by Mr. R. L. Morant.

DR. H. S. CARSLAW has been appointed professor of pure and applied mathematics in the University of Sydney. He was fourth wrangler (bracketed) in 1894, and is lecturer in mathematics in the University of Glasgow, and Fellow of Emmanuel College, Cambridge.

THE Vienna correspondent of the *Times* states that according to a communication from St. Petersburg, the Russian Ministry of Agriculture has just decided to found an agricultural high school for women. Students at the school will receive a general training as agriculturists, or will be permitted to restrict their attention to special branches of agriculture, such as dairy farming, gardening, bee culture, poultry keeping and cattle and sheep breeding. The course has been fixed for three years and will include practical occupation on a model farm in addition to study and laboratory work. Although the date on which the new institution will be opened has not yet been decided upon, 325 women who have had an intermediate education have announced their intention to follow the course.

A RESEARCH scholarship of the annual value of 200*l*. for the study of the thymus and other ductless glands has recently been founded by Mr. J. Francis Mason, of Freeland Lodge, Woodstock, Oxfordshire. The scholarship is tenable for two years, but the period may be extended to three years. The medical papers announce that on the recommendation of Prof. G. Sims Woodhead, of Cambridge, and Dr. T. F. S. Caverhill, of Edinburgh, Dr. Swale Vincent, lecturer on histology at the University College, Cardiff, has been appointed the first scholar. In addition to the foundation of the scholarship, Mr. Mason has made a donation of 200*l*. to the laboratory of the Edinburgh Royal College of Physicians to enable the medical superintendent, Dr. Noël Paton, to carry out a combined research on ductless glands.

THE chief of the circulating department of the New York Public Library has recently undertaken an inquiry into the kind and amount of the reading of scientific subjects which takes place in connection with the eleven branches of the New York Library. During May, 1901, the total home circulation of books from the eleven branch libraries was 131,700, and that of books of science 8553, or 6·5 per cent. The most popular subjects of science during the month concerned were, in order, zoology, mathematics, physics and botany, the least popular of the ten sciences tabulated being palæontology, on which subject there were only twenty-four books in all the libraries put together, and of these only four were borrowed during the month. But a month is too short a time for the investigation, and little importance can be attached to the results.

THE report of the Somerset County Education Committee for the year ending March 31 last shows that very few changes were made during this period in the system of technical education existing in the county of Somerset. The committee continues to encourage agricultural research. For instance, a grant of 100*l*. a year for three years has been made to the Bath and West and Southern Counties' Society in aid of a research by Mr. F. T. Lloyd into the causes of production of flavour in dairy produce, the Board of Agriculture contributing 200*l*. per annum and the Bath and West Society 150*l*. per annum for the same purpose during the same period. A grant of 25*l*. has also been made in aid of the expenses of experiments on the influence of the manuring of pastures on the growth of sheep fed thereon, to be carried out on Lord Ebrington's estate on Exmoor.

WE have received from Sir Philip Magnus the report, for the session 1901–2, on the work of the department of technology of the City and Guilds of London Institute. Among other matters described are the steps by which arrangements have been made for coordinating the technological work of the Institute with that of the Board of Education for England and Wales and of the Scotch Education Department. These arrangements are to be welcomed as helping to systematise technical instruction and as tending to prevent the overlapping of effort which, in educational matters, has generally led to waste and inefficiency. They mark another step towards the unification of different educational activities under a central board. The work of the department of technology of the Institute continues to grow steadily. During the session, the number of classes registered by the Institute increased from 2222 to 2320, and the number of students in attendance at these classes from 34,246 to 36,189. The total number of candidates for examination in Great Britain and Ireland was 16,580, showing an increase of 1023 on the number presented in 1901.

SOCIETIES AND ACADEMIES.

LONDON.

Entomological Society, October 15.—Prof. E. B. Poulton, F.R.S., vice-president, in the chair.—Mr. A. J. Chitty showed an entirely black specimen of *Metoecus paradoxus* as tending to disprove the mimicry suggested by him at the meeting on October 1. Dr. Chapman said that in his experience one out of every six specimens of this species was black. Mr. Donisthorpe stated that out of about one hundred specimens he had never caught or bred a black Metœcus.—Mr. E. P. Pickett exhibited a variety of the female of *Argynnis aglaia*, varieties of *Satyrus janira*, and a long series of *Lycaena corydon* taken near Folkestone and Dover in August last, including four males of the last-named species, with the black band on the edge of the forewings much deeper than usual; also twelve dwarf male specimens of this species, four dwarf females and many other aberrant forms. Mr. Goss said this dwarf form of *L. corydon* occurred constantly in one valley about two miles east from Dover, but he was unaware of its occurrence elsewhere in this country. He remarked that a dwarf form of *L. arion* occurred everywhere where the type was found, both in Gloucestershire and Cornwall. Dr. Chapman and Mr. Sloper also remarked on the dwarf form of *L. corydon*.—Dr. Chapman exhibited specimens of *Notodonta* (*Hybocampa*) *dryinopa* from Queensland. It was remarkably similar in appearance, structure and habits to *Hybocampa milhauseri*. He stated that the pupa with a similar spine to that of *H. milhauseri* does not cut out a regular oval lid from the cocoon like that species, but by a stabbing process pierces it with a number of holes, so that a piece is more easily pushed off. The cocoon being covered with bits of bark, stone, &c., a cutting process would be impossible, whereas the cocoon of *H. milhauseri* was of pure gum-like silk. He pointed out that the larva much resembled that of *H. milhauseri*, but the hinder segments were more like those of *Stauropus fagi*. He also exhibited living eggs, larvæ and imagines of *Orina tristis*, var. *smaragdina*, from Pino, Lago Maggiore. The beetles were taken on May 30, and had laid many eggs. Dr. Chapman said that the embryo, ready to hatch, might be seen within some of the eggs and its hatching spines observed.—Mr. Sloper exhibited a specimen of *Lycaena hylas*, caught at Dover on September 7.—Mr. Martin Jacoby communicated a paper entitled "A Further Contribution to our Knowledge of African Phytophagous Coleoptera."—Mr. Malcolm Burr read a communication from Hofrath Dr. Carl Brunner von Wattenwyl entitled "Observations sur le nom générique Acrida."

MANCHESTER.

Literary and Philosophical Society, October 21.—Mr. Charles Bailey, president, in the chair.—Mr. C. E. Stromeyer exhibited specimens of boiler scale which both internally and externally resembled volcanoes, and he thought might with advantage be studied with the object of gaining a knowledge of volcanic eruptions.—The president read a paper on the adventitious vegetation of the sandhills of St. Anne's-on-the-Sea, in which he remarked on four aliens found in that locality, viz. *Œnothera biennis*, Linn., *Sisymbrium pannonicum*, Jacq., *Ambrosia artemisiaefolia*, Linn., and *Vicia villosa*, Roth. Although the latter plant is distributed throughout Europe, this is probably the first record of its occurrence in Britain. *Ambrosia artemisiaefolia* is also a noteworthy addition, as it is a rare casual in the few places in England where it has previously been found.

PARIS.

Academy of Sciences, October 22.—M. Bouquet de la Grye in the chair.—Demonstration of the absolute irreducibility of the equation $y'' = 6y^2 + x$, by M. Paul Painlevé.—Synthesis of the alkaline hyposulphites and of the hyposulphites of the alkaline earths in an anhydrous condition, by M. Moissan. The hydrides of the alkalis and the alkaline earths when acted upon with sulphur dioxide under reduced pressure give pure hyposulphites, the hydrosulphites of Schutzenberger. From the fact that hydrogen is given off in this reaction, it is shown that the formula given by Bernthsen, $Na_2S_2O_4$, is correct, and that the original formula of Schutzenberger, in which these substances are represented as containing hydrogen, is not in accordance with fact.—The culture of wheat at the experimental field at Grignon in 1902, by MM. Dehérain and C. Dupont. Chiefly owing to the rains in the month of May, the yield of wheat in this experimental station has been exceptionally good. The

conclusion is drawn from this that where irrigation is possible in the spring without too great an expense, the results will be very advantageous to the farmer.—Some cases of integration of the equation to the brachistochrone, by M. Haton de la Goupillière.—On cavitation in screw steamers, by M. J. A. Bormand. The name cavitation is given to the phenomenon met with when a screw is driven in water at speeds above a certain limiting value. A cavity is formed in the water inside which the screw revolves, and a further increase in the power driving the screw then results in no increase in the velocity of the boat. The alterations necessitated in the usual formulæ for screw propulsion by this phenomenon are discussed in detail.—On the velocity of propagation of the X-rays, by M. T. Blondlot. By means of the action of the X-rays upon the discharge of a Hertzian exciter, it is shown that the duration of these rays is less than 5×10^{-10} sec., and that the velocity of the X-rays is of the same order as that of the Hertzian waves.—Remarks by M. le General Bassot on the volume of the *Connaissance des Temps* for 1905.—New observations on the volcanic eruptions at Martinique, by M. A. Lacroix.—Observations on the sun made at the Observatory of Lyons with the Brunner equatorial during the second quarter of 1902, by M. J. Guillaume. The results are summarised in three tables giving the number of spots, their distribution in latitude and the distribution of the faculæ in latitude.—On the theory of algebraic functions, by M. Ludwig Schlesinger.—On Bessel's equation with a second member, by M. A. S. Chessin.—On an example of correlative transformation in mechanics, by M Paul J. Suchar.—The precautions to be taken in the employment of silk fibres as torsion wires, by M. V. Crémieu —Vision at a distance by electricity, by M. J. H. Coblyn.—The variation of the magnetic resistance of a bar submitted to traction, by M. Fraichet.—The electromotive force of a thermoelectric element, by M. Ponsot.—A method for the volumetric estimation of tannin and the analysis of wood and of tannin extracts, by M. Albert Thompson. The method is based upon the determination of the amount of oxygen absorbed from an alkaline solution of hydrogen peroxide by the tannin.—On a new base derived from galactose, by M. E. Roux. By the reduction of the oxime obtained from galactose, a new base named galactamine is obtained, the preparation and chief properties of which are described.—On a new compound of the hexamethylene-tetramine group, by M. Marcel Descudé.—On a solid acid from the oil of *Elaeococca vernicia*, by M. L. Maquenne.—On musculamine, a base derived from muscles, by MM. A. Etard and A. Vila. The base described is the first example of a triamine base among biological products.—On the origin of the natural coloration of silk in the Lepidoptera, by MM. D. Levrat and A. Conte. These researches show the possibility of passing a substance such as a colouring matter through the digestive tube on to the silk, through the blood—On the new genus Gyrinocheilus of the family Cyprinidæ, by M. Léon Vaillant.—Contribution to the study of the Anopheles of the Isthmus of Suez, by M. Cambouliu.—The physical conditions of tuberisation in plants, by M. Noel Bernard.—Observations on the germination of the spores of *Saccharomyces Ludwigii*, by M. A. Guillermond.—On the pollen of plants belonging to the genus Asclepias, by M. Paul Dop.—New experiments in maritime aeronautics, by M. H. Hervé.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 6.

LINNEAN SOCIETY, at 8.—Notes on a Natural History Journey to Chile: H. J. Elwes, F.R.S.

RÖNTGEN SOCIETY, at 8.30.—Address by the President, Mr. Herbert Jackson.

CHEMICAL SOCIETY, at 8.—Di-Indigotine: J. Moir —Note on the Localisation of Phosphates in the Sugar Cane: C. H. G. Sprankling.—The Specific Heats of Gases: H. Crompton.—On the Non-existence of the Gaseous Sulphide of Carbon described by Deninger: E. J. Russell and N. Smith.—The Action of Nitric Acid on Bromophenolic Compounds: W. Robertson.—Hydroxyoxamides. Part II.: R. H. Pickard, C. Allen, W. A. Bowdler and W. Carter.—3:5-Dichlor-*o*-xylene and 3:5-Dichlor-*p*-phthalic Acid: A. W. Crossley and H. R. Le Sueur—Isometric Anhydrous Sulphates of the Form $M''SO_4,R'_2SO_4$: F. R. Mallet.—The Catalytic Racemisation of Amygdaline: J. W. Walker.—The Combination of Carbon Monoxide with Chlorine under the Influence of Light: G. Dyson and A. Harden—The Constituents of Commercial Chrysarobin: H. A. D. Jowett and C. E. Potter.

SATURDAY, NOVEMBER 8.

ESSEX FIELD CLUB (Essex Museum of Natural History, Stratford), at 6.30 p.m.—Results of the Fungus Foray on October 17 and 18: Dr. M. C. Cooke.—Report of Delegate at British Association Meeting, Belfast: W Whitaker, F.R.S.—Lecture, "Insect Life": F. Enock.

TUESDAY, NOVEMBER 11.

SUPPLEMENT.

SUPPLEMENT TO "NATURE."

THE HISTORY OF EGYPT.

A History of Egypt from the End of the Neolithic Period to the Death of Cleopatra VII., B.C. 30. 8 vols., illustrated. Books on Egypt and Chaldæa, vols. ix–xvi. By E. A. Wallis Budge, M.A., Litt.D., D.Lit., Keeper of the Egyptian and Assyrian Antiquities in the British Museum. (London: Kegan Paul and Co., Ltd., 1902.) Price 3*s*. 6*d*. per vol.

IT is now twenty years since Egypt last changed masters, and the completion of these twenty years of British rule has been marked by the completion of a work of public utility, the great dam at Aswân, which will surpass any similar work carried out in the days of the Pharaohs. Simultaneously is published the fullest and most complete English history of Egypt under her ancient native monarchs, from the earliest times to the end of the native kingdom, a period of more than four thousand years. The publication consists of eight small and very handy volumes, all profusely illustrated with photographs and line-drawings of temples, tombs, mummies and other antiquities of the various periods, which are treated in succession. Dr. Budge may be congratulated on the production at a most opportune moment of this work, which should find a place on the shelves of everyone who is interested in the past history of the famous land which we have taken under our protection.

The history is described on the title-page as beginning with the end of the Neolithic period. But in reality Dr. Budge begins earlier than that, for Egypt was inhabited in Palæolithic days, and the fact is chronicled by her historian, who also engraves several flint implements, now in the British Museum, which are undoubtedly of the Older Stone Age (p. 85). All anthropological inquirers will be grateful to Dr. Budge for the large number of illustrations which he gives in his first volume of the weapons, implements, vases, &c., which were used by the earliest Egyptians. The Neolithic Egyptian weapons are beyond doubt the finest ever discovered, the masterpieces of the Neolithic knapper, and those who are familiar only with European or East-Asiatic types will open their eyes when they first become acquainted with those of Egypt. The vases can hardly be believed to have been made without the wheel. Yet they undoubtedly were; neither the wheel nor the lathe were known to the early Egyptians. The Neolithic vase-types, the oldest of which is the well-known red and black ware, gradually progress until they merge insensibly into those of the earliest dynastic period, which was "Chalcolithic" in character, *i.e.* copper had then come into general use.

Dr. Budge describes very fully the probable manner of life of the earliest Egyptians, his authorities being their own relics and the many valuable hints which are given us by the Sicilian historian Diodorus. He also makes clear the whole history of the discovery of these primitive inhabitants of the Nile Valley, showing how their remains were known in many museums years ago, but could not be classified, being often set down as forgeries simply because they were extraordinary; how Prof. Petrie and M. de Morgan made a series of independent but contemporary explorations, which resulted in the discovery of whole cemeteries of the "New Race" (the people to whom these extraordinary objects belonged) and of numbers of these objects, chiefly flints and vases, themselves; how the problem of the chronological position of these remarkable remains arose, and how M. de Morgan dated them rightly and Prof. Petrie wrongly; finally, how the English savant was convinced that the arguments of his French confrère were correct, with the result that all archæologists are now agreed that these remains are veritably those of the Egyptians of the later Neolithic and early Chalcolithic periods. All this, and more, is set forth in most interesting fashion by the Keeper of the National Collection of Egyptian Antiquities.

From the Predynastic period, to which the Neolithic antiquities belong, Dr. Budge proceeds to the discussion of the remains of the Early Dynastic or "Archaic" period, which was "Chalcolithic" in character, as has been already observed above. Here again the historian performs the necessary function of impartially dealing out to each explorer and archæologist the exact meed of due renown to which he is entitled for his particular services to the cause of science in the matter of the discovery and elucidation of the tombs of the earliest dynasties. Prof. Petrie's scheme for the arrangement of the earliest kings is more or less accepted, with the exception of "Dynasty O," of which the author makes no mention, probably because the phrase is a contradiction in terms, since "Dynasty O" is no dynasty. That there were local kings in both Upper and Lower Egypt before Menes is of course probable; indeed, Dr. Budge is, so far as we are aware, the first to point out that a very ancient monument, the Palermo Stele (Fifth Dynasty, about 3500 B.C.), contains the names of a whole series of hitherto unsuspected predynastic monarchs of Lower Egypt, which names, Seka, Tau, Thesh, Mekha, &c., are of a most primitive character (vol. i. p. 169). Since, however, these kings, as well as others (of Upper Egypt) identified at Abydos are mere local monarchs of the ages before Mena, they can hardly be said to belong to any "dynasty" at all, for the dynasties of All Egypt begin with Mena; and the use of the term "dynasty" for these predynastic chiefs is evidently deprecated by Dr. Budge.

In the chapter with which the second volume commences, Dr. Budge describes the advance which the "Archaic" Egyptians had made upon their ancestors of the predynastic time. The civilisation of the Archaic people he does not regard as indigenous, but as an importation from farther east, probably from Southern Arabia. He certainly seems to show that there are undoubted traces of strong Sumerian (Early Babylonian) influence in the archaic civilisation of Egypt which are absent from the older Neolithic barbarism. Further, writing begins with the dynasties. Taking these facts in conjunction with the indications supplied by several Egyptian legends (of great interest to the student of early traditions), he comes to the conclusion that the indigenous stone-using people, who were akin to the Libyans, were overrun at some period previous to the unification of the country under one king by a conquering, more highly civilised people from the east, who used copper weapons. This people invaded the Nile Valley

from the Red Sea coast by way of the Wady Hammamat. This version of a theory which has long been broached and discussed seems more probable than any other, because it does not go too far or ask us to believe too much.

From the Archaic Period, which came to an end with the Third Dynasty, about 3800 B.C., the historian passes on to the period of the great Pyramid-builders of the Fourth Dynasty, the days of the mighty Cheops, Chephren and Mykerinos, so well known to us from the pages of the Father of History. And it is wonderful how well informed Herodotus was about these ancient kings, who seem to have impressed themselves on the memories of their subjects for all time. With the Fourth Dynasty, Egyptian civilisation ceased to develop with the remarkable vigour and quickness which it had shown during the Archaic Period, and became more or less stereotyped. For many centuries, therefore, the task of the historian is the simple one of recording the reign of king after king, war after war, until with the accession of the Eighteenth Dynasty Egypt became a world-power, and subdued mankind from the marshes of the Bahr al-Ghazal to the mountains of Armenia, from the plains of Babylonia to the passes of the Taurus, to her sway. The strange reign of the religious and artistic enthusiast Khu-en-Aten is described, and the story of his shameful abandonment of the Asiatic empire of Egypt and its partial reconquest by Seti I. and his pretentious son Rameses II. (who has, it appears, no particular claim to the title "Great," which is usually bestowed upon him) is retold by Dr. Budge, and the interest of the tale is much enhanced by the contemporary illustrations of these ancient wars and sieges which he reproduces for us. We are speaking now of the fourteenth century B.C., three thousand years after the Archaic Period which we have just been discussing—*i.e.* as much time lies between the days of those monarchs of old, Mena and the rest, and the wars of Rameses and Seti as lies between these and our own day. This may give some idea of the expanse of time which Egyptian history covers. Yet Babylonia was already civilised when Egypt was inhabited by Neolithic savages. At least, so Dr. Budge's conclusions would seem to show.

Many interesting hints are given by Dr. Budge as to the relations between the Egyptians and the peoples of Southern Palestine from the fourteenth century B.C. onwards. He discusses the question of the Exodus very fully, and describes the rise of the Jewish kingdom after the final withdrawal of Egyptian authority during the time of the *rois-fainéants* of the Twentieth Dynasty. Henceforward the Egyptians merely made periodical raids into Palestine, as under Shishak (950 B.C.) and Necho (600 B.C.), with interludes of Assyrian and Ethiopian invasion and conquest of Egypt itself, which now had sunk to the position of the proverbial "broken reed, upon which, if a man lean, it shall pierce his hand," and was ripe for the Persian yoke and the Macedonian deliverance, which was to bring Egypt within the fold of Hellenism.

In the preface to the sixth volume Dr. Budge's tone becomes strongly controversial and, we think, righteously so, for he is tilting at a great error which has had widespread and most unfortunate consequences; we refer to the erroneous conjectures of a German Assyriologist, Dr. Winckler, as to the existence of a country in Arabia called Musri, which have formed the foundation of a series of most amazing theories, enunciated by one of "the ablest of the higher critics," as Dr. Budge courteously describes him, Prof. Cheyne, of Oxford, on the subject of the early history of the peoples of Palestine. The first note of warning against these theories and their source, the baseless conjectures of Dr. Winckler, was sounded in a review which appeared in NATURE for June 26 of the present year (vol. lxvi. No. 1704) of the third volume of the "Encyclopædia Biblica," in which publication Prof. Cheyne's theories about his "Jerahmeelites" are enshrined. Quite lately, on September 25 last, a review signed with the initials R. C. T. also appeared in these columns, which dealt specifically with the theories of Dr. Winckler, and proved them errors step by step and point by point. Dr. Budge's preface covers much the same ground as the reviewer's article, but is fuller, and, as was to be expected in a popular work, not so technical in its phraseology. His final paragraph is worth reading, and should finally dispose of "Musri" and his son "Jerahmeel." It is rarely, we should think, that one eminent man of science has felt compelled to write so severely of the work of another as Dr. Budge has written of the Jerahmeel theory; yet we confess we think that Prof. Cheyne fully deserves the castigation which Dr. Budge has administered to him; he should realise that a mare's nest does not necessarily become a "brilliant and inspired theory" merely because a German discovered it. There is too much of this *Bauchrutschen vor Deutschland* among our archæologists and Biblical critics, and Dr. Budge has made a timely protest against the absurd habit.

Dr. Budge does not leave the Hellenistic period of Egyptian history outside the scope of his work. His last two volumes contain a very complete summary of the events of the Ptolemaic period, which should be useful to classical students. So far as we remember, the older histories of Egypt, such as Brugsch's "Egypt under the Pharaohs," Wiedemann's "Geschichte," Erasmus Wilson's "Egypt of the Past," &c., come to a close with the end of the *native* kingdom, with the flight of King Nekhtnebf before the Persians, about the middle of the fourth century B.C., and not long before the coming of Alexander the Great. Dr. Budge, however, does not regard his task as ended at this point, for, as he points out, although Egypt was ruled by Greek kings during the Ptolemaic period, she still remained an independent kingdom, and these Greek kings were Egyptian Pharaohs and nothing else. So he goes on with his tale until the death of Cleopatra and the Roman conquest finally bring the independent career of Egypt to an end.

Astronomers will be interested to note Dr. Budge's scepticism as to the possibility of any very trustworthy data for Egyptian chronology being obtained from astronomical calculations which involve consideration of the "Sothis period" (on Dr. Mahler's methods, for instance), while at the same time he accepts Sir Norman Lockyer's calculations in "The Dawn of Astronomy" of the probable dates of the foundation of various Egyptian temples, based upon a consideration of their orientation. This, however, is a very different matter from juggling with Sothis periods, Set festivals and the like, and the production of

an exact date for Thothmes III. from under your hat. "Astronomical evidence," says Dr. Budge (i. p. 158), "supports the evidence derived from every other source in assigning a remote antiquity to the period when Egyptian civilisation began; but unfortunately it does not assist us in formulating a complete system of Egyptian chronology with exact dates."

Altogether the work is of great interest, and will no doubt prove of use to the scientific student as well as to the lay inquirer; and it is a monument to the industry of its author.

MOHR ON THE DYNAMICAL THEORY OF HEAT AND THE CONSERVATION OF ENERGY.

Die Entwickelung unserer Naturanschauung in XIX. Jahrhundert und Friedrich Mohr. By Ch. Jezler. Pp. 44 and portrait of Mohr. (Leipzig: Barth, 1902.) Price 1.20 Mark.

MOHR, the apothecary and chemist, is a name that will ever be associated with the foundation of the methods of volumetric analysis. Mohr as a controversialist in the domain of speculative geology is not so generally known, and Mohr as a pioneer in connection with the dynamical theory of heat and the doctrine of the conservation of energy is so little known that his writings have had to be rescued from oblivion by the author of the present pamphlet.

The work under consideration formed the subject of a communication to the Society of Natural Science at Winterthur in December, 1900, and while the paper was being prepared for publication there appeared in the *Berichte* of the German Chemical Society for April, 1900, the "Reminiscences of Friedrich Mohr," by Hasenclever, who knew Mohr personally, and who deals more particularly with his correspondence with Liebig. It appears, however, that one of the two most important works published by Mohr in 1837 escaped the notice of Hasenclever, and it is upon this particular work that Herr Jezler more especially bases Mohr's claim for prominent recognition among the founders of modern science.

The pamphlet which has been submitted for consideration is certainly worthy of very careful attention by all who are interested in tracing the history of one of the greatest generalisations in physical science of the nineteenth century. The first section deals with the development of science as a whole, and is to be regarded as a kind of background in which the figure of Mohr is framed. The second part gives the detailed account of Mohr's work with copious extracts from his published papers, some of the early communications to the first volume of *Poggendorff's Annalen* having given the author no little trouble to obtain on account of their scarcity. The general impression which the reader must form is that Mohr's claim to take high rank among the scientific worthies of the past rests on a very much broader basis than has generally been conceded. Passing over the evidence of his many-sided activity in other departments of science, it is unquestionably in connection with the development of the modern conceptions of heat as a kind of motion and of the "unity of forces" (*Einheit der Naturkräfte*) that the greatest interest will be aroused.

In order to fit Mohr into his proper place, the author expands the three scientific achievements of the past century as classified by Haeckel into four:—(1) The doctrines of the indestructibility of matter and energy; (2) the theory of the correlation or unity of natural forces; (3) the establishment of chemistry as an independent science; and (4) the development of physiology and biology and the Darwinian theory. There is, perhaps, scope for criticism in the proposed classification, but it is not essential to the author's main contention whether this scheme be rigidly adhered to or not. It will suffice to mention that under each of the four headings he gives a brief historical *résumé*. The treatment is necessarily very scrappy, owing to the small amount of space which the author has allowed himself considering the enormous field which he has had to cover. It is clear, however from the facts submitted under the heading of "the theory of the indestructibility of force" and elaborated in detail in the second part of the work that Mohr's views were formulated with considerable precision and published some five years before R. Mayer's first paper on this subject in 1842. In chronological order, Herr Jezler therefore names in connection with this generalisation Carnot, Mohr, Mayer, Joule, &c.

A somewhat acrimonious (and unscientific) controversy raged in this country many years ago respecting Mayer's claims to priority. The writer of this notice has not the least desire to stir up the ashes of this dead strife, but admitting Mayer's claims, it is interesting to learn from the pamphlet before us that Mohr himself drew Mayer's attention to his earlier publications and that a correspondence took place in the course of which Mayer wrote:—

"In dem wichtigen und sehr geistvollen Aufsatze, welchen Sie in ihrem neuesten Werke 'Die mechanische Theorie der chemischen Affinitat' zitieren, haben Sie unstreitig die mechanische Warmenlehre ausgesprochen und haben sogar das Wärmäquivalent numerisch zu bestimmen gesucht."

The reference which Mohr makes in this later work quoted by Mayer is to his first paper of 1837, entitled "Ansichten über die Natur der Wärme" (*Annalen der Pharmacie*, vol. xxiv. p. 141). In this same letter it may be mentioned that Mayer claims priority over Joule in the determination of the mechanical equivalent of heat. Mohr's second paper of 1837 is entitled "Ueber die Natur der Wärme," and a quotation from this paper given in the present pamphlet (p. 10) shows that Mohr had fully realised the principle of the "correlation of the physical forces," as it was afterwards called by Grove in his celebrated work bearing this title. The historian of this branch of physical science, Max Planck ("Das Prinzip der Erhaltung der Energie," Leipzig, 1887), in pushing Mohr's claim, appears also to have depended only upon this second paper and to have overlooked the first paper. Reading this contribution now *in extenso* as it is reprinted in the pamphlet, it is remarkable to find how closely Mohr approximated in the year 1837 to the current views held by physicists and chemists. The subject was certainly in the air, but Mohr was apparently too far in advance of the time, for his papers fell into oblivion until he himself reminded his contemporaries of their existence. As is pointed out, however, in the

present lecture, the fundamental importance of the conception of heat as a form of energy was not grasped by the then editor of the *Annalen*. It seems that at first even Mayer's work was more appreciated abroad than in his own country, and the great work of Joule, whose first communication was published in 1843, was not noticed in the *Annalen* until 1848, while his second memoir, published in the *Philosophical Transactions* in 1850, was noticed in *Poggendorff's Annalen* only in 1854. It is not surprising in these circumstances that a writer who failed to enforce his views—although we now know these to have been perfectly sound—by original experiments should not have succeeded in turning the direction of contemporary scientific thought by two philosophical essays which, bearing in mind the date of their publication, were little short of revolutionary. But it certainly is remarkable that his contributions should have been altogether overlooked by later writers who were, and are, fully cognisant of the importance of the doctrines in question. Thus in the list of names given by Father Secchi in 1878, that of Mohr does not appear. In a lecture on the development of the exact sciences during the nineteenth century given by Prof. van 't Hoff before the German Association in 1900, it is pointed out that the law of the conservation of energy, although essentially a physical discovery, was not made by physicists in particular. He mentions Mayer the physician, Joule the brewer, Colding the engineer, and especially Helmholtz, at that time a physiologist. Herr Jezler adds:—

"Warun hier nicht als erster Mohr, ein Apotheker, genannt werden soll, ist mir unbegreiflich. Auf Grund vorliegender Experimentalforschungen (Melloni, 1798 bis 1854) kam Mohr durch Induktion zur dynamischen Warmelehre im Gegensatz zu der gebrauchlichen materiellen Warmetheorie, durch Deduktion gelangte er . . . zur Einheit der Naturkrafte, gleichbedeutend mit dem Prinzip der Erhaltung der Kraft."

Cases similar to Mohr's, in which important new conceptions have been started by men who failed to influence contemporary opinions, are well known in the history of science. Sometimes recognition has come during the worker's lifetime, as with Newlands and the periodic law—which example, by the way, is not referred to by the writer of the present pamphlet, although he mentions several other cases. Generally, however, the recognition is posthumous. As an instance of this we have Waterston's anticipation of the kinetic theory of gases, rescued from the archives of the Royal Society by Lord Rayleigh. When by masterly and convincing treatment some great generalisation which has been in the air for some time previously is finally made evident to the scientific world by the stroke of genius, there is always a danger of reading too much into the works of the earlier investigators and of interpreting their results in the light of later knowledge. The writer of this notice ventures to quote by way of illustration the enormously enhanced reputation of Lamarck as an evolutionist since the publication of the "Origin of Species." Is it going too far to say that Charles Darwin has made the reputation of Lamarck? In the case with which we are immediately concerned, however, a candid examination of the evidence will, we believe, show that Herr Jezler has not credited Mohr with more than was due to him.

R. MELDOLA.

SOIL SURVEYS.

Field Operations of the Division of Soils, 1900. By Milton Whitney, Chief (U.S. Department of Agriculture). Pp. 474 + a case containing 24 maps. (Washington, 1901.)

PERHAPS one of the greatest services which the scientific man can render to the agricultural community in any country is the classification of the soils into certain types, defined by their chemical or physical properties, and the allocation of these types to their appropriate areas, so as to obtain a soil map of the district in question.

Despite disturbing factors, certain types of soil persist over wide stretches of country and are characterised by a general physical and chemical resemblance, and also by a corresponding similarity in natural flora, appropriateness to particular crops and responsiveness to certain kinds of manure. The constancy of these soil types is the result of a common origin from the same kind of rock, and the difficulty lies less in recognising the type than in tracing its boundary line.

As a fundamental basis comes the geological survey, particularly the "drift" maps showing the superficial deposits due to running water, ice, &c., which, though of no great geological importance, are the origin of the soil proper. But for the purposes of a soil survey a little more than even a "drift" map is wanted; further subdivisions must be introduced to show changes in soils on the same formation due to variations in the lithological character of the formation, or those due to the sorting action of water in the case of soils of transport.

These variations, in fact soil classification generally, must be based upon physical structure, must amplify and give exactitude to the practical man's division into clays, loams and sands; the chemical properties of the soil may vary concurrently, but are too much subject to casual change to serve as prime means of distinction. As an instance, the upper beds of the Lower Greensand in east and mid Kent give rise to rich loams, on which many fine hop and fruit plantations are situated; further west the formation gradually changes, until in west Surrey and Hampshire it is barren heath land the soil of which is alike wanting in the finer "clay" particles, carbonate of lime and the soluble salts which go to feed the plant. Again, in the book under notice many examples will be found of two or more distinct soils of the same origin, *e.g.* the maricopa soils (p. 302), described as consisting of "colluvial materials . . . largely granite . . . divided into four soils, depending upon the degree of comminution of the rock."

The volume before us represents a year's work of the Division of Soils of the United States Department of Agriculture in this particular direction of constructing a series of soil maps; twenty-four of the maps are given on a scale of 1 inch to the mile, and show, by a system of colouring similar to that of a geological map, the type to which the soil belongs. The accompanying text gives a mechanical analysis of the type soil, *i.e.* its division into fractions each consisting of particles of a certain size, and in some cases a chemical analysis, also such information collected on the spot as the distance to ground water, climatic features, characteristic crops or natural flora and other local economic conditions.

It was found, according to Mr. Whitney's preliminary review,

"that it was quite possible to map these soil areas independently of the geology of the area, or the exact chemical or physical character of the soil; that the proper course was to construct maps in the field, showing the area and distribution of the soil types; to explain as fully as possible from geological considerations the origin of the soil and to leave the soil chemist and physicist study the differences. The fact is recognised that these chemical and physical properties of soils are so complex and difficult that it may take many years to explain them through laboratory investigation; but, pending this complete investigation, the maps themselves will be of the utmost value to agriculturists in indicating the areas over which certain soil conditions are found to prevail. . . . The recent successful growing of Sumatra tobacco on a certain soil in the Connecticut Valley is a very striking instance of the possibilities growing out of the detailed soil survey in any given locality."

The whole work is an excellent example of the thoroughness with which America carries out her State services; the maps themselves are clear and distinct; some of them, like the Saint Ana (California) sheet, represent a very complex distribution of soils, the survey of which must have involved no light amount of field work, while the accompanying text is most liberally illustrated with analyses, sketch maps and sections, and photographs illustrative of scenery, crops or vegetation, the ease with which photographic illustrations are now produced being perhaps responsible for the trivial nature of one or two of the objects selected.

Several of the sections of the survey deal with that interesting factor in all arid or semi-arid areas, the existence of alkali soils and their extension under irrigation, which is, unfortunately, almost the only method of farming possible. Alkali is used in a generalised sense as indicating any predominance of soluble salts, generally sulphates and chlorides of sodium, magnesium and calcium, in the ground water, so that vegetation is destroyed or restricted to certain "salt" plants, and on occasion the salts effloresce in a white powder on the surface. Sometimes carbonates of the alkalis are also present, which by their injurious action upon the texture of the soil and their solution of the humic acids give rise to "black alkali" spots, more dreaded even than the white. These "alkalis" probably represent nothing more than the normal products of the weathering of the fundamental rock minerals, but owing to the limited rainfall there is no percolation through soil and subsoil, to wash everything soluble into the rivers. Instead the salts remain in the subsoil, and irrigation, by raising the level of the ground water, may easily bring the salts so near the surface that they rise in the capillary water to the surface and there are crystallised out. An instance of the damage due to careless irrigation and the rise of the subsoil water is given in the report before us in the account of the Salt River Valley, Arizona.

The phenomena of alkali soils and their increase through irrigation are neither new nor confined to the United States; any arid climate where the products of weathering are not removed in the "country drainage" shows the same problem. Our irrigation engineers in India and Egypt are regularly confronted with the problem, for which there is only one solution, underdrainage so that the cultivated soil may be washed from time to time, and careful cultivation to minimise all evaporation from the soil except through the leaves of the crop. But though the "alkali" problems are common in the old world, it has not been until the time of Hilgard, Whitney and the present Division of Soils in the U.S. Department of Agriculture that we have had any real knowledge of their composition, or any study of the physical and chemical principles underlying the movement of the injurious material in the soil.

The character of the information provided by a soil survey must largely depend upon the nature of the country; in many parts of the United States agriculture is so recent that there is no accumulation of experience as to suitable crops, hence the survey, by comparison of the texture of the soil, the climatic features, depth to ground water, &c., with the conditions prevailing in known areas, can directly advise the settler with what crops he is most likely to succeed.

But in a country like our own, the land has been under cultivation so long that a great mass of local information, based upon experience, exists as to the character even of individual fields. Hints as to methods of cultivation or cropping based upon analysis are likely to be too general to be of any service; the chief application is rather the information that can be afforded as to the use of manures, for enormous economies could still be effected in the manure bill of nearly every farmer who buys artificial manures, if they were properly adapted to his soils and crops.

In Britain, the great initial want is the publication of drift maps of the Geological Survey on the six-inch-to-the-mile scale; were this in existence, it could be rapidly supplemented by the work of the local agricultural colleges until every farmer could be put in possession of that exact knowledge of his soil which is fundamental for all farming operations.

A. D. H.

AN ADVANCED TEXT-BOOK OF BOTANY.

A University Text-book of Botany. By Douglas Houghton Campbell, Ph.D. Pp. xv + 579. (New York: The Macmillan Company; London: Macmillan and Co., Ltd.) Price 17*s.* net.

THERE are probably few books that are much harder to write than those which endeavour to deal, within a limited space, and from the point of view of the needs of the advanced student, with the whole range of any extensive branch of science. And indeed it is perhaps doubtful whether the time has not gone by when such works can hope to lay claims to much educational utility. Certainly this is the case as regards botany, which now covers so wide an area of knowledge that a bulky volume would be required merely to indicate in outline the more salient facts and their general connections and bearings.

The impression seems to be gaining ground that, for students of university type at least, a better method of treatment lies in the endeavour to expound on more truly scientific lines the facts embraced in its smaller subdivisions rather than in an attempt to range over the whole science in the course of a few hundred pages. And we think this modern tendency is a good one. The student who is hurried over so large a field of knowledge

can hardly hope even to scratch the surface, much less seriously to cultivate any part of it. He certainly will not receive that kind of training which goes to form a critical judgment on facts and inferences, although the imparting of this ought to be one of the chief objects of all higher education, whether of a scientific character or otherwise. It is this conviction that obliges us to confess that we think Prof. Campbell has set himself a difficult—if not, indeed, an impossible—task, and we cannot avoid a feeling of regret that he should have decided at all "to present in as compact a form as possible an outline of the essentials of modern botany." It is not that the book is not good of its kind—of which many already exist—but we doubt the intrinsic usefulness of its aims, even admitting these to have been realised. At any rate, the results, in so far as taxonomy, morphology and physiology are concerned, are certainly disappointing. The information given is of necessity ofttimes scrappy, and especially is this the case in the chapters dealing with classification. The student would scarcely find any other use for them than as mere statements to be learnt by heart. He would assuredly experience frequent difficulty in ascertaining on what rational basis the systems of classification themselves are erected.

By far the best part of the book is that devoted to a consideration of the geological and geographical distribution of plants. It contains much excellent matter, and may be heartily commended to students. Perhaps one might be inclined to take exception to a statement here and there, as, for example, the assertion that man is a very necessary agent in effecting the wide tropical distribution of the coconut.

But if our judgment on the book regarded as a whole appears to be a somewhat adverse one, this is not due to the way in which Prof. Campbell has executed his self-imposed task; our quarrel lies rather with the nature of the task itself. Nevertheless, the book, considered as a work of reference rather than as a text-book for the average student, may probably prove decidedly useful. It appears to contain very few errors, and the figures are numerous and, on the whole, excellent.

EMBRYOLOGY OF THE LOWER VERTEBRATES.

Lehrbuch der vergleichenden Entwickelungsgeschichte der niederen Wirbeltiere, in systematischer Reihenfolge und mit Berucksichtigung der experimentellen Embryologie bearbeitet. By Prof. Heinrich Ernst Ziegler. Pp. xii + 366; 327 figures and a coloured plate. (Jena: Gustav Fischer, 1902.) Price 10 marks.

THIS volume marks the tendency to increased specialisation in text-books, for it is an embryology of *the lower Vertebrates.* It also fills an obvious gap, for Balfour's classic work is acknowledged to be out of date, the large cooperative treatise now being edited by O. Hertwig is on an altogether bigger scale and different plan, the works of Bonnet, Kollman, Minot and O. Schultze deal with man or with mammals, and even in the well-known text-books of Hertwig and Milnes Marshall the lower Vertebrates are somewhat overshadowed by their successors, the Amniota. Thus there is room for Prof. Ziegler's volume, at which he has laboured, he tells us, for a dozen years. The result seems to us to justify his carefulness.

We would first remark on some of the distinctive features of the book as a whole. (1) Most attention is paid to the earlier stages in development; thus gastrulation and germ-layer-formation have more space than organogenesis. (2) While prominence is given to morphological ideas, the salt of which does not lose its savour, much attention has been paid to the trustworthy results of recent work in experimental embryology. (3) In regard to some of the more important moot points, the author gives a just statement of conflicting interpretations; in regard to others, he frankly states that he has given prominence to the view which his own investigations have led him to confirm or to formulate. (4) Very useful to the student are the numerous foot-notes which define the more difficult technical terms as they occur in the text, and sometimes include little side excursions of pleasant interest. (5) The bibliography at the end of each chapter is very full, but it has been put through a sieve, and, to avoid needless repetition, much of the older literature (given in Balfour's "Embryology," &c.) has been omitted. (6) There is an illustration on almost every page, and while there are many old friends (only eighty-seven from other text-books), seventy-four are Ziegler's own.

The first chapter gives recipes for preservation, and hints as to sectioning, model-reconstruction (of which the author's father was one of the pioneers), photography and the like. In the second chapter, there is a general sketch of the development of Vertebrates, with an exposition of technical terms. Perhaps the most interesting section is that in which the developmental processes in the foundation of organs are summarised: cell-movements; differentiation; unequal growth; curvature, folding and tube-formation; evagination and invagination, formation of villi and diverticula; proliferation; and splitting. Emphasis is laid on the familiar but difficult distinction between palingenetic and cœnogenetic processes, and it is further noted that complications arise by what may be called temporal and spatial shuntings (Heterochronien und Heterotopien), when an organ of increasing importance appears more and more precociously, *e.g.* the heart in Amniota, and when the seat of formation is altered, as in the shifting of the Blut-Anlagen from mesoderm to endoderm in Amphibians.

The succeeding chapters, forming the body of the book, deal with the lancelets, Cyclostomes, Selachians, Ganoids, Teleosts, Dipnoans, Amphibians and Gymnophiona; and the last chapter, on the Amniota, shows how the development of the lower Vertebrates sheds light upon that of the higher. We find these chapters lucid and interesting; the material is freshened, if not as yet greatly illuminated, by the incorporation of the experimental results; the notes (at the head of important sections) on the most essential memoirs and on demonstration-material will be of service to other teachers; and there is a fresh, stimulating atmosphere about the whole book. In evidence of its up-to-dateness, we may note that it includes the work of Dean on Bdellostoma, Graham Kerr on Lepidosiren, Brauer on Hypogeophis, and so on.

A brief indication may now be given of the author's

attitude to various general problems. It is, on the whole, conservative. His embryological studies leave him more than ever convinced of the unity of the Vertebrate phylum; the different modes of cleavage can be readily unified, but there seems no doubt that the discoidal mode has arisen several times independently; the processes of gastrulation (archi-, amphi- and disco-gastrula) can also be unified as Haeckel maintained; the two ways in which the medullary canal arises are connected by transitions, *e.g.* in Lepidosiren; the neurenteric canal, which had originally a nutritive significance, is another unifying character; and so on. It is more difficult to give a unified account of the mesoderm, which may arise by pouching, by splitting off, or by a proliferating process. "But," as the author says, "one cannot ignore the fact that all the modes of formation which occur in Vertebrates are connected by transitional stages." Against the prevalent view that the mode of origin by pouching, familiar in Amphioxus, is primitive, Ziegler maintains that the Vertebrate mesoderm arose originally as a proliferation on each side of the blastopore-margin, and subsequently spread forwards along the dorsal wall of the archenteron. In spite of some objections, which are not ignored, the author remains a firm adherent to the doctrine of the distinctiveness and "specificity" of the germinal layers—"one of the most important results of embryological research." In his concluding words, the author expresses the mood of the whole book when he says that embryology is luminous only in the light of the evolution-idea.

J. A. T.

TWO BOOKS ON AMERICAN SPORT.

The Deer Family. By T. Roosevelt and Others. Pp. ix + 334; illustrated.

Salmon and Trout. By D. Sage and Others. Pp. x + 417; illustrated. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1902.) Each volume 8*s.* 6*d.* net.

BOTH these works belong to the "American Sportsman's Library," of which Mr. C. Whitney is editor, and both fully maintain the high standard of excellence set by their predecessor in the same series, "Upland Game Birds." President Roosevelt, whose name appears first on the title-page of the volume on deer, is an excellent type of the best class of naturalist sportsmen, and of his three coadjutors Dr. D. G. Elliot, who writes on caribou, is a zoologist of high reputation, while Mr. A. J. Stone, who treats of the moose, is a famous Alaskan explorer and field-naturalist. Mr. Roosevelt, who contributes a thoughtful introduction to the volume, describes the deer of the Rocky Mountains and Eastern America as well as the prong-horn antelope; while the deer of the Pacific coast fall to the lot of Mr. T. S. Van Dyke. The only disadvantage we see in this arrangement is that the mule-deer is described twice over.

In his introduction, Mr. Roosevelt refers to the different views entertained as to the number of distinguishable forms of American deer and their nomenclature, but sums up by observing that there are only six wholly distinct kinds, the moose, the caribou, the wapiti, the whitetail, the mule-deer and the blacktail. With this philosophical view we are thoroughly in accord, and if all zoologists would but agree to regard these, and these only, as *species*, the subject would be much simplified. It is satisfactory to note that Dr. Elliot takes practically this view in his chapter on the various local forms of caribou. In consequence, apparently, of the divergent views prevalent in regard to nomenclature, Mr. Roosevelt very wisely avoids scientific names altogether, although such names do appear on the valuable maps showing the range of each species, which have been contributed to the work by Dr. C. H. Merriam.

The great decrease which has taken place of late years in the numbers of American big game is deplored by Mr. Roosevelt, who nevertheless urges that if proper game-laws be enacted and adequately enforced and "sanctuaries" established, most or all of the species may be preserved for many years to come. The professional skin and trophy hunter is the man who does most harm to big game, and next to him the "big-bag" sportsman, who receives a severe "slating" at the hand of the President.

Limitations of space forbid any detailed notice of the text, and it must accordingly suffice to say that in the case of each species attention is very fairly divided between the natural history and the sporting aspects of the subject; in fact, the whole volume is just what a work of this nature ought to be. The authors have been specially fortunate in their artists, among whom the name of Mr. C. Rungius occupies the post of honour. Among the numerous full-page illustrations in the volume, the one that most takes our own fancy is that of the Colorado mule-deer, or blacktail. It may be added that Dr. Elliot (p. 268) authenticates, by reference to an old sporting work, the statement (recently discredited by an American writer) that caribou formerly crossed from Newfoundland to the mainland on the ice.

The second of the two volumes is written on somewhat more technical lines than the first, the writers giving full lists, with the scientific names, not only of the species, but likewise of the subspecies of the salmon group. The first section of the book, by the author whose name is mentioned with the title, is exclusively devoted to the true salmon, which is common to both sides of the Atlantic. Unhappily, from want of due protection, this noble fish has been practically exterminated from the rivers of the United States, and, in the author's opinion, it would take ten years to fully restock them. On the other hand, "the British Possessions in North America undoubtedly afford the greatest field for the salmon angler of the future in any part of the globe." As Mr. Sage is a practical and observant fisherman of many years' standing, his remarks on the vexed question whether salmon feed while in fresh water are deserving of attention. His opinion is that they do, and his explanation of the fact that they are so seldom caught, even in the sea, with food in their stomachs is that they are in the habit of disgorging when threatened by danger. Several instances are cited of salmon seizing objects of considerable size with the apparent intention of swallowing them.

The ugly though valuable Pacific salmon of the genus Ogmorhinus, which often occur in such myriads in Alaskan waters and afford almost the whole of the world's supply of tinned salmon, are described by Messrs. Townsend and Smith, by whom five species are

recognised. Pacific salmon received the attention of fish-breeders at a comparatively early date; and, on account of extensive fishing and the pollution of many of the rivers, it is mainly owing to artificial propagation that the supply of these fish is maintained on the western sea-board of the United States.

The description of the numerous forms of trout and charr met with in the fresh waters of North America falls to the lot of Mr. W. C. Harris, and constitutes (inclusive of the angling notes) more than half the contents of the volume. The author divides these fishes into salmon-trout (commonly called brook-trout in America) and charr-trout. That all the latter are specifically, if not generically, distinct from the true salmon there can be no doubt, although it has yet to be proved that this is the case with the members of the former group. On this point, however, the author is silent, although he admits the extreme difficulty of classifying these fishes in a satisfactory manner.

"The most prominent external marking by which the salmon-trouts and charrs may be distinguished apart," writes the author, "is the presence of red or crimson spots on the body, the only exceptions being the great lake trout, with greyish markings, and the Arctic trout (*Salvelinus arcturus*), upon which no reddish spots have been observed."

It was owing to the absence of these red markings that the great lake trout, which now typifies the genus Cristivomer, was formerly regarded as a true trout instead of a charr.

In addition to being a practical guide which should be in the hands of every angler in American and Canadian waters, this excellent little volume is a valuable manual of North American Salmonidæ. R. L.

GAS ANALYSIS.

Methods of Gas Analysis. By Dr. Walther Hempel. Translated from the third German edition and considerably enlarged by L. M. Dennis. Pp. xix + 490. (London: Macmillan and Co., Ltd., 1902.) Price 10*s.* net.

THE value of this well-known handbook on gas analysis has been increased by additions both by the author and translator, so much so that those who already possess a copy of the first English edition will probably consider it necessary to obtain also the present one. The original work was practically restricted to a description of operations which could be carried out with the apparatus devised by the author, and this character is still retained. The slight incompleteness thus entailed is more than compensated for by the extremely practical nature of the instructions; every process described has been thoroughly tested and will work. The author has found it advisable to abandon the division into technical and exact gas analysis because, as he states in the preface, apparatus originally intended for technical purposes may advantageously be employed for many purely scientific investigations, and, on the other hand, technical analyses must often satisfy the most exacting conditions as to accuracy. The chief additions to the first edition comprise new methods for exact gas analysis and for the determination of combustible gases, the separation of argon from the atmosphere, improved methods for the determination of carbon monoxide in gas mixtures, the analysis of acetylene gas, the examination of gases produced by living bacteria, the simultaneous determination of fluorine and carbon dioxide, the determination of the heating power of gases, the estimation of sulphur in organic bodies and of carbon in steel, and the analysis of the gases evolved in the electrolysis of chlorides and the manufacture of bleaching powder. The method originally adopted by the author for the exact analysis of gases, although accurate, was somewhat cumbersome to work and expensive to set up. By adopting the principle of a compensation tube, slightly modified from the suggestion of Pettersson, the apparatus assumes a very practical form, gaining in convenience and cost without loss of accuracy. The determination of the heating value of gas, a determination which is rapidly increasing in importance on account of the extended use of gas for heating and power purposes and in the Welsbach incandescent burners, has been usually carried out in calorimeters of the Junker type. These are costly, require considerable amounts of gas, and must be carried to the place where the gas is being used. In the ingenious apparatus described by Prof. Hempel, a heating value can be determined on two litres, so that samples of gas can be brought from a distance in metallic receivers and examined in the laboratory.

In the analysis of combustible gases, it is shown by the translator that a modified Coquillion pipette, in which the combustion is carried out by an electrically heated platinum spiral, may in many cases advantageously replace the usual explosion method. The error due to the partial combustion of the nitrogen is avoided, and owing to the use of oxygen instead of air much larger quantities of gases can be burned with a corresponding gain in accuracy, numerous test analyses being given in proof of this point. The only suggestion which can be made as to additions to this chapter is an investigation as to the possible errors introduced into indirect explosion analyses by the deviations of the various gases from Boyle's law. According to Prof. Leduc, the errors from this cause may amount in special cases to as much as 3 per cent. when the gases are measured at constant volume. In the determination of carbon monoxide, a large amount of space, some twelve pages, is devoted to a description of the hæmoglobin method, whilst the method of C. de la Harpe and Reverdin, in which the monoxide is burnt by contact with iodine pentoxide, is dismissed with a short mention, although this method has been shown by Nicloux, Gautier and others to be at least as sensitive as the most refined modification of the blood reaction, and is also applicable to coal gas. As it seems probable that this method will supersede the doubtful cuprous chloride method, it would appear to have been worthy of a more detailed examination. In this case, as in others in which criticism might be offered, the author has preferred to give prominence only to those methods with which he has had personal experience. The work as a whole is a most valuable addition to the very limited number of works dealing with the handling and analysis of gases.

G. N. H.

THURSDAY, NOVEMBER 13, 1902.

THE BUTTERFLIES OF THE BORDERLAND BETWEEN NORTH AND SOUTH AMERICA.

Biologia Centrali-Americana. Insecta—Lepidoptera—Rhopalocera. Vols. i. and ii., 1879-1901. Pp. xlvi + 487 + 782. By Frederick Ducane Godman, F.R.S., and the late Osbert Salvin, F.R.S.

WE often hear, and are unfortunately compelled to admit, that the claims of learning are far too much neglected in our country, and that the wealth which is accumulated so much faster than in past times is but rarely under the control of men inspired as were the "pious founders and benefactors" of old. With humiliation and some perplexity we are forced to recognise that in younger lands the ancient spirit is as strong as it has ever been in history. Modern conditions have nothing to do with the indifference to learning exhibited by the average wealthy Englishman; for wealth is brought together under the newest of new conditions in the countries where it is lavishly spent in establishing and maintaining the centres of learning. And this is not only true of the most recent of Colonial and American universities. The older American universities date far back into colonial times. The life of Harvard as a university of an independent Power is even now shorter than its life in a British Colony; and yet Harvard, Yale and the other older American universities yearly receive benefactions for which Oxford and Cambridge look in vain. The needs of both Oxford and Cambridge are widely known in the country, as well as the serious lack in efficiency which both of them suffer for want of an assistance which on the other side of the Atlantic would be freely given. The difference in spirit seems to lie in a glorious "fashion" formerly dominant and powerful, but at present weak and enfeebled, in this country while it reigns supreme elsewhere. Such an interpretation is hopeful; for fashions may, and often do, revive, and even surpass, their former influence. All honour to those who in these latter days have helped on the good work in our land. Among these noble efforts on behalf of learning a prominent place will always be assigned to the munificence which has placed the investigation of the biology of Central America to the credit of British science.

The great work of which an important section forms the subject of the present article is now drawing to its close. It is, therefore, not inappropriate to say something of the biogeographical area of which the plants and animals are described in this vast monograph, or rather series of monographs, and to attempt to ascertain the reasons which induced F. D. Godman and the late Osbert Salvin to make the choice of their life-work.

However they may be divided and named, the life-bearing land-masses of the world are essentially arranged as an incomplete ring girdling the Arctic Ocean and sending three great extensions towards the south. P. L. Sclater's original classification of the zoological regions of the south, which has never been equalled by any of the later suggestions and would-be improvements, divides the northern ring into two regions, an Old-World segment and a New. It is admitted that this division is chiefly adopted for the sake of convenience and not because of any great difference between these two sections. The faunas of the three southern extensions differ widely from each other and also from those of the Holarctic belt. Interest is therefore concentrated on the point of junction between each southern extension and the northern ring, which more or less directly connects it with the two other extensions. The Ethiopian land-mass is cut off from the belt by a vast desert area. The most peculiar and interesting southern parts of the Indo-Australian mass are cut off by sea, the nearer less peculiar part by the most mighty mountain range in the world. There remains the Neotropical extension, in certain groups the most peculiar of the three, in species probably the richest, and, unlike the others, freely connected with the northern belt, the desert barrier penetrated by continuous north-and-south-running mountain ranges. Free continuity at no very distant period is in this case also proved by the reappearance of characteristic northern genera on the temperate southern Neotropical mountain ranges, such forms being wanting from the corresponding Ethiopian mountains. Furthermore, the east and west ranges of the Old-World part of the belt form barriers against which many plants were driven and exterminated by the advancing cold of the Glacial period, while in the New World the same species were able to escape southwards and return when the period came to an end.

From these considerations it is obvious that the point of junction between a south-extending land-mass, as peculiar as any of the three and far more freely continuous with the north than any other, is the most interesting and critical region in the world, and one which was bound to throw most light upon the problems of distribution. The vast importance of the thorough working out of this transition area Godman and Salvin had the genius to seize upon, as the result of their first visits, singly or together, in 1857-8, 1859-60, 1861-3—early days, when the "Origin" had only just appeared and the problems of distribution were first beginning to be attacked. So successful was the investigation, and carried on with such energy, enterprise and munificence, that this area, then obscure and little studied, has become probably better known than any other part of the world which can in any way compare with it in richness. The collections have been worked out by the most distinguished specialists, the descriptions published in the "Biologia," and with splendid generosity the whole material, labelled and complete, has been handed over to the nation, so that for all time the British Museum will be the one place in which the biology of Central America must be studied. Whatever may be true of the political sphere, the Monroe Doctrine of learning has been infringed on so magnificent a scale that any attempt at repair is hopeless, and our American friends will probably find their revenge by annexing biological territory in the Old World.

The completion of the two volumes on the Lepidoptera Rhopalocera of Central America is of especially deep interest. Here, as in the volumes on the bird fauna, we have the labour of the editors themselves, working together as more than brothers until the pathetic death of Osbert Salvin, on June 1, 1898, left the most obscure and difficult

part of this great monograph still unfinished. Three more years were required before the work was completed by F. D. Godman, who speaks of the large amount of help rendered him by the skill and energy of G. C. Champion, and the value of Dr. Holland's excellent book, which would have been a still greater assistance had it become available at an earlier date.

The immense development of the Central American Hesperiidæ, that difficult group which so long delayed the completion of the work, will be appreciated when the number of species, upwards of 550, is compared with the 178 of the New-World segment of the northern belt and the 66 of the Old-World segment. The study of the Pamphilinæ was a special cause of delay, and not only here, but in the whole family, an examination of the male genitalia, requiring the preparation of immense numbers of dissections, was found to be necessary.

"In Thanaos several of the species are absolutely inseparable by external peculiarities, but markedly different in their genital structure."

Such cases are remarkable and interesting, and range with those in which the males, as in many Enploeinæ, have not hitherto been separated except by the wide difference in secondary sexual characters, viz. the conspicuous "brand" on the wings. That species should be separable only by the characters directly or indirectly associated with the reproductive system of a single sex, while these sole differentiating criteria are strongly marked and evident, suggests the possibility of sexual dimorphism, rather than specific distinction, as an interpretation. Carefully conducted breeding experiments upon a few well-chosen examples would be well worth a trial, and would speedily decide beyond the possibility of doubt as to the interpretation of an immense mass of interesting facts of which the discovery is recorded in this monumental work.

Turning to the bearing of this section of the "Biologia" upon the broad principles of geographical distribution—one of the most important aspects of the whole work—it becomes necessary first to define precisely the extent and limits of the term Central America as employed by the editors. The area will be best understood by the enumeration of the following eight component districts:—North Mexico, South Mexico, British Honduras, Guatemala, Honduras, Nicaragua, Costa Rica and Panama. An excellent account is given of the physical geography of each of these divisions, into which, for the sake of convenience, the editors have separated the whole of their area. They find that the butterfly fauna, which includes many specially modified forms, is mainly a northern prolongation of the tropical South American, and extends to Mazatlan on the Pacific side and to a little beyond Ciudad Victoria in Tamaulipas on the Atlantic, although some purely tropical genera (Eutresis, Scada, Hetæra, Ithomeis, &c.) do not extend north of Nicaragua, Costa Rica or Panama. The Atlantic slope to as far south as Costa Rica has a more abundant rainfall, a more luxuriant vegetation and an immensely richer butterfly fauna than the Pacific, the difference being especially marked in Ithomiinæ, Erycinidæ, Thecla, Papilio, &c.

While the southern forms extend northwards over the coast areas, the Holarctic fauna presses southwards along the high central plateau into Mexico and to some extent even to Guatemala, where the northern genera Argynnis, Vanessa, Limentis and Grapta are met with, and various northern species of Colias occur. On the higher levels, no strictly Alpine forms are found, the insects above timber-line being mostly stragglers from below, while the highest forests are peopled, as in corresponding Andean localities, with species of such genera as Euptychia, Archonias, Catasticta, Pereute, Enantia, &c.

From the account given above, it is clear that the boundary between the northern belt and southern extension takes, roughly, the form of an attenuated U with its concavity directed toward the north. It has already been stated that no two regional faunas in the world are more unlike than the Holarctic and Neotropical. Their extraordinary differences can only be explained by geographical separation for an immense period. At length occurred that "psychological moment" in the organic history of the world when the boundaries fused together and the two contrasted faunas were geographically free to contend and to intermix. The insight of Godman and Salvin led them to investigate the one tract of the land surface of the globe which tells us most of the results of such a struggle. The main conclusion which is impressed by the vast array of facts in the "Biologia" is that stated by Darwin in the "Origin," viz., the predominance of the organic over the inorganic environment of living beings. By the "long results of time," in other words natural selection operating for a vast period, the northern fauna as a whole has been adapted to one environment and the southern fauna to another; and when the two are at length free to invade and to intermix, very little invasion and intermixture occurs. Each fauna is "an army of all arms," as Rolleston used to express it, strong enough in its own territory to repel the attacks of the other. The metaphor is an exceedingly good one, in that it emphasises the truth that each species of the whole fauna (and flora) is not only adapted to its inorganic environment, but also to countless other species of the fauna and flora of the same region. The U-like shape of the boundary line between the two regions expresses the fact that the northern forms gain advantage in the cooler higher ground, the southern in the hotter low-lying coast areas. The occurrence of northern genera on high ground towards the south of South America can best be explained by oscillations of level and changes of climate along the north-and-south-running mountain ranges, which have given northern forms an advantage over the southern and enabled bands of immigrants to press southwards until they reached a latitude to which they were permanently better adapted than the Neotropical fauna. Further changes of level and climate would then rapidly ensure the extinction of such species in tropical latitudes, so that the southward-extending bay of the U-formed boundary in the north and the colony of mountain forms cut off in the south remain as the only evidence of invasion.

The impression made upon the north by invaders from the south is doubtless far stronger, chiefly because the northern fauna being so much poorer the successful invaders make up a higher proportion of the whole. One marked result of successful invasion is certainly seen in the 178 species of Nearctic Hesperiidæ as against the

66 Palæarctic, the effect being doubtless mainly due to that exceptionally strong power of flight to which the authors attributed the unusually wide distribution of butterflies belonging to this family. Other still more interesting intruders are the great Danaine butterflies, of which *Anosia plexippus*, the "Monarch," is the best known and the widest ranging, inasmuch as it extends far into Canada. The peculiar interest of these settlers lies in the fact that certain species of the Holarctic fauna have been profoundly modified into mimicry of them, thus proving beyond the possibility of doubt that the invasion is no new thing—like the spread of the great Danaine *plexippus* into the Philippines, the Fijis, Australia, Hong Kong, &c.

The whole of the vast mass of material in these and the great series of companion memoirs is a remarkable testimony to the insight of P. L. Sclater in drawing the outlines of his regions, of Darwin in laying down the principles of geographical distribution in the "Origin," and of Wallace in his masterly development of the subject in his great works on the geographical distribution of animals. These principles have been tested by an appeal to the facts collected with consummate skill and care from the most critical area in the world, and assuredly they have not been found wanting.

The work is printed and brought out in the same beautiful and costly style as the rest of the series. It contains 112 plates, with more than 2000 admirably executed hand-coloured figures representing 1250 species, and nearly 550 uncoloured figures of the structural parts of butterflies.

The total number of species of Rhopalocera recognised in Central America as here defined is 1805, as against 642 in the New-World and 716 in the Old-World segment of the Holarctic belt. Of these 1805, 360 (almost exactly one-fifth) are described as new. A valuable table of genera shows distinctly and at a glance the relative numbers of the species in each of the eight districts of Central America, in South America, in North America and in the West Indies. The extraordinary poverty of the fauna of the latter is well brought out by this comparison.

The classification adopted is mainly that of H. W. Bates in his paper on the insect fauna of the Amazon Valley (*Journal of Entomology*, ii. pp. 175–185, 1864). The Libytheidæ, instead of being included in the Erycinidæ, are kept as a separate family, represented in the area under consideration by a single species. One slight criticism may be suggested; the monograph begins with the most specialised subfamily the Danainæ, but within the subfamily itself the more specialised group the Ithomiina follows, instead of precedes, the less specialised Danaina.

This vast undertaking has required the cooperation of some of the best living collectors of insects. In addition to the visits of the editors, Mr. G. C. Champion, Mr. H. H. Smith and many others have remained in Central America for long periods of time collecting material for the "Biologia." Great collections, such as those of H. W. Bates and Herbert Druce, have been acquired as a whole and added to the mass of material, which was steadily accumulating for forty years. Wherever Central American specimens could be acquired or borrowed, they have been studied for the purpose of this great work; the single exception was due to the impossibility of receiving the loan of Plötz's quoted but unpublished figures. It is unnecessary to say anything further of a difficulty thus gratuitously thrown in the way of a memorable advance in zoological science, a great gift, not restricted to any single nation, but conferred upon the learning of the world.

The thorough treatment of the more obscure Central American groups and genera is such as to render the work absolutely necessary for the study of the related species in other parts of the world.

It would be inappropriate to discuss the details of this great monograph at any length on the present occasion, but all naturalists should gain a knowledge of the general results, in part briefly discussed in this article, which are lucidly set forth in the introductory chapter. And every naturalist, before he reaches the end of the record of results and conclusions, will feel how deep is the debt that he owes to the research and munificence which have led to so notable a widening of the boundaries of knowledge.

E. B. P.

PRINCIPLES OF DYNAMICS.

Sur les Principes de la Mécanique Rationelle. Par C. de Freycinet, de l'Institut. Pp. viii + 167. (Paris: Gauthier-Villars, 1902.) Price fr. 4.

M. DE FREYCINET first became known to the world as the author of a treatise on dynamics of some bulk and repute, which was published in 1858, and the essay before us shows that at the end of his long and distinguished career of active public life his interest in the subject remains unabated. Referring to his publications during the intervening period, we find two relating to dynamics. In 1887, he communicated to the Academy of Sciences (*Comptes rendus*, cv., pp. 903–910) a note containing the rather interesting suggestion that the term "dynamical capacity" should be adopted in the place of the term "density" as derived from dynamical considerations, on the analogy of calorific capacity; also some proposals about units which were not likely to meet with acceptance. He proposed a standard unit of length derived from the value of gravity at Paris, recommending it by the remark that the length of a pendulum can be measured more conveniently than that of a meridian of the earth. In 1896, he published his essays on the philosophy of the sciences, containing some chapters on mechanics.

The book before us gives the impression of not being up to date, and repetitions from the author's former works which we find in it afford some explanation of this. He does not appear to be well acquainted with the modern literature of the subject. One might expect to find some sign of the influence of Mach, but there is none. The framework of the essay is a constructive sketch of the subject, which cannot be regarded as of much value. It is chiefly interesting on account of the satisfactory tone of protest against *a priori* judgments with regard to the principles of dynamics and on account of some attempts which are made to amend the phraseology of the subject, among which "dynamical capacity" figures prominently. It is disfigured by some inaccuracies and obscurities.

It seems, for example, hopeless to attempt to understand what is meant (p. 86) by the fixity of the sun relative to the earth, which we are told would result from the attraction between the sun and the earth losing its reciprocal character. And the explanation (p. 134) of the mechanical equivalent of heat by the example of the coal consumption required for working an elevating machine, as compared with that required for raising the temperature of water, is not a happy one, even with the addition of a parenthetical reference to unavoidable losses.

The author thinks that there has been too great a tendency among the writers of treatises on dynamics to deal with the subject as a merely abstract science, with but little reference to the basis supplied by the observed motions of actual bodies. But he omits to notice what has perhaps been the most unsatisfactory feature of such treatises, namely, their frequent neglect to deal with the question of the establishment of a base relative to which to measure motions for the purpose of the laws of motion, obscurity thus arising with regard to a fundamental point. Indeed, the book before us affords as good examples as could be found of obscurity due to an attempt to construct statements dealing with the motion of actual bodies without clear specification of the base employed.

In the treatment of dynamics as an abstract science, a base may be assumed at the outset, without any reference to the question whether or how such a thing can actually be identified in nature; but so long as this question is postponed, any comparisons with actual motions are apt to be inaccurate or puzzling. Newton's adoption of the postulate of an "absolute motion," as he called it, stands in the forefront of his statement of the theory. He expounded what he meant by absolute motion sufficiently for his purpose, and for a time his followers were content to accept his statement. But a stumbling block was found in the use of the word "absolute," and this word fell into disuse without any more appropriate terminology taking its place, and thereupon the point in question, instead of taking the first place in any statement of the theory, fell so much into the background as to be in danger of being overlooked altogether. The fact remains that the so-called laws of motion apply only to motions relative to a suitably chosen base, one which is probably connected with other phenomena of physics, but may naturally, and must in the first instance, be regarded merely as a creature of the theory, with no right to a title involving such words as "absolute" or "fixed."

THE DISCOVERY OF JAPAN.

Geschichte des Christentums in Japan. Von Pfarrer Hans Haas. I. Erste Einführung des Christentums in Japan durch Franz Xavier. (Tokyo, 1902.)

IN this large octavo volume of 300 pages, admirably printed at the Rikkyo Gakuin Press, we have the first instalment of what promises to be as full and accurate an account of the discovery of Japan and of the rise, course and downfall of Christianity in that country during the sixteenth and following centuries as the accessible materials render possible. A distinguishing feature is the extent to which native sources of information have been consulted, and though these are neither ample nor very trustworthy, their use lends an interest and an authority to the work which are lacking to the results of previous efforts to present the subject to European readers.

The first notice of Japan was brought to the west by Ser Marco Polo. In a passage pregnant with consequences to East and West, he, or his literary friend to his dictation, writes:—

"Zipangu (Jihpênkwo *anglicé* Jippunkwo, *i.e.* Orient Land) is an island in the high seas lying eastward [of China] . . . . it is of great extent . . . . the inhabitants . . . . are idolaters and independent. And I can tell you that the quantity of gold they possess is inexhaustible . . . . the exportation is forbidden . . . . hence they have an immeasurable surplus of gold."

It is not too much to say that the Venetian traveller's words, scouted in his own day, led to the discovery of America, and to the discovery and temporary Christianisation of Japan. Marco Polo's travels were printed in 1477. What he wrote about "Zipangu" came to the ears of Columbus through Toscanelli, and in 1492 the great navigator sailed westwards to discover the great eastern island about which his contemporaries thought him "extravagant and clean possessed." It was his Ophir, and such he held it to be to the end of his days. Yet the wealth of Japan was a mere fable—even in 1887 its production of gold did not surpass some 500 kilos. It was thus a delusion that led to the discovery of America, or rather prepared the way for that discovery of the Pacific Ocean which proved America not to be a portion of Eastern Asia.

For the discovery of Japan the world had to wait another half-century. It was not the result of design, but indirectly of the division of the undiscovered world by Pope Alexander VI., in 1493, between Spain and Portugal, in return for their armed support of the Roman system—probably the biggest deal the world has seen—and directly of the shipwreck, in 1543, of a Chinese piratical junk having three Portuguese deserters on board on the shores of the island of Tanegashima, lying south of the southernmost point of the island empire. As early as 1508, as Mr. Donald Ferguson has recently shown in his interesting "Letters from Portuguese Captives in Canton, 1534-6," Lopes de Sequeira had been ordered to inquire after the Chijns (Chinese), and in 1517 definite commercial relations were established with Canton. Galvano and Xavier both mention the discovery, but the various accounts, including the Japanese, differ as to time and locality. Nevertheless, it is pretty certain that it took place as above stated, and to this day in Japan "Tanegashima" means a gun or pistol.

But in his famous Peregrinação, Fernão Mendez Pinto lays claim to the discovery as his own—through the mischance also of the Chinese junk, on which he was taking a passage from "Sanchan" to "Lailo" with two companions, being driven by stress of weather to seek shelter off the same island of Tanegashima. Pinto was dubbed by Cervantes the Prince of Braggarts, and our own Congreve uses him as a type wherewith to compare a "liar of the first magnitude." A letter of his own and others of his brethren of the Society of Jesus in which we should expect to find some reference to this exploit

do not mention it, and I agree with Herr Haas that the story is a mere invention.

Of the arrival at Malacca some time in 1547 and of the subsequent conversion by Xavier of three Japanese there can be no doubt, however much we may distrust Pinto's account of his share in bringing about their visit. The chief of the three, Anjiro (Hachiro ?) induced Xavier himself to go to Japan, and in 1549 the great apostle of the east landed at Kagoshima, famous some three centuries later for its stout resistance to an English squadron.

Of Xavier's labours I can say little here. He remained two years and some months in Japan, founded three churches and baptized some 800 converts. Herr Haas speaks highly of his labours. But he seems to have been satisfied with mere external observances, and his ignorance of the language must have reduced his dogmatic teaching to its least expression. What would be interesting and instructive to know would be what the Japanese, especially the Buddhists and Confucianist scholars, thought of his doctrines. No hint has come down to us—perhaps they took no thought of a strange religion that seemed of no great importance. The chapters on the social and political conditions of Japan in the sixteenth century are interesting—particularly the account they give of Buddhism and Confucianism, both in themselves and as a setting to Xavier's apostolate.

Herr Haas's style is not unattractive, and in the eulogy of Xavier rises into eloquence. But—to an Englishman at least—many of the sentences, often occupying half a page or more, are both tedious and obscure. A portrait of Xavier taken from an old print is prefixed, which, however, bears little resemblance to that contained in Dr. Murray's "Japan."

F. V. D.

CHEMICAL PHILOSOPHY.

Le Mixte et la Combinaison Chimique: Essai sur l'Évolution d'une Idée. By E. Duhem. Pp. 207. (Paris, 1902.) Price fr. 3.50.

FROM the earliest times there have existed two opposed views of the constitution of homogeneous mixtures. According to one view, the mixture was in reality as in appearance homogeneous. The elements composing it disappeared as such and were replaced by an entirely new thing, the mixture, from which, however, by appropriate treatment the original elements might be regenerated. According to the other view, the homogeneity was only apparent, and due to the feebleness of our senses. Each element consisted ultimately of atoms, which in the mixture retained their individual character, being mingled, but in no sense fused.

Prof. Duhem in the present essay, which originally appeared in the *Revue de Philosophie*, follows the fortunes and discusses the scientific evolution of these ideas from the time of Bacon and Descartes to the present day. In a series of interesting chapters, he shows the adaptation of chemical theory to facts as they accumulated, tracing the development of the notions of element, equivalent, substitution, type, valence, isomerism. It is, however, to the last chapters that chemists will probably turn with the greatest interest. In these the author gives a critique of the atomic theory and an account of chemical mechanics. His point of view may best be given by quotation.

The great achievement of atomic theory is the simple interpretation of the law of multiple proportions. But, the author asks, is the victory decisive? Who can say that this is the only possible explanation?

"When we see with what simplicity and clearness all the principles of modern chemistry may be systematically expounded, though the name and notion of atom are alike absent, and what difficulties and contradictions arise when it is desired to interpret these principles according to the doctrines of the atomists, we cannot help thinking that the sole success of the atomic theory is only an apparent victory and one without a future, that the theory does not show us the true objective basis of the law of multiple proportions, that this basis still remains to be discovered, and finally, in a word, that the evidence of modern chemistry is not in favour of the Epicurean doctrine."

In a foot-note, the author draws attention to the circumstance that what is here said of the law of multiple proportions and its interpretation by atomic hypotheses may be repeated word for word of the crystallographic law of rational indices and its interpretation either by the integrant molecules of Hauy or the space-nets of Bravais.

With regard to the general aspect of physics and chemistry to-day, the author says:—

"Physical science is not a metaphysic. It has no intention to penetrate beyond our perceptions in order to grasp the essence and ultimate nature of the objects of these perceptions. Its end is to construct by means of signs borrowed from the science of numbers and from geometry a symbolic representation of what our senses, aided by instruments, bring to our knowledge. Once constructed, this representation lends itself to reasoning more simply, rapidly and certainly than the purely experimental data for which it was substituted. By this artifice, physics assumes a breadth and precision which it could never have attained without clothing itself in this schematic garment which we call theoretical or mathematical physics. To each element which logical analysis discovers in any physical concept there now corresponds, not a metaphysical reality, but a geometrical or algebraic character of the symbol which is substituted for the concept. For the notion of a chemical substance, for example, there is substituted a chemical formula; the idea of the analogy of two chemical systems is expressed by a series of equalities between the indices which affect certain letters; the idea of derivation by substitution is represented by means of certain lines or 'bonds'; and the dissymmetry of a geometrical figure serves to represent a substance possessed of optical activity."

We can thoroughly recommend the book for the thoughtful consideration of those interested in chemical philosophy.

OUR BOOK SHELF.

Die Internationalen absoluten Masse insbesondere die elektrischen Masse. By Dr. A. von Waltenhofen. Third edition. Pp. xi + 306. (Brunswick: Friedrich Vieweg und Sohn, 1902.) Price 8 marks.

IN preparing the third edition of this book, the author has, by introducing an amount of new matter, nearly equal to the whole of the second edition, sought to make the work, not only a complete study of the international system of units and measurement, and in particular of the electrical units, but also an introduction to the study of electrical

engineering (Elektrotechnik). In a work dealing with such a subject, we should have thought the publishers would not have departed from the very sensible plan, adopted in practically all good German scientific books, of printing in the ordinary Roman type instead of in the German script. We can safely assert that the adoption of the German character will very considerably reduce the number of foreign readers.

The book is divided into two parts, the first containing chapters on the mechanical, magnetic, electrostatic and electromagnetic units, and a comparison of these two latter systems.

The second part, taking up three-quarters of the book, is entitled "Additions and Explanations" (Zusätse und Erläuterungen), and consists of a somewhat curious collection of all kinds of information and numerical examples, and we are afraid that the reader who uses the book as an introduction to the study of electrical engineering will not profit very much thereby. We think, in fact, that the two objects of the book are incompatible, as it is hardly reasonable to expect a person just beginning to study electrotechnics to grasp such conceptions as the relations of the electromagnetic and electrostatic systems of electrical units, and so forth, or to go from chapter ii. of the second part, on the calculation of dynamos and considerations of the thickness of the insulation on double cotton-covered wires, &c., to chapter iii., introducing, without a word of warning, highly involved considerations of potential theory with differential equations half a page long.

The book will be mainly useful to teachers in technical colleges and schools, who are often called upon for the satisfaction of inquiring students to work out a formula from first principles, a subject with which the practical man has neither the time nor the inclination to bother. Such a teacher would find it useful to have this book by him, and the many references and footnotes given would be additionally helpful in such cases.

In fact, the book appears to us like a collection of notes of theoretical considerations and blackboard examples acquired by a lecturer to assist him in his lectures, and as such will no doubt have its sphere of usefulness.

If we may permit ourselves one more remark, in paragraph 92, on "hydroelectric chains," examples are worked out at length on the calculation of electromotive force according to the old "Thomson" law (equivalence of heat of reaction and electrical current work), and the only warning given that this assumption is both fundamentally wrong and in many cases leads to totally false results is given in a footnote. In a work on "absolute" units, this should hardly occur. The book is indexed very well, which is an additional advantage from the above-mentioned point of view. C. C. G.

Index-tabellen zum anthropometrischen Gebrauche. By Carl M. Fürst. (Jena: Gustav Fischer, 1902.) Price 5 marks.

IN the preparation of their great work "Anthropologia Suecica, Beiträge zur Anthropologie der Schweden," Drs. Gustaf Retzius and Carl M. Fürst had to deal with a vast mass of figures. It is the custom of physical anthropologists, not merely to publish their measurements, but also to give the ratio of a given measurement to another, and this is termed an "index"; for example, the ratio of the breadth of the head to its length is called the cephalic index, and is obtained by multiplying the breadth by one hundred and dividing the product by the length. The calculating of a large number of indices is undeniably a very tedious process, and various devices have been employed to save the student this clerical labour. Certain mechanical and other devices have been invented, but these have never proved satisfactory and are not employed by serious workers. The most accurate and practical rapid method of determining an index is by means of tables which have been carefully computed. It is evident that such tables once constructed and published would materially lighten the labour of those who do this kind of work.

The first tables of this nature were published by Prof. Welcker in the *Archiv für Anthropologie* in 1868. They were calculated only for the cranial index, and even so were not of sufficient range. In 1879, Prof. Flower published some very useful and on the whole accurate tables in his well-known Osteological Catalogue of the Royal College of Surgeon's, London, Part i., Man. These were calculated for the various cranial indices which he employed in that valuable publication; though these tables have proved a great boon to workers, they are not sufficiently extensive to meet modern requirements. Of greater scope are the Broca's tables which were published by Bogdanow in the *Mittheil.* d. kaiserl. Gesells. d. Naturwiss. anth., eth. Abtheil. (Moscow, 1879.) These also had some clerical errors, and the size of the page rendered it somewhat unwieldy. This publication was very difficult to obtain, and as a matter of fact the tables were not generally used by anthropologists.

Now all this is changed, as Dr. Fürst has published his extensive tables in a convenient form and at a low price, and has placed at the disposal of his colleagues, in twenty-nine tables, the result of the enormous labour of Fräulein Ellen Anderson-Gülich, who has made the requisite calculations.

Anthropologists will find in these tables practically all the indices they are likely to require, but there are certain indices which have not been carried sufficiently far to include some of the more extreme measurements that can be made on the living subject of non-European peoples; this will affect but few investigators, and that only rarely. Our hearty thanks are due to Dr. Fürst.

Jahrbuch der Chemie, 1901. Herausgegeben von Richard Meyer. (Brunswick: F. Vieweg und Sohn.) Price 15 marks.

THE Jahrbuch for 1901 is the eleventh of the series, and has for its object a review of the chemical work done during the year. Very few alterations are to be noted in comparison with the previous publications so far as arrangement and scope of the work are concerned. Several changes have, however, taken place on the editorial staff. In consequence of the death of Prof. Märcker, the chapters on agricultural chemistry, technology of the carbohydrates and brewing industries have been relegated respectively to Profs. Morgen, Herzfeld and Delbrück. Dr. W. Küster, of Tübingen, is now the editor of the section on physiological chemistry, and Prof. Doeltz, of Clausthal, of that on metallurgy.

The various authors appear to have given, on the whole, a satisfactory account of the research work carried out in their respective provinces, and the reader will obtain a good idea of what has been accomplished during the past year in both pure and applied chemistry. It seems doubtful, however, whether a compilation of this kind, in which nearly all the collaborators are of German nationality, gives the best possible account of the work of men of science in other countries. The greater part of the researches in pure chemistry carried out by English chemists is published in the *Transactions* of the Chemical Society. The editors of the various sections of the Jahrbuch apparently consider themselves in many cases capable of giving a clear and succinct account of these investigations by reference to the short notes in the *Proceedings* of the Society. It is unnecessary to point out the impossibility of such a mode of procedure being attended with any measure of success, and the practice must be strongly condemned.

It is to be hoped that, in future publications of the year book, greater care will be exercised in rendering an account of the work of English chemists. Its claims to

furnish a faithful review of the most important research work accomplished during the year can only be justified on that condition. H. M. D.

Observations Géologiques sur les Îles Volcaniques explorées par l'Expédition du "Beagle," et Notes sur la Géologie de l'Australie et du Cap de Bonne Esperance. Par Charles Darwin. Traduit de l'Anglais sur la Troisième Edition par A. F. Renard, Professor à l'Université de Gand. Pp. xxii+218; 14 figures, one plate. (Paris: Schleicher Frères, 1902.)

THIS volume is the first part of a French translation by Prof. Renard of the geological portion of the "Journal of a Naturalist," which book, as he remarks in his preface, preceded the "Origin of Species" by fifteen years and shows how surely Darwin had laid in his own mind the foundations for the development of that classic work. We should, indeed, have said that the geological observations proved at what a cost to this science the new birth of biology was obtained did we not remember that the idea of evolution has not only reanimated palæontology, but also has led to a new way of regarding even the inorganic world. Time has not deprived of their value those sections of "Geological Observations" which deal with St. Paul's Rocks, with the fluxional and spherulitic structures in the obsidians of Ascension Island, and with other volcanic islands and the order of eruptive rocks. They, indeed the whole work, can still teach geologists, and not only those who are beginners, the right methods in both observation in the field and the inductive treatment of facts; in a word, how to grapple with new problems. Prof. Renard's intimate knowledge, not only of geology, but also of the English language, so fits him for the work of translation that it is almost needless to say this has been admirably done, and he has added to the value of the volume by including in it the introductory essay which was contributed by Prof. Judd to the volume of the Minerva Library of Famous Books containing Darwin's geological works.

Galvanic Batteries: their Theory, Construction and Use. By S. R. Bottone. Pp. xvi + 376. (London: Whittaker and Co., 1902.) Price 5*s.*

ALTHOUGH the subtitle of this book indicates a comprehensive aim, it is only the construction of primary batteries that receives at all full treatment. In this respect the work is pretty thorough, since the author describes more than 200 different types of cell. The descriptions are short, but are supplemented in many instances by drawings, and should be sufficient to give any reader a clear idea of the essential features of the cell. Data as to the E.M.F., internal resistance and discharge are also given for a fair number of typical batteries. As a handy reference book to which one can turn for information of this sort, this volume should prove very useful, especially, perhaps, to the amateur or to the inventor who is anxious to see if amongst these 200 odd cells there is room for yet one more. From a scientific point of view, the work is disappointing; the tabulation of the different cells is not carried out upon any definite system of classification, so far as we can see, and the theoretical discussion in the first seventy pages is inadequate and unsatisfactory. It is hardly adequate, for example, only to describe the Grotthuss theory (as modified by Clausius) and to speak of this as the "accepted theory of to-day." Again, the fundamental conceptions do not appear to have been clearly grasped by the author, who seems to think that energy and force are the same, and that electricity is a form of energy and may be defined as "a mode of motion in the atoms of bodies." We should not comment upon these errors in a work which is more particularly of a practical character did not the author claim in his preface that "the theory of the battery has been carefully gone into." Should another edition be called for, we think Mr. Bottone would be well advised to omit the theoretical part altogether and confine himself to the careful tabulation of the cells; the information contained in the descriptive part must have needed considerable pains to collect and can hardly fail to prove useful.

The illustrations are, for the most part, clear; there are one or two minor errors, such, for example, as the misspelling of the names of Sir W. Thomson, Latimer Clark and Grotthuss, which we should like to see corrected. M. S.

The Elements of Agricultural Geology: a Scientific Aid to Practical Farming. By Primrose McConnell, B.Sc. Pp. x + 329. (London: Crosby Lockwood and Son, 1902.) Price 21*s.* net.

MR. PRIMROSE MCCONNELL is well known as a shrewd writer on practical farming and as one who has done a good deal to bring the facts of science within the reach of the farming community. The present work is on the fascinating subject of agricultural geology. It has evidently been written *con amore*, and we are told in the preface has occupied the author for many years. He treats first of the origin of soils, then follows a chapter on mineralogy, another on physiography and one on water supply. We then come to the most important section of the book, entitled "Formations and Farming," occupying about 110 pages. The volume closes with a section dealing with the evolution of the present breeds of horses, cattle, sheep and pigs.

The most valuable section, and the one containing most original matter, is that relating to formations and farming. We should much like to see this section greatly expanded and its very various subjects treated in full detail, and the whole accompanied by a good geological map of the United Kingdom, which the present volume, notwithstanding its high price, fails to supply. Such a work would be of standard value. Much of the rest of the volume has apparently been compiled from well-known text-books, references to which are freely given.

To the value of the central section we have already referred, but of the book generally we cannot speak so highly. The book has been loosely written, without much attention to scientific exactness, and hasty statements are from time to time made which require at least serious qualification.

The author views the soil as in every case the chief determining factor of agricultural results, whether relating to crops or animals, and a result is said to follow because the soil is Red Sandstone or Mountain Limestone. The considerable influence of varying climate in a country such as our own is seldom taken into account.

A Teacher's Manual of Geography to accompany Tarr and McMurry's Series of Geographies. By Charles McMurry, Ph.D. Pp. 107. (New York: The Macmillan Company, 1902.) Price 2*s.* 6*d.*

TO teach successfully it is not only necessary for a teacher to have a good knowledge of his subject, but he should also know how best to present its parts to his class, and be familiar, in the case of subjects like geography, with the use to which the common objects of the neighbourhood of the school can be put in rendering lessons clear and interesting. This little book abounds in helpful hints to teachers of geography; it explains how the best results are to be obtained from school excursions, and it should convince the reader that geography is something more than topography, and should be made a means of arousing interest in such subjects as the formation of soils, the cause of scenery, and other changes which are too often ignored in school courses of geography.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Refractivities of the Elements.

IN NATURE for October 16 I drew attention to the relation which exists between the refractivities of the inert gases of the atmosphere and that of hydrogen. Further comparison with the values obtained for other elements shows that the occurrence of simple ratios between the refractivities of allied elements is so frequent as to reduce greatly the possibility that they may be due to chance.

Thus, in the table previously published, there was a gap between krypton and xenon to be filled by an element the refractivity of which should be four times that of hydrogen. This condition is exactly fulfilled by mercury, the vapour of which is also monatomic. The refractivities of chlorine, bromine and iodine are almost exactly in the ratio of 2, 3, and 5, corresponding to those of argon, krypton and xenon; and it is remarkable that the latter trio occupy places in the periodic table which are adjacent to those of the former trio respectively. I cannot find that the value of the refractivity of fluorine has yet been directly determined; but, if there is any law connecting these figures, it should probably bear the same relation to that of chlorine which the refractivity of neon bears to that of argon, *i.e.* $\frac{1}{4}$. It should, therefore, be equal to $\frac{768}{4}$ = 0·192 (H = 0·139).

Again, making allowance for the density of sulphur vapour (96), the refractivity of sulphur is to that of oxygen as 2 is to 1. The following are the figures:—

Element.	Refractivity (Air=1.)	Refractivity (H=·139).	Ratio to H.	Error per cent.
Helium [1] ...	0·1238		$\frac{1}{4}$	−4·4
Neon [1]	0·2345		$\frac{1}{2}$	+0·9
Hydrogen [1] ...	0·4733		1	
Argon [1] ...	0·968		2	−2·2
Krypton [1] ...	1·450		3	−2
Mercury [2] ...	1·893	0·556	4	0
Xenon [1]	2·364		5	+0·1
			Ratios to Cl=2	
Chlorine [3] ...		0·768	2	
Bromine [4] ...		1·125	3	−2·4
Iodine [4] ...		1·920 Violet 2·050 Red	5	0
			(Ratio to O=1)	
Oxygen [3] ..		0·270	1	
Sulphur × 3 [2]		1·629	2	+0·6
Nitrogen [3] ...		0·297		
Phosphorus [2]		1·364		
Arsenic [2] ...		1·114		

The values for Hg, S, P and As were published by Le Roux in 1861 and do not appear to have been verified since. At least, no other determinations are published either by Dufet or by Landolt and Börnstein. Iodine shows anomalous dispersion, and the choice of the value 1·920, which represents the refractive index of the least refracted rays, is arbitrary.

The values for N, P and As do not fit into the scheme, and a redetermination of them would be interesting.

Artificial Mineral Waters.

I THANK you for your kindly notice of my little book in your issue of October 16 (vol. lxvi. p. 602), and I am quite content to leave your reviewer's remarks concerning its blemishes to the judgment of your readers with the one exception of that dealing with the precautions for preventing the contamination of the carbonic acid gas with ammonia. If your reviewer will call to mind the fact that in the generating vessel there is a mixture with an alkaline reaction until the charge is exhausted, he will not consider it as so very astonishing that ammonia may pass into the gas holder. At all events, manufacturers of mineral waters have suffered too much in time past from the presence of gaseous impurities in the carbonic acid gas to permit them to allow the smallest trace of such impurities to contaminate the waters. The conditions of manufacture are such as not to warrant the expectation that either the alkali or the acid in the generator will suffice to hold back traces of either acid or alkaline gases.

WILLIAM KIRKBY.

I UNDERSTAND that Mr. Kirkby objects to the statement I made, in my recent review of his book on "The Evolution of Artificial Mineral Waters," to the effect that precautions to avoid the contamination of the carbonic acid gas with ammonia derived from such traces of ammonium salts as might exist in the sodium bicarbonate employed were unnecessary. In reference to this I would point out that sodium bicarbonate does not decompose ammonium salts under the conditions in question, and that any tendency to become converted into the normal carbonate owing to rise of temperature is effectually checked by the constant production of carbonic acid gas in the liquid in the generator. This is what I meant by saying that the acid used constitutes a sufficient precaution, and if Mr. Kirkby will try the experiment, as I have done, he will find that no trace of ammonia passes from the generating vessel. That manufacturers of foods and beverages should take every possible precaution to avoid the contamination of their products is, of course, highly desirable, but any precautions specially taken for the purpose of avoiding the presence of this particular impurity are, I still maintain, quite unnecessary.

THE REVIEWER.

Light-Therapeutics.

AS a constant reader of your valuable and interesting paper I shall esteem it a favour if any of your scientific correspondents can inform me what is the action of the red rays of light on the hair, and what authority is there for supposing that they have a beneficial effect on the scalp.

In what periodicals, &c., could I find reference to this question?

P. H. BAILY.

Leadenhall House, London, E.C., November 6.

Waste of Energy from a Moving Electron.

IN my last week's letter, I observe some corrections are required. Equation (11); the depth of the shell should be $vdt\,\{1-(u/v)\cos\theta\}$. Equation (13); insert the factor $(1-u^2/v^2)$ on the right side. Equation (14); divide the second term on the right by R.

OLIVER HEAVISIDE.

BRITISH ASSOCIATION GEOLOGICAL PHOTOGRAPHS.

PROBABLY no instrument—not including the bicycle—has more facilitated the labours of the geologist than the photographic camera, which has for some time past become almost as necessary a part of his outfit as the indispensable hammer. Professional and amateur workers alike carry it, and photographs of geological features do increasingly abound. This was already true in 1888, when the happy idea occurred to Mr. Osmund W. Jeffs of forming a public collection of geological photographs, which should be lodged in some central and readily accessible place. As he rightly pointed out, "photographic records of sections and other geological features . . . are not only invaluable aids to geological instruction, but serve also to preserve for future reference the details of many exposures of strata and other landscape features, which in course of time . . . are in danger of

becoming obliterated." At Mr. Jeffs's suggestion, a Committee of the British Association was appointed at the Bath meeting, charged with the duty of obtaining geological photographs, which were to be duly preserved, catalogued, dated and described. The Committee commenced its labours by inviting contributions from all British geologists, and its appeal met with a most generous response. Photographs at once began to flow in, and have continued to do so ever since, so that a vast mass of valuable material is now accumulated in the Museum of Geology, Jermyn Street, which was selected as the home of the collection.

The usefulness of the collection has now been largely increased by the action of the Committee in resolving to publish a selected number of its best photographs, and geologists are greatly indebted to the secretary of the Committee, Prof. W. W. Watts, for the admirable manner in which he has carried this resolution into effect. The success of his efforts is witnessed by the first issue, now before us. It comprises twenty-two photographs, contained in a neat portfolio case; each is accompanied by descriptive letterpress, the date when it was taken and the name of the photographer. The descriptions are terse and to the point, as might be expected when it is added that they are all contributed by well-known geologists; among others, we notice the names of Sir Archibald Geikie, Prof. Bonney, Mr. J. E. Marr and Prof. Watts himself. To show how thoughtfully even smaller matters have been attended to, we may point out that a duplicate copy of the letterpress is provided, printed on one side of the paper only and gummed on the other, so that when mounted each photograph may bear its own description secured to it. Further, in addition to the paper prints, which are platinotype and therefore permanent, there is another

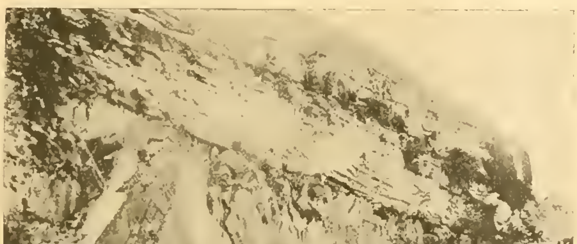

FIG. 1.—Carboniferous Limestone resting unconformably on Ludlow Slates; Arco Wood Quarry, west side of Ribblesdale, about four miles north of Settle, Yorkshire. Photographed by Prof. S. H. Reynolds, 1889. The horizontal beds at the base of the Mountain Limestone here rest unconformably on the upturned and denuded edges of the Ludlow Slates. The latter formed a plane of marine denudation which quickly subsided, causing the absence of mechanical sediments. The district furnishes evidence that many thousands of feet of Lower Palæozoic rock were denuded before the deposition of the Carboniferous strata. An inconstant conglomerate, a few feet in thickness, with pebbles of Lower Palæozoic rock in a calcareous matrix, is found in places, but it is absent in the section photographed. The Ludlow beds are seen dipping south at a very high angle. A marked bedding-plane is seen at the south (left) end of the photograph (above the initials S.H.R.). The more prominent planes visible in the photograph, traversing the slates, are cleavage planes, inclined to the north at an angle higher than that of the bedding. The straight face of the limestone is due to dominant joints. The cliff, from the base of the quarry to the sky line, is many scores of feet in height. JOHN E. MARR.

issue in the form of lantern slides, which should prove of great value in the lecture room.

Where all are excellent it is difficult to choose, and the accompanying photographs, which, with the kind permission of their photographers, we select for reproduction on a reduced scale, are no better or worse than the remainder of the series.

The issue is the first of three, the second of which may be expected to appear before the end of the current

FIG. 2.—Widened joints ("grikes") and rain-gullies in Carboniferous Limestone; Hampsfell, near Grange, Lancashire. Photographed by Mr. Godfrey Bingley. The top of Hampsfell, near Grange, presents a weird and desolate aspect. There is no soil, the surface being barren limestone, whereupon but a few stunted bushes contrive to grow. Chemical denudation is at work, every joint and small crack in the limestone is widened, and its edges smoothed off by the solvent action of "carbonated water." The limestone is so pure that little argillaceous matter is left, after solution, to support vegetation, so that instead of the usual soil and grass-covered surface we have an arid corrugated waste, more resembling in appearance the "frozen fury" of a cooled lava-flow than the gentle undulating outlines we are accustomed to associate with weathered surfaces of stratified rocks in these islands. A. S. REID.

year. The price of these photographs is so small that they are sure to be much used in museums, colleges and schools for teaching purposes. The subscription list is nominally closed, but we understand that subscribers will still be admitted on the original terms until the end of November.

In congratulating the Committee of the British Association and its secretary on this admirable piece of work, the hope may be expressed that now the way has been shown, foreign societies, if they have not already done so, may follow suit; the subject is one that might well be brought before the notice of the International Geological Congress at its meeting next year in Vienna.

THE CRUISE OF THE "GAUSS" FROM CAPE TOWN TO KERGUELEN.

THE second part of the joint publication of the Berlin Institutes for Oceanography and Geography contains the official report of the work of the German Antarctic expedition on board the *Gauss* on its outward voyage from Cape Town to Kerguelen. The stay in Cape Town was prolonged in order to caulk the ship, which was leaking considerably though not to a dangerous degree, and to make certain changes in the gear and fittings which experience showed to be desirable. Six members of the crew were landed at their own request or as undesirables, and substitutes for them had to be found, and at the last moment two Norwegian volunteers were also taken on board. Prof. Drygalski acknowledges very warmly the hearty reception given him by the authorities at the Cape, which culminated in a military band playing German airs at the pierhead as the *Gauss* took her departure on November 27, 1901.

A course was set for Kerguelen, and the scientific work *en route* was reduced so as not to cause undue delay; still, the opportunity was taken to make thirteen deep-sea

soundings along a track where none existed before. Eleven of these were more than 1000 fathoms, five were more than 2000 fathoms, and the deepest was 2830 fathoms, in 42° 30′ S., 33° 45′ E. The weather was unfavourable with occasional calms, frequent head winds and almost always a very heavy sea rendered the ship extremely uncomfortable. The most interesting episode on the way was a landing which was successfully made on Possession Island of the Crozet group on Christmas Day. Possession Island and East Island came in sight at 5 a.m., the latter thickly veiled in fog, which gradually cleared. The landing was made in one of the numerous small bays of the north-west coast of Possession Island, where the party stepped ashore on a low basalt rock into an idyllic beast-world of slumbering sea-elephants, penguins drawn up in lines of military precision, and sea-birds fluttering curiously close overhead. The coast of the island as a whole was diversified with off-lying rocks and deeply cut caverns, the variety being due to the contrast of the alternate horizontal sheets of hard basalt and soft volcanic agglomerate. Moss grew luxuriantly, and above the cliffs the gentle slopes were in some places covered with marshy vegetation so deeply as to require the greatest care in crossing them. The sea-elephants and penguins furnished a supply of fresh meat which seems to have been appreciated on board; but the Kerguelen cabbage (which seems to have been nearly extirpated by rabbits in Kerguelen itself) was found bitter and unpleasant.

There was no trace of glaciation on the island. A puzzling appearance was presented by the loose material covering the slopes of one of the old craters and stretching down to the sea in stripes alternately wide and narrow in regular sequence, the wide of red, comparatively fine débris, the narrow of coarser fragments of black rock. Neither water nor wind action could account for these remarkable stone streams.

During the three hours on shore, large collections of every kind were made. Fifteen flowering plants were found, three times the number of species formerly known from the Crozets, though all are of species already known from Kerguelen or other islands of the South Indian Ocean. The fauna was found very rich in insects and spiders, several of the species not yet identified being apparently unknown in Kerguelen.

The voyage to Kerguelen continued until January 2, 1902, when the *Gauss* anchored in Observatory Bay, where the land party, who had arrived from Australia some months before, were waiting somewhat uncomfortably. The ship that had brought them had not been able to remain, and her Chinese crew had been such worthless workmen that the labour of installing the land station had been left for the crew of the *Gauss*, who had also to take on board the coal, stores and dogs that had been left for them. Much time was necessarily consumed in this work, everything having to be carried by hand to the boats and rowed out to the ship. About 130 tons of coal had to be left behind, the *Gauss* being full up with 400 tons.

The *Gauss* sailed on January 31 for her destination in the Antarctic with provisions for nearly three years on board. Prof. von Drygalski proposed to visit and if possible land on Heard Island, and then make straight for Wilkes' Termination Island, sailing along the ice towards the west so as to have the prevailing easterly winds of high southern latitudes in his favour, and ultimately turning southward and entering the ice. All on board were full of enthusiasm and confidence, satisfied with the ship, pleased with her equipment and determined to stay in the far south as long as they possibly could. The leader warns his friends not to suppose he is lost if pieces of wreckage from the *Gauss* should be discovered at sea, for she is very likely to lose some of her gear. He thinks it possible he may be able to send news home by June, 1903, but the expedition is planned for two summers in the ice, and no news will be good news until June, 1904.

Dr. Bidlingmaier appends a summary of the meteorological conditions of the whole voyage out from Hamburg to Kerguelen. There are two maps and several illustrations.

MR. CHAMBERLAIN ON EDUCATION.

MR. CHAMBERLAIN visited University College School on Wednesday, November 5, to unveil a memorial tablet to old boys who have fallen in the war, and was afterwards presented with an address from the students of University College. The address, read by the president of the Students' Union Society, referred to the keen support of higher education shown by the Colonial Secretary in his interest in the foundation of the University of Birmingham. We quote the following from the report of Mr. Chamberlain's reply in the *Times*:—

I thank you very cordially for the warmth of your reception. I appreciate the kindness which led you to offer to me this address. I have, as the address states, a very great interest in the higher education of the country. Thirty years ago some of us in Birmingham were prominent in securing for all the children of the country an efficient primary education. We thought it was right that, whatever might be the social position of any child born in this land, he ought to have, as it were, the tools put into his hands in order to carve out a career for himself. That, I believe, was a great and important work. As you know, the Government of which I am a member is now, at this very moment, engaged in the endeavour to develop it. But it left untouched a work which, perhaps, from one point of view, at any rate, is of even greater importance—that is the work of secondary and higher education. It is not everyone who can, by any possibility, go forward into the higher spheres of education; but it is from those who do that we have to look for the men who, in the future, will carry high the flag of this country in commercial, scientific and economic competition with other nations. At the present moment I believe there is nothing more important than to supply the deficiencies which separate us from those with whom we are in the closest competition. In Germany, in America, in our own colony of Canada and in Australia, the higher education of the people has more support from the Government, is carried further than it is here in the old country; and the result is that in every profession, in every industry, you find the places taken by men and by women who have had a University education. And I would like to see the time in this country when no man should have a chance for any occupation of the better kind either in our factories, our workshops or our counting-houses who could not show proof that, in the course of his University career, he had deserved the position that was offered to him. What is it that makes a country? Of course you may say, and you would be quite right, the general qualities of the people, their resolution, their intelligence, their pertinacity, and many other good qualities. Yes; but that is not all, and it is not the main creative feature of a great nation. The greatness of a nation is made by its greatest men. It is those we want to educate. It is to those who are able to go, it may be, from the very lowest steps in the ladder, to men who are able to devote their time to higher education, that we have to look to continue the position which we now occupy as, at all events, one of the greatest nations on the face of the earth. And, feeling as I do on these subjects, you will not be surprised if I say that I cordially agree with what is said in this address. I think the time is coming when Governments will give more attention to this matter, and perhaps find a little more money to forward its interests. When we are spending, as we are, many millions —I think it is 13,000,000*l*.—a year on primary education, it certainly seems as if we might add a little more, even a few tens of thousands, to what we give to University and secondary education.

THE REV. THOMAS WILTSHIRE, M.A., D.Sc.

THE Rev. Thomas Wiltshire, whose death, as already announced, took place on October 26, was for some years professor of geology and mineralogy at King's College, London. To geologists he was, perhaps, best known as the honorary secretary of the Palæontographical Society, a post which he held for thirty-six years, in the course of which time he laboured with unceasing energy in the editing of the annual quarto volumes.

He was educated at Trinity College, Cambridge, and, after taking his degree in 1850, he was ordained deacon by the Bishop of Rochester, and in 1853 priest by the Bishop of London. He resided for many years at the rectory, Bread Street, London, E.C., and took duty in various city churches. While at college his attention became arrested in geological subjects, but his literary contributions were few. Among them were essays on the Red Chalk of Hunstanton and on the history of coal. His work was mainly that of a helper of others. He was one of the earliest members of the Geologists' Association, and served as president from 1859 to 1862. Tothe Geological Society of London he rendered good service on the council, and for many years acted as treasurer. He had also been secretary of the Ray Society.

NOTES.

SCIENCE is represented in the long list of birthday honours by three names. Mr. W. H. Power, F.R.S., principal medical officer to the Local Government Board, has been made a Companion of the Order of the Bath; Sir J. J. Trevor Lawrence has been appointed a Knight Commander of the Royal Victorian Order; and Mr. H. J. Chaney, superintendent of the Standards Department, Board of Trade, has been made a Companion of the Imperial Service Order.

THE following is a list of those who have been recommended by the president and council of the Royal Society for election into the council for the year 1903 at the anniversary meeting on December 1. The names of new members are printed in italics:—President, Sir William Huggins, K.C.B., O.M.; treasurer, Mr. A. B. Kempe; secretaries, Sir Michael Foster, K.C.B., and Dr. Joseph Larmor; foreign secretary, Dr. T. E. Thorpe, C.B.; other members of the council, Mr. W. Bateson, Dr. W. T. Blanford, *Prof. H. L. Callendar*, *Mr. F. Darwin*, *Prof. H. B. Dixon*, Prof. G. Carey Foster, Right Hon. Sir John E. Gorst, *Prof. J. W. Judd, C.B.*, *Right Hon. The Lord Lister, O.M.*, *Prof. G. D. Liveing*, *Prof. A. E. H. Love*, Prof. H. A. Miers, *Prof. E. A. Schäfer*, *Capt. T. H. Tizard, R.N., C.B.*, Prof. H. H. Turner, *Sir J. Wolfe Barry, K.C.B.*

ALL who are familiar with the services rendered to science and humanity by the late Prof. Virchow will be glad to know that a movement has been started with the object of erecting a statue to him at Berlin. It is felt by many admirers of Virchow that the memorial should be more than an exclusively German one, for his labours have benefited the world at large, and in this country in particular he has numerous disciples who would regard it a privilege to give evidence of their esteem for him. The proposed formation of a British Committee to assist the Berlin Committee of the Virchow Memorial will therefore meet with substantial support. Lord Lister has undertaken the chairmanship of the Committee and Sir Felix Semon is the honorary secretary *pro tem.* A meeting will shortly be held to elect officers of the Committee and decide upon a form of appeal for contributions. When the invitation to subscribe to the memorial has been issued, there should be a ready response to it, so that Great Britain shall be worthily represented at the monument of a great benefactor of the human race.

THE Earl of Crawford, F.R.S., who is about to take a winter tour round the world in his famous steam yacht *Valhalla*, has invited Mr. M. J. Nicoll, a member of the British Ornithologists' Union, to accompany him as naturalist. After passing through the Straits of Magellan, the *Valhalla* will visit the principal island-groups of the South Pacific, where its naturalist will have ample opportunities for collecting and observing birds and other animals. The return will be made by the Indian Ocean and Suez Canal.

A MOVEMENT is in progress at the Cape to establish in South Africa a society on the lines of the British Association, to be called the "South African Association for the Advancement of Science." Sir David Gill, K.C.B., F.R.S, H.M. Astronomer at the Cape of Good Hope, is to be the first president of the new association, and Mr. W. L. Sclater, director of the South African Museum, has been asked to preside over the zoological section. The first meeting of the association will probably be held at Cape Town at Easter next year.

THE seventh International Congress of Agriculture will be held at Rome next spring.

A REUTER message from Christiania announces, on the authority of Prof. F. Nansen, that an expedition under the leadership of Captain Amundsen will leave in 1903 for Greenland and King William's Land to locate the magnetic pole. The expedition will afterwards continue its way west and will return home *via* Bering Strait. Captain Amundsen will make systematic magnetic observations in the regions traversed, and will also carry on geographical exploration.

WE learn from the *Times* that M. Trouillot, the French Minister of Commerce, and M. Bérard, Under-Secretary for Posts and Telegraphs, are about to pay visits to all the inventors of systems of wireless telegraphy with a view to the ultimate adoption of one of them.

A REUTER telegram from Rome reports that the Captain of the Italian cruiser *Carlo Alberto* has informed the Italian Ministry of Marine that the vessel was in daily communication by wireless telegraphy with Poldhu, in Cornwall, throughout the voyage from England to Canada, and even when the vessel had entered Port Sydney Harbour. The telegram further states that this achievement confirms the possibility of holding simultaneous communications with Europe and America during the navigation of the Atlantic at least up to a distance of 3000 miles.

ACCORDING to the *Electrician*, some of the wireless telegraph messages transmitted from Poldhu to the *Carlo Alberto* on her recent cruise were recorded on installations not belonging to the Marconi Company or put up on their system. In the last issue but one a letter from the Marconi Company recalls, and repeats, the challenge which Mr. Marconi recently made to Sir W. H. Preece or Sir O. Lodge to show that they could pick up his messages, and questions the ability of the *Electrician* to prove that their messages were genuinely intercepted. In reply, the *Electrician* published last week the tape records with an article by Mr. Nevil Maskelyne describing the circumstances under which they were obtained at the wireless telegraph station erected by the Eastern Telegraph Co. at their cable terminus at Porthcwmow (Cornwall). We call attention to the discussion because it is of special interest in view of the proposed Berlin conference, and of the necessity which we have had occasion to point out on one or two recent occasions for consolidation of the competing systems of wireless telegraphy.

THE annual course of Christmas lectures, specially adapted to young people, at the Royal Institution, will be delivered by Prof. H. S. Hele-Shaw, F.R.S., whose subject is "Locomotion:—on

the Earth; through the Water; in the Air." The first lecture will be given on Saturday, December 27, and the dates of remaining are December 30, 1902, and January 1, 3, 6 and 8, 1903.

At the annual meeting of the London Mathematical Society to be held this evening, Mr. Robert Tucker is retiring from the office of honorary secretary. Mr. Tucker was elected secretary in 1867, very shortly after the foundation of the society, and has held the office continuously until now. During this long period he has grudged neither time nor labour in the interests of the society; it is in large measure owing to his zeal and devotion extended over so many years that the society has advanced from a comparatively local beginning to be the representative society of mathematical science in Great Britain. A circular has just been issued, signed by four past presidents of the society, expressing their belief that many members of the society will concur with them in wishing to offer to Mr. Tucker some permanent mark of their appreciation of his services, and requesting that subscriptions for that object may be sent to Dr. J. Larmor, St. John's College, Cambridge, as soon as possible.

Writing under date November 6, the Paris correspondent of the *Times* states that M. Lacroix, the chief of the French scientific expedition to Martinique, has sent a fresh report to the Colonial Office on the situation in that island. It appears that the zone devastated by the recent eruption is less extensive than was at first thought to be the case. The aspect of the volcano has much changed. A cone has been formed in the crater exceeding in height the former summit. So long as it exists the matter projected will fall in all directions instead of being localised as before on the southern and south-western slopes.

Prof. F. A. Forel sends us from Morges, Switzerland, a cutting from the *Gazette de Lausanne* of October 31 containing a letter in which he describes the sunset effects at Morges on the evenings of October 28 and 29. Half an hour after the disappearance of the sun, following the gradual extinction of the sunset colours, a peculiar secondary brightening of the western sky was observed and lasted for a second half hour. To begin with, the illumination was of a yellowish-green colour, becoming orange later, and sometimes shading into red near the horizon. Now and then a large, purple-lilac coloured circle with a faint halo and ill-defined contours appeared in the west, having for its centre the sun below the horizon. After observing these effects and noting their remarkable similarity to the sunset displays of 1883 following the eruption of Krakatoa, Prof. Forel expresses the conviction that the phenomena noticed by him in October are due to the impalpable dust particles in the higher regions of the atmosphere which are to be traced to the recent volcanic disturbances in the West Indies.

Particulars of the amounts contributed by the various Powers interested in the international scheme of the North Sea fisheries scientific investigation have been given by the Board of Trade. The amount to be expended in this matter by Great Britain during the next three years is 42,000*l.*, inclusive of 1250*l.* towards the maintenance of a central organisation at Copenhagen. The contributions of other countries (exclusive of the latter item) are as follows:—Denmark—initial expenditure, 9600*l.*; annual expenditure, 5500*l.* Germany—initial expenditure, 16,500*l.* (for steamer), 875*l.* (for equipment); annual expenditure, 6250*l.* Holland—initial expenditure, 666*l.* (instruments, &c.); annual expenditure, 2587*l.* Norway—initial expenditure, 9500*l.* (steamer); annual expenditure, 7370*l.* Sweden—initial expenditure, 1055*l.*; annual expenditure, 1066*l.* Russia—initial expenditure, 16,000*l.* (steamer without equipment); annual expenditure, 12,800*l.* Finland—initial expenditure, 6,000*l.*; annual expenditure, 2,228*l.*

The utilisation of the internal heat of the earth has often been suggested as an engineering problem of the future. The Rev. E. Rattenbury Hodges directs our attention to an issue of the *Boston News Bureau* in which a scheme is seriously proposed by the official geologist for Pennsylvania of the U.S. Geological Survey and also by Prof. Hallock, of Columbia University, New York, for drawing on the earth's internal heat by means of deep borings. The idea is to admit cold water into a deep boring and utilise the hot water and high-pressure steam produced. Mr. Hodges points out that he made similar suggestions in the *Popular Science News* for January, 1894, in an article on "Our Heat Resources of the Future." He remarked, however, at the time, "The great objection to this drawing on the earth's ancient store of thermal energy would be that her cooling and consequent shrinking would be accelerated; in other words, earthquakes would necessarily become more frequent, and possibly more violent and destructive in their effects."

The Atlantic forecasts issued at Washington are based on American, Atlantic and European telegraphic reports, and were begun, the chief of the U.S. Weather Bureau states in his last report, at the beginning of 1901. They were, on June 1 of the same year, made a part of the regular general night forecasts published by the Bureau. In a number of instances, when storms of marked strength were passing eastward off the American coast, advices were issued as to the character of the weather which would probably be experienced by steamers leaving European ports westward bound, and by an arrangement with Lloyd's these forecasts have been cabled over here. In addition to the daily forecasts of wind and weather and special storm warnings, predictions of fog have been issued when conditions favourable for fog developments have been indicated in the steamer tracks west of the fiftieth meridian. Reports from Transatlantic steamships have again and again verified these forecasts and special warnings.

The Meteorological Council has issued a valuable supplement to the temperature tables for the British Islands which were published in the early part of this year. Those tables gave the monthly means of the daily maximum and minimum readings for 117 places; the present volume contains the same stations, grouped as before under districts. The table for each month is divided into two parts, showing (1) the values for thirty years and for each five years (for the observations which extend over the whole time), together with the correction which must be applied to reduce the five years' period to the thirty years' period; (2) the five-yearly mean values for those stations for which the observations extend over less than thirty years, but for which an appropriate correction may be obtained from the values in the first part to enable the mean for thirty years to be computed with a fair approximation to accuracy. The work will be found very useful to actual or intending observers who may wish to compare their results with those of longer series at the same or neighbouring localities.

As already stated, the eruption of the St. Vincent Soufrière in the night of October 15–16 was followed by another considerable fall of volcanic ash on the island of Barbados, 100 miles to windward. The particles were found to consist chiefly of minute fragments of felspar, with a little volcanic glass, some ferro-magnesian minerals and a very little magnetite, thus differing considerably from the May samples, which consisted largely of ferro-magnesian minerals, with a considerable amount of magnetite. On this account, the dust of last month is likely to prove of greater fertilising value than that of May last. In connection with the latest dust-storm, the officials of the Department of Agriculture endeavoured to determine the effect produced on insect pests and other pests in the field. Two-

winged flies, "cow-bees," "wild-bees" and other Hymenoptera suffered severely, but other groups escaped practically unharmed, and there is no doubt that the dust has had little, if any, effect on the insect pests. The dust, in fact, destroyed not the pests, but the useful two-winged flies, &c., which prey on the caterpillars and other pests, so that in this way the volcanic ash has tended to disturb the balance of nature. Its effect is declared to be possibly a harmful one except in the case of the present corn crop, as the dust, lodging in the heart of the young plants, prevents the worms eating into the young leaves.

THE third part of the general report and statistics for 1901 relating to the output and value of the minerals raised in the United Kingdom, the amount and value of the metals produced, and the exports and imports of minerals, edited by Prof. C. Le Neve Foster, F.R.S., has been issued as a Bluebook. The first year of the new century has an unfavourable record so far as the mineral industry is concerned. Quantities have been smaller and prices lower. The value of the coal raised during 1901 represented 88·8 per cent. of the total mineral output for the year, but was six million tons less than the previous year, this being the first interruption in the steady rise since the great strike of 1893. Although the output of coal was less than in 1900, more persons were employed in and about the mines. The output of iron ore has continued to fall since 1899, and the diminution of $1\frac{3}{4}$ million tons in 1901 represents $12\frac{1}{2}$ per cent. of the quantity raised in the previous year. The comparative unimportance of the metallic ores, other than iron, is easily understood when it is stated that their value only amounts to 800,000*l.*, which is just half the value of the sandstone and far less than that of the limestone, the slate or the igneous rocks. The oil-shale mines of Scotland yield a product of greater money importance than the tin mines of Cornwall.

WE have received a report on observations of the tidal currents and undercurrents in the Strait of Dover, published by the Hydrographic Department of the Admiralty. The report consists of two parts. The first part contains observations made by Mr. M. F. J. Wilson, engineer-in-charge of the extension works at the Admiralty pier at Dover, with the object of ascertaining whether a report by divers, that the tidal stream changed its direction at the bottom a very long time before the surface, was correct; the result shows that the report was unfounded. The second part contains observations taken by Captain A. M. Field in H.M.S. *Research* in the Dover channel, in order to test the accuracy of conclusions suggested by the observations made by Captain W. V. Moore in 1896, to the effect that on the English side of the Strait the water below a certain depth was still, while the surface current was strong. The earlier observations are shown to have been erroneous, as the tidal streams run to the bottom of the Strait.

Terrestrial Magnetism and Atmospheric Electricity for September contains a biographical sketch of General Sir Edward Sabine, accompanied by a photographic reproduction of the portrait belonging to the Royal Society.

THE Italian Meteorological Office has forwarded us Nos. 4–6 of its *Bolletino mensuale*, or monthly weather review, containing a note on Count Almerico da Schio's attempts at aërial navigation. The form preferred by Count da Schio is a fish-shaped balloon with flexible keel, the Buchat motor yielded 12 horse-power, and the work of construction has been carried on in a private workshop.

A PAPER by Dr. Loria (Genoa), on the origin and development of geometry prior to 1850, has been translated in the *Monist* by Dr. G. B. Halstead. So far as it is possible to sum up briefly the author's conclusions, it would appear that: (1) While it is impossible to determine the first origin of geometrica research, it is certain that the Assyrians and Babylonians studied many important geometrical problems. (2) The geometry of the Egyptians was of far greater importance, and had a particular tendency towards practical applications. (3) Thales and the Ionic period represent the twilight preceding the dawn of Greek geometry. (4) The "golden period" of Greek geometry came within the Alexandrine epoch, its most conspicuous representatives being Euclid, Archimedes and Apollonius. (5) In the list of Greek geometers, Heron of Alexandria and Claudius Ptolemy play a prominent part, and the "silver period" of Greek geometry was notable for the appearance of Eutocius and Proclus, and especially Pappus. (6) The ascendency of the Romans and the subsequent middle ages represent a period of decadence for geometry. (7) The renaissance of mathematics commenced with the appearance of Leonardo Fibonacci (1200 *circa*), and before the end of the sixteenth century we note the names of Tartaglia, Cardan and Ferrari. (8) The primacy of mathematics in France was attained by the appearance of Viète, Mydorge, Pascal and Desargues; Henry Savile of Oxford and Kepler also belong to this period. (9) A new era was introduced by the analytical methods of Fermat and Descartes. (10) In the next section, Prof. Loria traces the influence of infinitesimal methods on the study of geometry, and (11) considers in particular the development of the study of curves and surfaces in three dimensions.

M. G. LIPPMANN, writing in the *Journal de Physique* for October, describes ingenious methods for verifying whether a ruler or sliding bar is rectilinear, and for fixing a collimator in the focal plane of a lens or telescope objective. For the first purpose he attaches one telescope with cross wires to a "chariot" which runs along the ruler, and observes the image of the wires in a second telescope which is fixed. If the two systems of cross wires remain coincident as the chariot runs along the ruler, M. Lippmann concludes that the ruler is rectilinear, and the only exception that could be made to this inference would be if the surface of the ruler formed a series of waves of length equal to the wheel-base of the chariot. To fix the collimating wires in the focal plane of a lens, M. Lippmann now fixes the auxiliary telescope to the chariot in such a way that it can be displaced parallel to its axis, and he uses it to view the wires in the telescope to be tested. If these remain unchanged in position when the auxiliary telescope is shifted, the collimation is correct; if not, the shift of the image determines the amount by which the wires must be adjusted in order to bring them into the focal plane of the lens. The chariot runs on a sliding piece which has been previously tested by the first method.

MR. BASIL THOMPSON, in his "Notes upon the Antiquities of Tonga" (*Journ.* Anth. Inst., xxxii. p. 81), describes the famous trilithon, or *Haamonga*. He inclines to one traditional account which relates that it was erected by Tui-ta-tui in the latter half of the fourteenth century. It was built for him to sit upon during the Kava ceremonies out of reach of his people, as he so dreaded assassination.

SEVERAL years ago, Mr. Henry Balfour published an important memoir on the musical bow, and in the current *Journal* of the Anthropological Institute (vol. xxxii. p. 156) he describes a superficially similar instrument, the *goura*, which Frobenius and Ankermann have confused with the musical bow proper. The *goura* is a bow-like instrument; one end of its string is fastened to a flattened quill, the other end of which is fastened to the bow, and the string is thrown into vibration through the medium of the quill, which is caused to oscillate by being blown upon. Those musical bows which have no resonator are held to the mouth when playing in order to increase the sound, but

with the *goura* the breath causes the vibration, whereas the vibration in the musical bow is caused by tapping or plucking the string.

THE November issue of the *Irish Naturalist* is entirely devoted to the Belfast meeting of the British Association, special attention being directed to papers connected with Ireland.

"PLANKTON" forms the subject of two papers in the *Biologisches Centralblatt*; the September issue contains an account of river-plankton by Mr. A. S. Skorikow, while in the October number Mr. W. Ostwald brings to a close his survey of the theory of plankton in general.

A RECENT issue (vol. iv. part iii.) of *Annotationes Zoologicae Japonensis* contains an account, by Messrs. Ijima and Ikeda, of a rare squid collected at a great depth in the Sagami Sea. The specimen, which is so delicate and translucent that it recalls a jelly-fish, evidently belongs to the genus Amphitretus, founded on a single somewhat damaged example dredged during the cruise of H.M.S. *Challenger*. It is apparently also referable to the type and only species of that genus, hitherto definitely known solely by the original specimen, although a squid taken some time ago in the Agulhas Stream may pertain to the same form. Amphitretus, as its name indicates, differs from all other cephalopods in having the mantle fused in the middle line with the siphon, so that there are two openings of the gills into the gill-cavity on each side.

MESSRS. LAMB AND HANNA have made some interesting experiments upon the neutralising power of anti-venomous serum towards cobra venom and upon the deterioration of this serum through keeping. They find that the maximum amount of venom injected by a cobra into a bite is 45 milligrams, and, assuming that man is as susceptible as the most susceptible animal tested, viz. the rat, estimate that for a man weighing 60 kilograms who received this injection, about 37 c.c. of the fresh serum would be required to save life. They also find that anti-venomous serum undergoes a progressive and fairly rapid deterioration when stored in hot climates, and that this deterioration is greater and more rapid the higher the mean temperature to which it is subjected (*Scientific Memoirs*, Government of India, new series, No. 1, Calcutta, 1902).

ACCORDING to the October number of the *Agricultural Journal* of the Cape of Good Hope, the Government entomologist, Mr. C. P. Lounsbury, has made an important discovery in regard to the propagation of the South African sheep and goat disease known as "heartwater." The so-called bont-tick has nitherto been found to be the only medium of spreading the disease. "A single specimen of this species, if fed on a heartwater-sick animal as a larva or 'seed' tick, has been found capable of transmitting the malady with fatal effect. An animal pastured on veld heavily infested by the tick may drop thousands of pathogenic larvæ during its period of illness and may thus indirectly serve for the almost total extermination of a flock in a few months. The terrible mortality amongst healthy flocks, brought to the coast where the tick is abundant, is thus easily explained. Pathogenic larvæ have been found to retain their dangerous character until they are adult. They may take their second or nymphal feeding on an ox or a non-susceptible goat, and then in the third or final stage get on to a susceptible sheep or goat and give it deadly fever. On the other hand, the disease appears to be non-transmissible through the egg-stage, and the species is normally non-pathogenic in all stages. A farm may be badly infested with bont-tick, yet be entirely free from heartwater." Since the other two common species are innocuous, it is hoped that by keeping down the bont-tick the disease may gradually be stamped out.

A MONOGRAPH of the North American Umbelliferæ, representing the joint work of Prof. J. M. Coulter and Dr. J. N. Rose, has been published in the seventh volume of contributions from the U.S. National Herbarium. The same authors treated this order also for North America in 1888.

THE second quarterly *Bulletin* published by the Botanical Department of Trinidad contains brief articles on the tonka bean, newly-imported mango trees and cane seedlings. Analyses of several Trinidad seedlings yield results which are very promising. An extra number, issued by the same authorities, deals with the cultivation and curing of vanilla in Tahiti. The species grown in that island is mainly *Vanilla pompona*, which yields a less valuable fruit than *Vanilla planifolia*. The former variety has this advantage, that the beans do not split so readily and are, therefore, more easily cured; also it bears flowers twice a year. Pollination is artificially performed, and an efficient worker is said to be able to pollinate two thousand flowers in an eight hours' working day. Curing is a very critical process, as the beans sweat on exposure to the sun, and they must then be covered with blankets and dried at an even temperature.

THE report of the Dominica Botanic Station during the year ending March 31, 1902, contains much valuable information on the work of the establishment, supplied by Mr. J. Jones, the curator; on the experiment plots at the Agricultural School, by Mr. Tannock; and on the cacao experiment plots, by Mr. Whitfield Smith, the travelling superintendent of the Agricultural Department. The monthly rainfall returns from twenty-five stations in the island are also given. Of the various experiments with economic plants, it is interesting to observe that the attempts to introduce early English potatoes are far from being successful at present. Of six varieties planted, three failed completely, two did fairly well and the sixth did excellently. A shipment of 480 pounds of these last was sent to Liverpool, but was not favourably received on the market, experts considering the tubers not bright enough. Still, it is hoped that with further experiments the island may yet compete with the Canary Islands in the production of early potatoes and other vegetables for the English market.

THE Imperial Department of Agriculture for the West Indies continues its series of useful pamphlets on subjects connected with the commercial development of these islands. Mr. A. Howard writes on the treatment of fungoid pests, dealing with them under the head of root, stem, leaf and fruit diseases. The information supplied is for the most part general, but reference is made to the immunity from the so-called "foot rot" or "mal-di-gomma" of sweet orange plants which have been grafted on sour-orange or grape-fruit stocks, and the advantage of treating sugar-cane cuttings with Bordeaux mixture and coating the ends with tar. A second pamphlet gives a number of recipes for cooking West Indian yams, and is issued with the intention of educating the English and American people to appreciate this vegetable.

WE have received copies of two papers read by Mr. H. W. G. Halbaum before the Institution of Mining Engineers, dealing with the difficult problem of mine ventilation and its reduction to simple graphical calculations. One of Mr. Halbaum's objects has been to furnish mining engineers with a form of diagram which shall fulfil the same purpose in the study of mine ventilation that has been so admirably served by Watt's indicator in the case of a steam engine. The second paper deals with an extension of the equivalent orifice theory, in which the writer calculates the relation between the orifice of the ventilating fan and that of the mine in order that the fan may develop its maximum efficiency. It is found that the efficiency is greatest when the orifice of the mine is between one-

quarter and one-half that of the fan, according to the kind of fan used. If the ratio of the orifices is one-third, the efficiency in all these fans is not more than 2 to 3 per cent. below the maximum, but it falls rapidly when the ratio is outside the limits ⅓ and ¼. Hitherto there has been a "good old theory" among colliery workers to have large airways and plenty of them, but this theory Mr. Halbaum compares to remedying the defects of a pump by enlarging its suction pipe. The investigation is largely based on the theories of Mr. Murgue, of St. Etienne, from whom, however, Mr. Halbaum differs in certain particulars. We hope the author will be successful in convincing mine owners that mathematical calculations are of more value than "good old theories," but the slow progress which mathematicians are able to effect in breaking down conservatism in other directions does not make his outlook hopeful.

WE have received the first number of *West India*, a bi-monthly illustrated magazine of thirty pages, published by Messrs. Lightbourn's Sons, price ten cents. Its contents are of a very general character, being "devoted to questions and persons and things generally," in prose and verse. The principal article in the issue before us is one by Mr. Francis Watts, on "Glimpses of the Leeward Islands." The Picture Stone, at Harte's Bay, St. Kitts, is dealt with in verse by Dr. Branch.

UNDER the title of *The Illustrated Scientific News*, a new monthly journal devoted to popular science has made its appearance, and we offer it best wishes for a long and successful career. With the second number, an excellent full-page portrait of Lord Kelvin is presented as a supplement The journal is concerned with inventions and other aspects of engineering work as well as with purely scientific advances. There are, for instance, articles on the 4·7 gun and the Diesel oil engine, as well as on such scientific studies as sounding the atmosphere with kites, Becquerel rays and Foucault's pendulum. Prof. H. H. Turner lightens the pages with a few anecdotes, and asks for other stories of scientific men and manners. This varied contents should find an interested public.

THE thirty-fourth volume of the *Transactions* and *Proceedings* of the New Zealand Institute, which deals with the year 1901, runs to 627 pages and is illustrated by 42 plates. When it is remembered that the Institute includes eight incorporated societies, the proceedings of each of which are here reported, and that the *Transactions* are concerned with zoology, botany, geology, chemistry, physics and miscellaneous subjects, the impossibility of describing the contents of the volume in a short note will be at once understood. In his presidential address to the Auckland Institute, Mr. J. Stewart considered, amongst others, the subject of technical education. He insisted that a youth cannot be taught a trade at a technical school in a manner to enable him to take his place among those who have served a regular apprenticeship to that trade; but that the use of his hands in mechanical handicraft is one of the easiest things for a young man to acquire. The great aim of technical education, he said, is to prepare the intellect to receive and master the scientific basis of all construction and of all manufactures. A paper, also read before the Auckland Institute, by Mr. Elsdon Best, describes very fully the diversions of the "Whare Tapere," a house where the young people of a village gathered at night in order to amuse themselves in various ways, and gives an account of the games, amusements and trials of skill practised by the Maori in former times. A second contribution by Mr. Best of the same date to the same society contains notes upon witchcraft, magic rites and various superstitions as practised or believed by the old-time Maori. Captain F. W. Hutton, F.R.S., is credited with numerous papers, treating of the beetles of the Auckland Isles and other zoological subjects. Other papers are by Profs. Dendy, Benham, A. P. W. Thomas, J. Park and T. H. Easterfield, and when the fifty-four articles brought together in the volume by the director of the Institute, Sir James Hector, K.C.M.G., F.R.S., are considered, the conclusion is reached that science is being worthily advanced by workers at the antipodes.

THE additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mr. T. Turner; a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Mr. E. C. Holland; three Indian Porphyrios (*Porphyrio calvus*) from Java, presented by Mr. A. D. Grange; a Woodcock (*Scolopax rusticula*) European, presented by Mr. W. C. Reid; two Common Chameleons (*Chamoeleon vulgaris*) from North Africa, presented by Mr. E. V. Wash; a Smith's Dwarf Lemur (*Microcebus smithi*) from Madagascar, a Barnard's Parrakeet (*Platycercus barnardi*) from South Australia, deposited; a Stone Curlew (*Œdicnemus scolopax*) European, purchased.

OUR ASTRONOMICAL COLUMN.

COMET 1902 *b* AS OBSERVED IN CEYLON.—Mr. H. O. Barnard, of the Ceylon Survey, has communicated some interesting details of Comet 1902 *b*, as observed by him in Ceylon, to the *Ceylon Observer* of October 11.

He records the comet's appearance, using a telescope of "moderate power," as an egg-shaped mass of nebulosity having a very distinct star-like nucleus which is of a reddish colour, and a tail which extended to about 1°·5 from the nucleus on October 7, giving the whole object a "tadpole" appearance; he further adds that it was easily visible to the naked eye, whilst an opera-glass showed a faint trace of the tail, but no nucleus.

Mr. Barnard's computations show that the comet increased its distance from the earth by 45 million (37 million to 82 million) miles during the period October 8 to 28, inclusive, and that its diameter was 200,000 miles, its volume 600 times that of the earth, whilst the length of the tail, on October 7, was about one million miles.

Mr. Barnard expects the comet to be visible again, in Ceylon, just before sunrise in December.

NEW MINOR PLANETS.—Prof. Max Wolf announces, in Nos. 3821 and 3824 of the *Astronomische Nachrichten*, the discovery of five new minor planets. The dates of discovery, positions and magnitudes of these objects are as follows:—

Planet.		Date.		Heidelberg M.T h. m.	α h. m.	δ ° ′	Mag.
1902	J.V.	Oct.	7	10 38·8	2 9·7	+10 55	12·5
,,	J.W.	,,	7	13 25·8	2 5·2	3 18	13·0
,,	J.X.	,,	7	,, ,,	1 52·9	2 55	13·5
,,	J.Y.	,,	24	12 10·3	1 55·2	12 14	13·5
,,	J.Z.	,,	24	,, ,,	1 59·2	+12 59	13·0

The daily movements of the respective planets are J.V. −0m.·7, −2′; J.W., −0m.·8, −6′; J.X., −0m.·7, −6′; J.Y., −0m.·8, −6′; J.Z., 0m.·7, −8′.

The planet discovered by Prof. Wolf on October 7 and designated 1902 J.U. proved to be the same as (106) Dione.

NEAR APPROACH OF COMET 1902 *b* TO MERCURY.—A telegram from Prof. Pickering, dated Cambridge, Mass., October 29, announces that Prof. Seagrave finds that Comet 1902 *b* will approach to within two million miles of the planet Mercury on November 29.

Herr M. Ebell, Kiel, has confirmed this telegram from the parabolic elements published by Herr Elis Strömgren in No. 3821 of the *Astronomische Nachrichten*, and which were computed from observations made at Lick (September 1), Nicolaiew (September 20·4) and Strasburg (October 8·4). From the ephemeris accompanying these elements it is seen that the declination of the comet will be too southerly for any further observations to be made in England until about the middle of February, and that its brightness at that time (February 11) will be only 2·1 times its brightness at the time of its discovery, whilst by the end of February this ratio will be reduced to 0·6 (*Astronomische Nachrichten*, No. 3821).

THREE STARS WITH LARGE PROPER MOTIONS.—M. A. Verschaffel communicates to No. 3824 of the *Astronomische Nachrichten* the positions of the stars B.D. $+24°\cdot2439$, $24\cdot2733^1$ and $24\cdot2733^2$, as recently observed by him at Abbadia, and compares them with the positions given in the catalogue A.G. Berlin B. and brought to 1900 by the corrections for precession and secular variation given in the catalogue, thereby demonstrating the existence of a large amount of proper motion for each star.

THE PYRAMID SPOT ON JUPITER.—Herr Leo Brenner, in writing to *The Observatory* (No. 324), explains the great discrepancies which have appeared between the positions, and velocity, of the "pyramid" spot as determined by himself and as determined by the English observers Messrs. Denning and Phillips.

He found that the centre of the formation travelled, during a year, at the mean velocity of $0°\cdot5$ per day, and then Messrs. Denning and Phillips recorded that, according to observations made on June 28, it had moved at a mean velocity of nearly $7°\cdot0$ per day for a period of nine days. This great change of velocity seemed impossible, but Herr Brenner has found a solution to the difficulty in the observed fact that it is not *one* spot that is being observed, but a series of three or four spots, and of these, some are new formations of which Messrs. Denning and Phillips had measured the position as though they were portions of the original spot, thus obtaining the great differences in position noted above.

Herr Brenner has arrived at the conclusion that neither the markings seen by him during August and September, nor those seen by the English observers on June 28, can be identical with the "pyramid" spot of last year, and these conclusions are strengthened by the observations of Señor Comas Solá, which were published lately in the *Bulletin de la Société Astronomique de France*.

EPHEMERIS FOR COMET TEMPEL$_3$-SWIFT.—In continuation of the ephemeris given in *Astronomische Nachrichten*, No. 3811, M. J. Bossert now publishes the following ephemeris for this comet.

12h. M.T. Paris.

Kiel Circular, No. 53.

THE AUTOMATIC TELEPHONE EXCHANGE.

THE object of the automatic telephone exchange is to dispense with the assistance of a third party in making connection between two subscribers. Those who are at all familiar with the complexity of the connections and of the numerous devices needed in a modern exchange having a large number of subscribers will realise that to work out a system in which the telephone girl is replaced by an automatic arrangement is a matter requiring no little ingenuity, and will, perhaps, not be surprised that the problem has apparently only been attacked successfully on the other side of the Atlantic. The American technical papers have shown that, during the past few years, the construction of automatic exchanges has received considerable attention and that several different systems have been worked out. Some attempts have been made to introduce these into this country, but not with much success; in fact, until the last year or so England did not afford a promising field for the introduction of automatic telephones unless for small private exchanges. In America, however, matters are different, and, as we have said, descriptions of two or three different systems in actual or experimental use have been published. One of these, recently described in the *Scientific American*, is noteworthy for the fact that the automatic apparatus at the exchange is operated mechanically so far as possible, the electrical control being reduced to a minimum. Greater trustworthiness, it is said, is obtained by this means, though we should be inclined to think that the wear and tear would also be greater. We do not know whether this, the Faller, system has had any extensive trial as yet. Another system, which we propose to describe briefly, has been in operation in some parts of America for three or four years, and as it is being installed now in several large American towns, and is also being introduced into Germany and England, we may judge that it has proved both trustworthy and economical. In Chicago, an exchange on this system is being constructed with an ultimate capacity of 100,000 subscribers.

This system is known as the "Strowger" system. We have had an opportunity of inspecting a small model installation representing part of an exchange suitable for 10,000 subscribers, and were struck by the ease and simplicity of its working and its great convenience from the subscriber's point of view. Of course, working a small portion of an exchange under exhibition conditions is one thing and running the complete system continuously, with all the subscribers connected, is another; but there was little to lead one to suppose that the working under the more arduous conditions of actual service would be any less satisfactory, and indeed the success which has attended the operation of three or four large exchanges in America is direct evidence to the contrary. One of these, at Fall River, Mass., has been in operation for two years and, with an ultimate capacity of 10,000 subscribers, already has 4000 connected. Apart from the clerical staff, only five people are required to look after this exchange, and these are said to spend most of their time connecting up new subscribers; at night and on Sundays the exchange is left to take care of itself.

We may first of all consider the subscriber's instrument; this takes no more room than, and looks very much like, an ordinary wall set. There is, however, no magneto ringer, and on the front of the box is a circular metal disc having ten holes on the right-hand side numbered from 0 to 9; below this is a ringing-up push. Suppose a subscriber wishes to call up No. 5683; he takes his receiver off the hook in the usual manner and, putting his finger in the hole marked 5, rotates the disc until his finger comes against a stop; he then allows the disc to return to its normal position and repeats the operation with the holes marked 6, 8 and 3 in succession. He is now connected through, and if No. 5683 is engaged, will hear a buzzing in his receiver; if not, he has only to press the ringing-up push and wait until his call is answered. When he puts back his receiver on the hook, all the connections are restored to their original condition. The time taken to get connected through—or to find out that the number you require is engaged—is considerably less than with the ordinary system, even when the exchange girl replies to your call and connects you up immediately, which, as telephone users know, happens but rarely.

The apparatus at the exchange consists of a number of automatic switches known as "first" and "second selectors" and "connecting switches." The construction of all these is very similar, but is too complicated to describe in detail; we can only indicate the principle upon which they work. The switch consists of a semi-cylinder, along the axis of which is the switch-arm. This arm can be raised or lowered in ten steps and also rotated so that its contact can be brought up to any of the contacts on the inside of the semi-cylinder; these are arranged in ten rows of ten contacts each. We may best understand the operation of these switches by following out what happens on ringing up, say, No. 5683. Each subscriber has a "first selector" switch of his own at the exchange, and the first movement of the dial on his instrument operates this switch. As he draws down the hole 5 to the stop, a succession of five current impulses are sent along the line, and these raise the central switch-arm to the fifth row up on his switch. This picks out all the subscribers whose numbers begin with 5000, by connecting the caller to the group of "second selectors" corresponding thereto; there are ten connecting or "trunk" lines leading from the first selectors to the second, and the switch-arm, when it has risen to the fifth row, rotates until it picks out a disengaged trunk, passing over any which are in use by other subscribers. The second movement of the dial operates the second selector in precisely the same way, raising its arm to the sixth row of contacts and causing it to rotate over that row until it picks out a disengaged trunk line leading to the group of subscribers with numbers beginning with 5600. The remaining two movements operate the selector switch and are

slightly different; the first raises the arm to the eighth row of contacts and the second rotates it to the third contact in that row. The subscriber is now connected to No. 5683 and can ring him up if he is not engaged; the signal that he is engaged is given through another set of contacts on the connector switch, an interrupted current being sent along the caller's line and causing his receiver to hum. When the conversation is finished and the caller hangs up his receiver, all the switches which he has been using return to their normal position of rest.

The exchange is run on the central-battery system and metallic circuits are used throughout. It will be noticed that the subscriber's connections are duplicated at the exchange, one pair of wires running to the first selector and one to the contacts corresponding to his number on the connectors. It is also obvious that the number of connections in one group of hundreds or thousands which can be made at once is limited by the number of trunk lines; ten of these per hundred subscribers have been found to be practically sufficient, but the number could, of course, be increased without limit if it was found desirable. Once two subscribers are connected through, their conversation cannot be interrupted, since any attempt to call either up results merely in the caller receiving the busy signal, and any calling up between other subscribers does not affect the lines they are using. This alone is a very great convenience from the user's point of view; in addition, the gain in time in getting connected up, the impossibility of getting on to a wrong number except by the subscriber's own fault and the secrecy of the system must be reckoned to its advantage. So far as the exchange is concerned, the chief advantage lies in doing away with the exchange girl; the cost of maintenance is said to be no more than in a manually operated system, the floor space required for connections and switches about the same; there is, therefore, a slight saving in room, since none of the resting rooms which the strain upon the operators now renders necessary is required.

M. S.

INSTANTANEOUS CHEMICAL REACTIONS AND THE THEORY OF ELECTROLYTIC DISSOCIATION.[1]

IT is generally held that instantaneous chemical reaction, if not all chemical action, is dependent upon ions; in other words, that such reactions take place between electrolytes. In order to test this point, the author has attempted precipitation by double decomposition (like the reaction between silver nitrate and hydrochloric acid) in solutions that are excellent insulators. As a solvent benzene was chosen, though it seems that petroleum ether or toluene would have been equally good. The benzene used was the best that is made by Kahlbaum, free from thiophen. It was allowed to stand for days over phosphorus pentoxide, from which it was distilled, and was finally kept standing over metallic sodium. The conductivity was tested by comparison with that of air. For this purpose an Arrhenius resistance cell, with plates less than a millimetre apart, was placed in series with a sensitive galvanometer, and a dynamo giving a pressure of 110 volts. When the cell contained air a slight movement of the needle could be seen on closing the circuit, and on replacing the air by benzene the deflection was somewhat less. The insulating properties were therefore good.

Some difficulty was found in obtaining suitable solutes owing to the general insolubility of salts in hydrocarbons. Certain oleates, however, are soluble, and those of copper, nickel and cobalt were used. These were prepared by heating pure oleic acid with the calculated quantity of standard solution of sodium hydroxide and then adding to this sodium oleate solution a slight excess of the sulphate of the heavy metal. The precipitate was thoroughly washed with water and finally dried at 110°. The salts so obtained were analysed by reduction in hydrogen.

These oleates are readily soluable in benzene, even in the cold, and give colours similar to those of salts of the corresponding metals in aqueous solutions. On heating the dark red solution of cobalt oleate in toluene it turns blue, and on cooling it again becomes red, in the same way as cobaltous salts change colour in aqueous solutions. It was found that 5 per cent. solutions did not conduct any better than pure benzene. Metallic sodium does not cause any precipitation, and was, in fact, used as a desiccating reagent; the only change that ever took place was the usual slight pinkish coloration that freshly cut surfaces always assume after a time. Magnesium, aluminium and zinc have been kept in a copper oleate solution for weeks without in the least changing their appearance and lustre. It is therefore abundantly proved that these oleates in benzene are not ionised. Cryoscopic determination of the molecular weight of copper oleate in benzene gave figures about 2400 and the boiling-point method about 2650, whereas the theoretical figure is 625·6, so that, according to the usual idea, the copper oleate would appear to be polymerised.

A solution of dry hydrochloric acid gas in benzene was next prepared. The gas was obtained by dropping the aqueous solution into concentrated sulphuric acid and further drying by sulphuric acid and phosphoric anhydride. The conductivity of this solution was no higher than that of the benzene itself. It does not attack the carbonates of sodium, calcium and barium, or bright magnesium ribbon. Zinc, however, is attacked, whether amalgamated or not, but platinum in contact with it makes no difference, the hydrogen being evolved from the zinc alone. Thus voltaic action is absent. A dilute aqueous solution of the acid seemed to act rather less readily on amalgamated zinc than did the solution in benzene. Similarly, contact with platinum or other metals does not cause magnesium to be acted on by the acid. Iron, nickel, cobalt, copper and cadmium are not attacked; tin and aluminium are slightly acted upon, and lead very slightly. This is so whether the metals are by themselves or in contact with others. Metallic sodium is fairly rapidly attacked. The chlorides of the metals acted upon are practically insoluble in benzene.

In all the experiments, great precautions were taken against moisture, the generators and other apparatus being connected to suitable drying trains. The flask containing the benzene and substance to be tested was fitted with a doubly perforated rubber stopper, and was connected with the drying train of the hydrochloric acid generator and also to a large tower filled with pumice and phosphoric anhydride. Before introducing the benzene and substance, the flask, stopper and connecting tubes were heated to drive off moisture, and while still hot, the benzene and substance to be tested were quickly introduced and the whole at once connected with the train. The air was then displaced with dry hydrogen, which passed through the hydrochloric acid generator, and finally the acid was slowly evolved until the train was saturated.

When dry hydrochloric acid gas is passed into a solution of copper oleate in benzene, there is formed instantly a heavy brown precipitate which is cupric chloride. We have here, then, a case of instantaneous precipitation by double decomposition which is perfectly comparable with that of the formation of silver chloride in aqueous solutions, when silver nitrate solution is treated with hydrochloric acid. Yet the benzene solutions conduct no better than benzene itself, nor is there the least perceptible increase of conductivity at the instant of the formation of the precipitate. The oleates of nickel and cobalt, when treated in benzene solutions with dry hydrochloric acid, react in a perfectly analogous manner. Analysis showed the precipitation to be complete.

It was found that the conductivity of two samples of anhydrous stannic chloride is no better than that of air. This salt mixes with benzene in all proportions, giving mixtures which are equally non-conductors. Yet when such a solution is poured into a benzene solution of copper oleate, there forms *instantly* a heavy brown precipitate which is principally anhydrous cupric chloride. The precipitate takes down some of the stannic oleate which is formed with it and is difficult to manipulate, but analysis shows that the reaction is in the main a simple double decomposition.

Anhydrous phosphorus trichloride, arsenic trichloride and silicon tetrachloride are miscible in all proportions with benzene and give solutions which are insulators, like the solution of stannic chloride. In each case, when a solution of copper oleate in benzene is treated with a solution of PCl_3, $AsCl_3$ or $SiCl_4$ in the same solvent, copper is precipitated as a dark brown precipitate. This is essentially cupric chloride, but is in each case contaminated with some of the oleate.

We see, then, that HCl, $SnCl_4$, PCl_3, $AsCl_3$ and $SiCl_4$ each precipitate cupric chloride from benzene solutions of copper oleate. There is, then, apparently double decomposition by means of ions, and yet the solutions are non-conductors, showing that ions are not present.

[1] Abstract of a paper in the *Journal of Physical Chemistry*, vol. vi. pp. 1-14, 1902, by L. Kahlenberg.

As in the case of aqueous solutions, the solubility of the precipitate is diminished by adding excess of the precipitant. When dry hydrogen sulphide is passed into benzene solutions of the oleate of copper, nickel or cobalt, the sulphides of the metals are at once thrown down. If these solutions are first saturated with hydrochloric acid so as to precipitate the chlorides and then saturated with dry hydrogen sulphide, the sulphides do not form. Stannic chloride dissolved in benzene was treated with dry hydrogen sulphide in large excess without any visible formation of sulphide; but on standing overnight there was a copious precipitate. Arsenic trichloride in benzene showed a similar reluctance to form sulphide, but when petroleum ether was used as a solvent the formation was almost instantaneous.

Hughes has found that dry hydrochloric acid will not react with dry ammonia, a fact which the author has confirmed. Yet when anhydrous benzene is treated with hydrochloric acid dried over sulphuric acid and phosphorus pentoxide, and then ammonia (evolved by heating lime mixed with ammonium chloride and dried by passing through a tower of lime and one of dry pumice covered with phosphorus pentoxide) is passed into the solution, a white, bulky precipitate of ammonium chloride at once forms; the benzene vapours are enough to cause the reaction to take place. Neither of the solutions, nor the mixture, conduct better than benzene itself, nor is there any change of conductivity at the instant of mixing. Similarly, when anhydrous pyridine is mixed with benzene, the solution is a non-conductor. But when such a solution is mixed with a solution of hydrochloric acid in benzene there is at once formed a heavy precipitate of the hydrochloride.

We must therefore conclude that instantaneous chemical reactions are possible with non-conducting solutions as well as with electrolytes. W. R. C.

A MEDIÆVAL TREATISE ON SURVEYING.

PROF. HAMMER, of Stuttgart, who has from time to time published interesting contributions to the history of geodesy and of surveying instruments, has given in a recent number of the *Zeitschrift für Vermessungswesen* a detailed account of Reinhold's treatise on surveying and mine surveying, a little-known work that enjoyed great popularity in Germany in the Middle Ages. In the bibliography appended to Brough's "Mine Surveying" (ninth edition, 1902, p. 360), Reinhold's book appears as the earliest independent treatise on the subject. In view of the far-reaching influence exercised by the work, a brief analysis of the contents may not be without interest.

The title of the book is "Gründlicher und warer Bericht vom Feldmessen" It was published at Saalfeld in 1574 by his son, Erasmus Reinhold. Reinhold senior was born at Saalfeld in 1511 and died there of the plague in 1553. From 1536 until his death he was professor at Wittenberg. The main contents of the book would appear, therefore, to have been written in the middle of the sixteenth century. The preface, written by Erasmus Reinhold junior, a physician, gives examples of errors made in surveying. Thus, a large forest was measured thrice; the first determination gave an area of 26,000 acres, the second 36,000 acres, and the last 27,000 acres. The author divides his "Bericht" on surveying into five sections. The first deals with the four rules of arithmetic, the extraction of square roots, &c.; the second deals with the calculation of areas; the third with the dividing up of land; the fourth shows how the rules given may be applied in districts where other measures of area are in use; and, lastly, the fifth section enumerates the rules of surveying so as to enable, as the author puts it, a common man of sufficient intelligence to carry out his own measurements without further great ado. The second part of the work is devoted to an account of the quadrants and of the compass, and to a treatise in nineteen chapters on mine surveying.

In the first part of his book Reinhold complains that it is rare to find a town which uses the same names and sizes for field surveying as its neighbours. Morgen, Juchart, Tagwerk, Mannsmahd, Hufe, Hufacker, Artacker, &c., are among the units of area met with. He therefore carefully enumerates his measures of length and area, with the symbols used for them throughout the book. The unit of length is the rod (*Ruthe*) of 16 feet (*Werkschuh*), each of which is again divided into 16 finger-breadths (*Fingerbreit*). The unit of area is the acre (*Acker*) of 150 square rods (*gevierdt Ruthen*). The Werkschuh, on which his whole system of measures is based, is dealt with by Reinhold in a peculiar manner, very characteristic of the period. He says in effect: how long, however, a Werkschuh is, is known to everyone, or can easily be ascertained from any carpenter, mason or cabinet-maker. Later on in the volume he gives a woodcut showing the length of a third of this foot, from which it is evident that the Werkschuh was 281 millimetres long, and consequently the Ruthe was 4·50 metres long, which is in close accord with the old Brunswick rod of 16 feet (4·566 metres). A square rod would represent 20¼ square metres, and the unit of area, the Acker, would contain about 3040 square metres, which is in fair accord with several of the Morgen in use in Germany before the introduction of the metric system. For the measurement of lengths, Reinhold advocates the use of a cord or rods. A wire cord is preferred to a hemp one, as not being affected by weather or by varying tension. For setting out a right angle the author makes use of the right-angled triangle with the sides 3, 4 and 5. He also recommends the numbers 20, 21 and 29, as well as the approximation with the numbers 12, 12 and 17 ($12^2 + 12^2 = 288$, whereas $17^2 = 289$). In reference to the latter method, he reminds the reader that he writes for the common man who does not require everything to be weighed on a gold-balance. Areas are calculated by means of rectangles, trapezoids and triangles, attention being given to the measurement of lakes and woods and other polygonal figures in which diagonals cannot be measured. For the measurement of angles the compass is used. It is graduated into single degrees, each 5 degrees being numbered consecutively from 0 to 360°. The direction of the pointer in the illustration given represents a westerly declination of about 6°. Lastly, the trigonometrical solution of triangles by the aid of a table of natural sines is explained. The next section of the work deals exhaustively with the division of land. Errors, it is pointed out, frequently occur which a good surveyor could easily prevent. Every prince and town, therefore, should, as the author quaintly puts it, have a licensed, but nevertheless competent, surveyor. The second division of the whole work is devoted to mine surveying. The instruments described include the compass, a good quadrant, a water-level and a hanging clinometer. The unit of length in mine measurements was the *Lachter* (fathom) of 6 shoes, and the technical terms then used were much the same as those now in vogue in German mines.

Such in brief are the contents of this remarkable treatise written 350 years ago. Comparing it with some of the most recently published text-books on surveying, it is depressing to find how little is the progress that has been made in the instruction in this important branch of engineering. In a large treatise on the subject published this year the statement is made that a slight knowledge of geometry is necessary, and consequently a chapter is inserted in the middle of the book dealing with geometry, trigonometry and logarithms. The development of the theory of measurements and the mathematical principles on which it is based are neglected, and the author confines himself to enunciating mechanical rules for the testing of surveying instruments and for carrying out surveys. This rule-of-thumb method of education was not enough for Reinhold in 1550, whilst in 1782 Prof. Lempe, in his lectures at the Freiberg School of Mines and in his text-book, went still further by urging the necessity of learning and applying arithmetic, geometry, plane and spherical trigonometry, and even analytical geometry and the elements of the differential and integral calculus, as the surest basis of a successful study of mine surveying. B. H. B.

DYNAMIC INTERPRETATION OF CELL-DIVISION.[1]

THE author came to the study of biology possessing, as a civil engineer, an equipment rare among the disciples of this science. Some years ago he interpreted the phenomena of cell-division and karyokinesis as due to the play of Newtonian forces of equal potential but opposite sign, rather than to the gross actions of pull or push performed by ordinary mechanical forces; and was able to reproduce the spindle-figure and centrosomes by a trough full of spirits of turpentine in which were suspended crystals of sulphate of quinine, and into which were introduced a pair of wires joined to the poles of an electric machine. After continued study under such masters as Giard, he now develops

[1] "Interpretacion Dinamica de la division Cellular." By A. Gallardo. Pp. 101. (Buenos Aires, 1902.)

the same conception and extends it in a thesis for the doctorate. The cytoplasm of a dividing cell is differentiated as the site of a field of force; the spindle with its asters is the visible embodiment of the lines of force; the centrosomes occupy the poles, that is the points of maximum potential and of physical equilibrium, though it is not legitimate to say that they are themselves either the sources or the causes of the molecular stresses and strains. Where the centrosome expands into a large zoned astrosphere, as in the eggs of Rhynchelmis or Unio, the zones correspond to equipotential surfaces. It has been objected to such views that they will not explain multipolar figures, such as often occur in nature: but a tripolar figure can be formed in the above *electric* working model by introducing a third terminal put

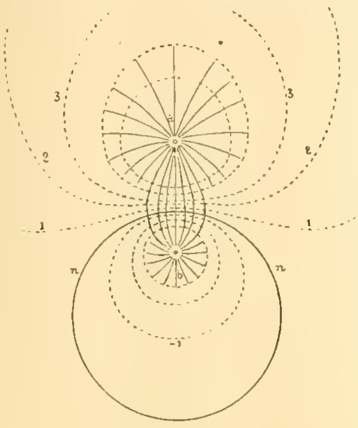

FIG. 1.

to earth; while a quadripolar spindle can be reproduced by a *magnetic* model where iron-filings group themselves under the action of four poles alternately arranged at the consecutive angles of a square. But perhaps the most convincing illustration is supplied by two consecutive figures; the one (Fig. 1) is a geometrical construction to represent the plane section of a field of force passing through the poles, and displaying the system of equipotential zones and lines of force, when the charges at the poles are + 5 and − 3 respectively; and the other (Fig. 2) is the de-

FIG. 2.

lineation of an unequal mitosis in the connective tissue of a salamander-larva copied from F. Reinke.

The splitting of the chromosomes and the repartition of their twin moieties are referred to the same forces, which he terms "karyokinetic" not to prejudge their real nature. He suggests that in direct or amitotic divisions of the cell and nucleus the same forces are at work, although no material presentment of the lines of force is seen.

The whole of this part is admirably worked out: it is quite free from those mathematical short-cuts, which are, indeed, indispensable for the rapid daily work of the physicist, but which Faraday, the great investigator of polar forces, was able to dispense with, and which are for the most part incomprehensible if not revolting to the biologist.

Gallardo regards heredity as the transmission from cell to cell of the power to develop such forces in due course. That these forces are neither electric nor magnetic is certain. It is unlikely that Bütschli's suggestion that they are osmotic is adequate, though doubtless osmosis does play a part in the process. Gallardo is content for the moment to regard them as "vital" forces, avowing that he is so far a vitalist as to admit that the phenomena of living beings present problems and characters not found in inorganic or dead groupings of matter. He does not, however, accept J. Reinke's "dominant" hypothesis.

We ourselves greet this pamphlet the more cordially as embodying ideas that we have held for years—nay, have attempted to work out. The task, however, could only be accomplished by one who possessed a solid grasp of modern physical science as well as of biological fact. We may note that the device we have adopted for modelling in three dimensions the karyokinetic figures—a glass trough of glycerine in which are suspended the finest iron-filings, levigated in alcohol—will be found useful by the physicist; for by moving it from place to place in a magnetic field he can render the courses of the lines of force visible, and map them out in space for himself or his students.

MARCUS HARTOG.

THE RABBIT PEST IN AUSTRALIA.[1]

IT was hoped and expected that the long-continued drought which has prevailed throughout eastern Australia for the last six years would at least have had a good influence in subduing the rabbit pest, but such does not seem to have been the case. The rabbits, like all other living animals, have suffered severely in certain districts, but on the least mitigation of the drought they quickly recover themselves, and become as numerous and as destructive as ever. Large tracts of country formerly able to maintain sheep have been abandoned, we are told, on account of the rabbit pest, and have gone to waste in consequence of the futility of the various schemes that have been tried for the mitigation of this frightful evil.

In these circumstances, Mr. William Rodier, of Tambua Station, Cobar, New South Wales, has done well to reprint the pamphlet on this subject to which we directed attention on a former occasion (NATURE, March 21, 1889), and to explain more fully the very simple and efficacious method by which he proposes to deal with the rabbit pest. Had the scheme put forward by Mr. Rodier been adopted when it was first suggested, we do not doubt that the success which it has met with on his own station would have followed it elsewhere. But, as we all know too well, the prophet has little honour in his own country, and, instead of following Mr. Rodier's excellent advice, the authorities have tried various other schemes that have in many cases only had the effect of augmenting the evil.

Mr. Rodier's plan for combating the rabbit pest is very simple. It is based on the well-known law of nature that polygamy is favourable to the increase of offspring and polyandry is unfavourable. Rabbits usually live in a polygamous state. One male impregnates a number of females and produces a large offspring. Mr. Rodier proposes to convert this polygamy into polyandry by catching the rabbits alive and killing all the females, while all the males are turned out again. If this is done, the male rabbits become more numerous than the females, harass the females by their constant attentions and injure their powers of breeding. Thus the offspring becomes continually less numerous. That this result will follow is illustrated by the case of public women, who seldom bear children and never produce large families, and by other facts well known to science.

The ordinary course pursued in trapping rabbits, in which all that are caught are killed, so far from diminishing the evil is much more likely to increase it. The great majority of the rabbits captured are sure to be males, because the male rabbits have the habit of congregating in certain spots called "buck-heaps." In these spots they are easily caught by the trappers, who are, of course, only anxious to kill as many as possible and to obtain the fees offered for their destruction by the Rabbit Acts. Thus the males become diminished in numbers and the breed becomes increased. Various other modes of combating the rabbit pest have been tried in Australia, but all alike have proved to be failures. Poisons of different descriptions have been much

[1] "The Rabbit Pest in Australia, its Cause and its Cure." By W. Rodier, Pp. 16. (Sydney, 1902.)

used. This is done by spreading poisoned grain about the runs of the rabbits or by poisoning the water-tanks. But poison has not turned out successful, and there is besides great objection to the employment of such a dangerous agent in any case.

The introduction of some infectious disease to kill the rabbits has also been advocated, and even tried in certain districts, but it has not succeeded. In this instance, even Pasteur attained no definite result.

In these circumstances, Mr. Rodier's plan, as set forth in his pamphlet, which is certainly theoretically correct, ought to be tried by the authorities on a large scale. It would be easy to fence round a few thousand acres in one of the worst districts and see what effect will be produced by capturing the rabbits alive and killing only the females. Mr. Rodier tells us that his plan has succeeded well at Tambua Station, and there is every reason to suppose that it would succeed elsewhere if it were properly tried.

THE ROYAL HORTICULTURAL SOCIETY.[1]

FEW things have been more gratifying to those "seriously" interested in horticulture than the great improvement that has taken place in the publications of the Royal Horticultural Society during the last few years. The Society has more than recovered from the disasters that befell it at South Kensington. The present year is not yet completed, but already more than one thousand new fellows have been elected. There is every probability that the approaching centenary will be fittingly celebrated by the erection of proper offices, including an exhibition hall and accommodation for the excellent Lindley Library. This latter is the property of certain trustees, but is inseparable from the Society so long as it exists as a corporate body in or near the metropolis.

One potent reason for the phenomenal success which has of late years distinguished the Society is to be found in the zeal, energy and organising faculty of the secretary. In no respect are these qualities more conspicuously illustrated than by the publications of the Society edited by him.

The papers contributed to the *Journal* have almost always been good of their kind, but they were published at irregular, often very long, intervals, so that interest in them flagged or disappeared entirely.

Under the editorship of the present secretary, the quality of the *Journal* has been more than maintained, whilst comparative regularity of publication has been ensured; so that those fellows whose distant residence precludes them from availing themselves to the full of their privileges may yet be assured that in the *Journal*, as now issued, they have a full equivalent for their subscription, and, as far as possible, are kept abreast of the proceedings at headquarters.

The current number shows an improvement on its predecessors in the fact that a larger infusion of original illustrations has been vouchsafed. Among these we may mention the three coloured plates illustrative of several of the more common fungi which attack garden plants. The article on which these plates confer additional value is the production of Dr. M. C. Cooke, and we are glad to see it is marked "to be continued," for a more complete list of this kind than any that has yet appeared is greatly wanted by gardeners. Another paper illustrated by original half-tone blocks is that on "plant communities" by Prof. Carr, of Nottingham; at least we are not so familiar with them as with the numerous cuts which have done duty before in the various horticultural journals.

During the last year or two, a very useful addition has been made to the Society's records in the shape of short abstracts from current horticultural literature relating to the garden and its inhabitants. These are supplied by a goodly number of trained experts, and when experience has taught them a due sense of proportion and a more rigid selection of what is appropriate to a horticultural journal, their value will be even greater than it is now. This portion of the volume will require the greatest care in indexing, as without a comprehensive index reference will be greatly hampered. The contents are so varied that further detailed comment is impracticable. It must suffice to say that all classes of horticulturists, practical, scientific, æsthetic or amateur, will find something to interest them in these pages.

[1] *The Journal of the Royal Horticultural Society* (September, 1902). Edited by the Rev. W. Wilks, M.A., Secretary.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The resolution, "That candidates shall not be required to offer both Greek and Latin in the examination in stated subjects in Responsions," submitted to Congregation on Tuesday, was lost by 189 votes to 166. If the resolution had been carried, a proposal would have been brought forward on November 18, "That all candidates shall be expected to pass in two out of the four following languages:—Greek, Latin, French and German, one of the two being either Greek or Latin." By the decision of Congregation on Tuesday, Greek remains a compulsory subject at Responsions for all candidates; but the subject may be brought up again by a proposal to exempt candidates for honours in certain of the final schools from the compulsion of Greek.

Mr. George Herbert Grosvenor, B.A., New College, has been appointed to the biological scholarship at Naples for the year 1902–3.

THE late Colonel Walter Montgomerie Neilson, who was the son of the inventor of the hot-blast as applied to iron-smelting, and who, in a sense, was the founder of the locomotive trade in the Glasgow district, has made a bequest of 500*l.* in memory of his father, Mr. James Beaumont Neilson, to the Glasgow and West of Scotland Technical College, for the establishment of a gold medal and prize to be awarded each year to the best student of the College completing his course of study of three years for the diploma in mechanical engineering. The medal and prize are to continue the name of, and the invention by, Beaumont Neilson. The medal will be of the value of 10*l.*, and the prize will consist of books.

DR. G. R. PARKIN, the organising agent for the trustees of the Rhodes scholarships, is at present in Oxford to consult with the University and college authorities before proceeding to frame, for the approval of the trustees, a scheme for the election of the scholars. Dr. Parkin states that according to their size, each of the colleges seems prepared to take from two to five of the Rhodes scholars every year. This would give to the smaller colleges six in all for the three years' scholarship, and to the larger colleges about fifteen, when the plan is in full operation. The first year the bequest comes into operation there will be elected probably between seventy and seventy-five scholars, the same number for the second year, for the third year about thirty, and in subsequent years the same proportion will be maintained.

IN the course of an address delivered at the Liverpool School of Science on Saturday last, the Bishop of Liverpool remarked that the time had passed for ever when Great Britain stood first and the other nations of the world nowhere. There was great need for energy and exertion, and great care must be taken to develop on educational lines as fast as possible. Technical schools were meeting a real national need and helping to preserve the greatness of the Empire. They were bringing British science and industry together, and in future they would find that science would transfigure industry, and industry would make science more practical. But what were first needed were the unification of education and the full sympathy and cooperation of employer and employed, in which respect foreigners were somewhat ahead of us.

M. BORIS WEINBERG, of the University of Odessa, has recently completed an interesting inquiry into the provisions for the practical study of science made in 206 laboratories in connection with colleges in Europe, America and Australia. In March, 1900, M. Weinberg sent a circular letter to the directors of all physical, mechanical, electrotechnical and chemico-physical laboratories mentioned in the "Minerva Jahrbuch," asking for information as to the number of demonstrators teaching in the laboratories in 1900 and in previous years so far back as 1865, the number of students in the same years, the smallest number of students working at the same time in the laboratory, the hours devoted to practical work by each student during a week, and many similar points. His results are now published, and deal with typical university colleges, medical schools, technical colleges, &c., of the countries of Europe, of the United States and of Australia. The most valuable part of the information brought together in the pamphlet is the careful

analysis of the courses of study in physics in the different institutions from which data were received. In his circular to laboratory directors, M. Weinberg tabulated some 910 typical practical exercises in physics and requested that those worked in the laboratories might be underlined. It has thus been possible to institute an instructive comparison between the methods of different countries. About four hundred physical laboratories, having five hundred professors and eight hundred demonstrators or assistants, are recorded for the whole of the institutions for higher education in the world. In about one-fifth of these, practical work in physical manipulations is not carried on; in the rest, there are about 25,000 students who pass eight hours a week in the laboratories during three semesters. In these four hundred hours passed in the laboratory a student, on the average, performs sixty different experiments, or about two-thirds of the work for which the laboratory makes provision.

SCIENTIFIC SERIALS.

American Journal of Science, October.—An experimental investigation into the existence of free ions in aqueous solutions of electrolytes, by Julius Olsen. The well-known experiment of Ostwald and Nernst, which has been held to prove experimentally the existence of ions in solution, is criticised, and it is held that the conclusion arrived at does not necessarily follow, and that further proof is needed. Experiments are described which show that an electrolyte which has never been acted upon by a current behaves as if it contained particles charged with electricity which are free to move, and these particles have not been produced by a current. This corresponds to the definition of free ions.—On the solution of problems in crystallography by means of graphical methods, based upon spherical and plane trigonometry, by S. L. Penfield. It is shown that with the addition of certain stereographic scales and protractors to a set of ordinary drawing instruments, the lengthy calculations usual in determining the crystallographic constants can be avoided or, as an alternative, checked. Several illustrated examples of the mode of application of this method are given.—The estimation of bromic acid by the direct action of arsenious acid, by F. A. Gooch and J. C. Blake. It is shown that bromates may be satisfactorily estimated by the direct action of arsenious acid, the few apparent discrepancies which were found being traced to the presence of chlorate as an impurity in the bromate.—Solubilities of some carbon compounds, the densities of their solutions, by Clarence L. Speyers. Seven or eight carbon compounds of different types were examined in various solvents, including water, methyl, ethyl and propyl alcohols, chloroform and toluene. The results are compared with those calculated from Schroeder's formula, but the agreement is not good.

Transactions of the American Mathematical Society.—Vol. iii. No. 3 (July).—L. E. Dickson, on the group defined for any given field by the multiplication table of any given finite group. The subject of this paper is much the same as that of Burnside's in *Proc.* L.M.S. xxix.; the results, however, are obtained by a different method, which does not involve the theory of continuous groups. The paper illustrates the importance of Frobenius's discovery of the group determinant. Two examples are given.—O. Stolz, postscript to a previous article on rectification of curves. A comparison is made with Jordan's treatment of the same theory.—O. Bolza, proof of the sufficiency of Jacobi's condition for a permanent sign of the second variation in the so-called isoperimetric problems.—H. E. Hawkes, on hypercomplex number systems. The author develops the methods of Peirce, and shows that they give an enumeration of all systems in less than six units which have moduli in more than one idempotent unit. The systems for five units with two idempotent units are worked out in detail. A discussion of nilpotent systems follows.—W. B. Fite, on metabelian groups.—L. P. Eisenhart, on conjugate rectilinear congruences.—D. N. Lehmer, constructive theory of the unicursal plane cubic by synthetic methods.—L. E. Dickson, on the groups of Steiner in problems of contact (continued from the January number).

Bulletin of the American Mathematical Society (2) ix., No. 1 (October).—O. Bolza, examples in the calculus of variations.—E. R. Hadrick, on the sufficient conditions in the calculus of variations. A convenient summary, based on lectures by Hilbert.—E. B. Wilson, reviews of recent books on mechanics (Föppl, Volkmann, Picard).—E. V. Huntington, on a new edition of Stolz's "Allgemeine Arithmetik," with an account of Peano's definition of number.—E. J. Wilczynski, an obituary notice of Fuchs.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, October 31.—Prof. S. P. Thompson, president, in the chair.—A paper on the existence of a relationship between the spectra of some elements and the squares of their atomic weights, by Dr. W. M. Watts, was read by Prof. Everett. The author has detected two kinds of relation between the spectra of some allied elements. In the first kind, which is illustrated by comparisons between zinc, cadmium and mercury, and also between gallium and indium, the differences between the oscillation frequencies of certain lines of one element are to the differences between the oscillation frequencies of the corresponding lines of another as the squares of their atomic weights. In the second kind, the relation is not between two, but between three spectra, and is illustrated by the trio potassium, rubidium and cæsium, as well as by the trio calcium, strontium and barium. The element of greater atomic weight has the smaller frequency, and, in comparing corresponding lines, one from each of the three spectra, the differences of frequency are proportional to the differences between the squares of the atomic weights. If each of the spectral lines in question is represented by a point the coordinates of which are "frequency" and "square of atomic weight," the three points which represent three corresponding spectral lines will lie on one straight line in the diagram, and these straight lines will be parallel for all the components of a given set of corresponding groups. When a similar mode of plotting by points is employed to exhibit the first kind of relation, the joins of corresponding points meet in a point which lies on the axis of frequencies, in other words, on the line of zero atomic weight. This relation was indicated by Ramage about a year ago as holding for corresponding doublets and triplets.—A paper on the size of atoms was read by Mr. H. V. Ridout. This investigation deals with the size of dissociated atoms, or ions, and the results obtained refer to a dissociated atom as the smallest quantity of matter which can take part in an electrolytic action. The element chosen is hydrogen, and the author concludes that, in round numbers, $114\frac{1}{2}$ million atoms are necessary to form a line one centimetre long. The method employed consists in finding a pair of spheres which would be charged by the quantity of electricity known to be necessary to electrolyse a given quantity of the body under examination—in this case water—to the known difference of potential of its ions. From this the size of the atoms is deduced, subject to certain assumptions enumerated and discussed in the paper. Lord Kelvin remarked that he had often concerned himself with the size of atoms, and pointed out that the value obtained by the author for the diameter of a hydrogen ion was almost exactly one-half of that which he had obtained for the diameter of a molecule of hydrogen. The fact, however, might be a coincidence. He had dealt with a sphere which would have the same effect as a double atom of hydrogen. While avoiding the assumption that atoms are hard and spherical, it was usual to treat them as such for purposes of calculation. The paper was an important one, but there were many assumptions which required looking into. Lord Kelvin said that, in dealing with the subject of atoms, it was necessary to consider the atoms of electricity. The atomic theory of electricity, now almost universally accepted, had been thought of by Faraday and Clerk-Maxwell and definitely proposed by Helmholtz. The atoms of electricity were very much smaller than the atoms of matter, and permeated freely through the spaces occupied by these greater atoms and also freely through space not occupied by them. An atom of electricity in the interior of an atom of matter experienced electric force towards the centre of the atom. We were forced to conclude that every kind of matter had electricity in it, and Lorenz had named electricity as the moving thing in atomic vibrations. If the electrons, or atoms of electricity, succeeded in getting out of the atoms of matter, they proceeded with the velocity of light and the body was radioactive. It was therefore not surprising that some bodies showed radioactive properties, but rather surprising that such properties were not shown by all forms of matter. Our knowledge of this subject,

which originated with the discovery of the Becquerel rays, had been greatly advanced by the experiments carried out at the Cavendish Laboratory, and he had no doubt that in the next two or three years much light would be thrown upon this important matter.—Prof H. L. Callendar exhibited some vacuum calorimeters. Three of the calorimeters were for the determination of the specific heat of mercury, water and steam respectively by the steady-flow method. The fourth was a vacuum-jacketed Bunsen calorimeter. Prof. Callendar gave some details of the instruments and described the method of using them.—Miss A. Everett exhibited some photographs of cross-sections of hollow pencils formed by oblique transmission through an annulus of a lens. The direct rays of an arc light were allowed to pass through an annulus of a convex lens tilted to an angle of 45° with their direction and placed at a distance of about twice its focal length from the arc. The photographic plate was placed at right angles to the beam, and a series of exposures was made at gradually increasing distances from the lens. Two series of photographs were shown, the first series from a plano-convex lens with one annulus and the second from a double convex lens with two annuli.

Zoological Society, November 4.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—Dr. C. W. Andrews gave an account, illustrated by lantern slides, of the palæontological discoveries made by himself and Mr. H. J. L. Beadnell during their recent visit to the Fayum, Egypt.—A communication was read from Mr. R. Shelford dealing with the mimetic insects and spiders of Borneo and Singapore.—Mr. C. Tate Regan read a paper on the classification of the fishes of the suborder Plectognathi.—A communication from Lieut.-Colonel J. M. Fawcett contained notes on the transformations of the butterfly *Papilio dardanus* and the moth *Philampelus megaera*, and descriptions of two new species of moths under the names *Rabdosia clio* and *Dermaleipa daseia*.—Mr. Oldfield Thomas read a paper on the mammals collected by Mr. Edward Degen during his recent expedition to Lake Tsana, Abyssinia.—A communication was read from the Hon. Walter Rothschild, in which he stated his opinion that the elk described by Mr. Lydekker as *Alces bedfordiae* was, if not a valid species, a distinct subspecies, and not a variety as had been supposed by Mr. H. J. Elwes.

CAMBRIDGE.

Philosophical Society, October 27.—Prof. Macalister, president, in the chair.—A case of extreme visceral dislocation, with remarks on the functional interpretation of the agminated glands of the intestine, by Dr. E. Barclay-Smith.—Notes on the genus Liparis, by Mr. J. J. Lister. Among other points, attention was drawn to the difference between the conspicuous satiny-white colouring of the three species *Porthesia chrysorrhaea*, *P. auriflua* and *Liparis salicis* and the quiet buffs, browns and blacks of the other members of the family, conforming closely with their environment; and it was pointed out that there is a considerable body of evidence showing that the conspicuous species are noxious to other animals, both in the larval and adult state, by reason of the urticating properties of the hairs.—Notes on the anatomy of *Macrozamia heteromera*, by Miss A. Robertson.—Further experiments on radio-activity from rain, by Mr. C. T. R. Wilson. In a paper read before this Society on May 5, experiments were described which showed that a vessel, in which freshly fallen rain has been evaporated to dryness, shows radioactive properties lasting for a few hours only. Many samples of freshly fallen rain have since that date been tested both here and at Peebles, and all have shown this effect. The magnitude of the effect obtained from a given quantity of rain has nearly always been of the same order, whether the rain has consisted of large or small drops, and whether it has been collected by day or by night, at the beginning of a shower or after some hours of continuous heavy rainfall. Once, however, during a thunderstorm an abnormally large effect was obtained. The radio-activity is obtained equally well. whether the rain is boiled down in platinum or porcelain vessels. It is not destroyed by porcelain vessels. It is not destroyed by heating the vessel to dull redness; in this, as in other points, it resembles the induced radio-activity obtained on negatively charged wires. From 190 c.c. of rain a precipitate was obtained sufficiently radioactive to increase the ionisation within the testing vessel to about 100 times its normal value; to enter the vessel the rays had to penetrate aluminium about 0·00032 cm. in thickness. The intensity of the radio-activity falls to about one-fourth of its initial value in an hour, like that obtained by evaporation. Similar precipitates formed in tap-water or in rain-water that has stood for twenty-four hours are quite inactive.

MANCHESTER.

Literary and Philosophical Society, November 4.—Mr. Charles Bailey, president, in the chair.—Mr. Francis Jones read a paper on the action of alkalis on glass and on paraffin, in which he pointed out that, while it is generally acknowledged that alkalis in course of time act on glass, there is considerable difference of opinion among chemists as to whether this action interferes with the well-known test for carbon dioxide in air, generally known as Pettenkofer's, but which was first described by Dalton in a paper read before this Society in 1802. Solutions of lime, strontia and baryta of known strength were left in glass bottles at the ordinary temperature for several months, and the strength of each was ascertained from time to time. It was found that the lime water lost strength more rapidly than the others, and that baryta could be kept in glass bottles for a period of twenty months without suffering any material loss in strength. Similar solutions were left in contact with finely divided silica and with powdered glass, and again it was found that lime water acted on these bodies more rapidly than the other two. The action on glass bottles, however, is not so rapid as to prevent any three of these alkaline solutions being used for Pettenkofer's test. It has been suggested that bottles used for this test should be coated with paraffin wax to prevent the contact of the alkaline liquid with the glass, but the author shows that lime, strontia and baryta lose strength in contact with paraffin, the action of baryta being much more energetic than that of either lime or strontia. Some baryta solution in contact with paraffin for five months was very nearly neutral at the end of that period. Consequently, the storing of standard baryta solutions in paraffined bottles is quite inadmissible.—Sir W. H. Bailey exhibited the working model of the switchback centrifugal railway invented and made by Richard Roberts.—Mr. W. E. Hoyle exhibited some coloured photographic lantern slides prepared by the Sanger Shepherd process.

PARIS.

Academy of Sciences, November 3.—M. Bouquet de la Grye in the chair.—On two Trypanosomes of Transvaal cattle, by M. A. Laveran. Details are given of the mode of growth and multiplication of *Tr. Theileri*, the cause of the cattle disease known as Galziekte. Another Trypanosome, found by M. Theiler in the blood of an ox, is regarded by the author as a new species, to which the name of *Tr. transvaaliense* is given.—On the equality of the velocity of propagation of the X-rays and of light in air, by M. R. Blondlot. On the supposition that the velocities of the X-rays and the Hertzian waves are equal, it can be predicted that the reinforcing effect of an X-ray tube upon a spark discharge ought to pass through a maximum for a certain position of the tube with regard to the spark, and this conclusion has been confirmed by experiment. The same hypothesis allows of the calculation in advance of the displacements that the position of the tube corresponding to this maximum ought to undergo in consequence of changes in the conducting wires or in the detonator. This was also confirmed experimentally, one method giving for the ratio of the velocities 0·97 and the other 0·93. The whole of the experimental facts lead to the conclusion that the velocity of propagation of the X-rays is equal to that of the Hertzian waves or of light in air.—On some recent sunsets, by M. Perrotin. The recent sunset glows are compared with the similar ones in 1883, and the hypothesis of their volcanic origin is considered. It is pointed out that the phenomena occurred in the same month in both years, which would tend to suggest that their origin was rather due to meteorological conditions than to after effects of volcanic eruptions.—The analysis of nine specimens of air collected in the galleries of a coal mine, by M. Nestor Gréhaut. The carbonic acid was found to vary between 1·0 and 1·8 per cent., methane between 3·5 and 7·5 per cent., and oxygen between 16·1 and 18 per cent. Attention is drawn to the high percentage of marsh gas, which in three cases was present in sufficient quantity to form an explosive mixture.—On the monographic resolution of the triangle of position for a given latitude, by M. Maurice d'Ocagne.—On uniform transcendentals defined by differential equations of the second order, by M. R. Liouville.

—On the formation of liquid drops and the law of Tate, by MM. A. Leduc and P. Sacerdote. A reply to the criticisms of MM. P. A. Guye and L. Perrot.—Remarks on a recent note by M. Ponsot on the electromotive force of a thermoelectric couple, by M. H. Pellat.—On the electrical resistance of lead sulphide at very low temperatures, by M. Edmond van Aubel. The resistance of the lead sulphide was found to diminish as the temperature was lowered. The experiments were carried out over a range of temperature between the boiling point of liquid air and the ordinary temperature of the room. The results are not in accord with the previous work of Guinchant and Streintz. —On a chlorosulphate of aluminium, by M. A Recoura. The aluminium compound isolated proved to possess the formula $AlSO_4Cl,6H_2O$, analogous with the similar chromium previously described.—On a general method for the preparation of the metallic nitrides, by M. Guntz By heating various metallic chlorides with lithium nitride, several new nitrides have been obtained; among these are two new nitrides of iron having the composition Fe_3N_2 and FeN: chromic chloride gives CrN. By working with lithium hydride instead of the nitride, metallic hydrides are obtained, but in many cases the reaction is so violent that the hydrides formed are decomposed. The conditions necessary to prevent this decomposition are now being studied.—On barium ammonium and barium amide, by M. Mentrel. Barium ammonium is readily formed by the action of barium on ammonia at $-23°$ C., the dissociation pressures being measured for temperatures between $-63°$ and $28°$ C. Nitric oxide is absorbed by this substance at low temperatures, barium hyponitrite being formed; carbon monoxide is also absorbed under similar conditions, forming a new compound, barium carbonyl, $Ba(CO)_2$, a yellow, solid body which decomposes without explosion in contact with air, or on heating. Metallic barium, heated at 280° in a current of dry ammonia, gives barium amide.—On some products of the oxidation of aniline by atmospheric oxygen, by M. C. I. Istrati. By the prolonged action of air on boiling aniline, three new crystalline substances of high molecular weight and unknown constitution were obtained.—On a new albuminoid material extracted from maize, by MM. E. Donard and H. Labbé. The new substance, which is present in maize to the extent of about 4 per cent., and which is best extracted by boiling amyl alcohol, is given the name of maisine. It possesses properties which distinguish it from the albuminoid matters obtained from other cereals.—On the estimation of carbon monoxide and carbonic acid in vitiated air, by M. Ferdinand Jean. An application of the minimetric method to the examination of air, requiring no skilled manipulation in its use.—Researches on the budding of *Rhabdopleura Mormanni*, by MM. C. Vaney and A. Conté.—On the fibrillar continuity of the epithelial cells in the Nebalia, by M. Alphonse Labré.—On vital rhythm, by MM. Vaschide and Cl. Vurpas.

NEW SOUTH WALES.

Royal Society, September 3.—Prof. Warren, president, in the chair.—Languages of some native tribes of Queensland, New South Wales and Victoria, by Mr. R. H. Mathews. This paper dealt fully with the grammatical structure of the speech of the native tribes inhabiting the Murray River along the Victorian frontier, and stretching thence northerly through the central and western districts of New South Wales to the 29th parallel of latitude, and continuing onwards far into Queensland.—(1) Current papers, No. 7; (2) Meteorological notes, by Mr. H. C. Russell, C.M.G., F.R.S.—Meteoric dusts, New South Wales, by Prof Liversidge, F.R.S. The term meteoric dust is used because it is commonly applied to the materials forming the subject of this paper; it is not intended to state that the dusts are necessarily of cosmic or extra-terrestrial origin. The specimens described and exhibited were from Moruya (fell on December 15, 1880); from Uralla (fell on December 14, 1882); from near Broken Hill (fell 1896); from Menindie (fell on June 17, 1899); and Pambula (fell on October 5, 1899). Dust from the roof-beams, and mud from a covered cistern at the University and from the roof of the Observatory, Sydney, all three were collected in 1882. All the dusts are of a reddish colour except those from the University and Observatory, which are grey. The red dusts are mainly siliceous and argillaceous, and look as if they had come from dried-up water-holes; they contain a variety of organic and mineral matters such as might be expected from such a source, and in addition magnetite and metallic iron; the latter contains cobalt and nickel, which seems to indicate that the dusts contain some cosmic or extra-terrestria materials, part of which may have settled down and become mingled with the undoubted superficial terrestrial deposits, and part may have been derived directly from the atmosphere. The University and Observatory dusts also yielded magnetite and metallic iron containing cobalt and nickel, and the University dust yielded particles of gold; the Observatory dust has yet to be tested. The Moruya, Menindie and Barrier red dusts yielded particles of gold; the others have yet to be examined. Fuller information is given in the paper as to the constituents and chemical composition of the dusts, and analyses of volcanic and other dusts for comparison.—A rapid method of estimating lime, by Mr. F. B. Guthrie and Mr. C. R. Barker.

Linnean Society, August 27.—Mr. J. H. Maiden, president, in the chair.—On a new Cryptocarya from Lord Howe Island, by Mr. J. H. Maiden. The "black plum" of Lord Howe Island, the flowers of which have only recently been available, is shown to be new and described under the name *Cryptocarya Gregsoni*. It is also shown that an Elæocarpus occurs on the island, although the material at present available is insufficient to determine the species. Also that the Symplocos on the island, hitherto looked upon as *S. Stawelli*, is in reality new to science, and has been named *S. candelabrum* by Brand. Carl Mez, the monographer of the order Myrsinaceæ, has shown that there is no true Myrsine on the island, but that the genus Rapanea is represented by two species, *R. platystigma*, Mez (*Myrsine platystigma*, F.v.M.) and *R. myrtillina*, Mez, sp.n.—Life-histories of, and notes on, Australian Neuroptera, by Mr. W. W. Froggatt. One species of the family Panorpidæ (*Bitticus australis*, Klug) and twelve of the family Hemerobiidæ are treated of.—Some records of New South Wales mosses, by Mr. W. Forsyth. Eighty-one species or forms are noted. Of these, six forms are new, thirty-nine are additions to the known flora of the State, one is new for Australia, while the remainder are recorded from new or additional localities. The paper concludes with a list of thirty-three species collected in the neighbourhood of the Jenolan caves. — Census Muscorum Australiensium: a classified catalogue of the frondose mosses of Australia and Tasmania, collated from available publications and herbaria, by the Rev. Walter W. Watts and Thomas Whitelegge. Part i., comprising about 530 species.—The ulcer disease (black ophthalmia?) of rainbow trout, by Mr. R. Greig Smith. The ulcer disease of rainbow trout appears to be identical with the brook trout disease of American writers. The disease called black ophthalmia recently occurred at the same time as the ulcer disease in a tank of rainbow trout, but there is reason to believe that these two are not the same disease. From the ulcers, *Micrococcus pyogenes* was isolated. This produces somewhat similar lesions in mammals. The action of the micrococcus in trout appeared to be influenced by the unhealthy conditions to which the fishes had been subjected.

September 24.—Mr. J. H. Maiden, president, in the chair. — Australian fungi, new or unrecorded. Decades i.–ii., by Mr. D. McAlpine.—On a new species of Ardisia from New South Wales, by Mr. R. T. Baker.—Notes on Prosobranchiata. Part i. Lotorium, by Mr. H. Leighton Kesteven. The first portion of the paper is a discussion of the synonymy of the genus and family. The conclusions are in favour of the adoption of Montfort's name Lotorium for the genus, and Harris's Lotoriidæ for the family. The second part deals with the arrangement of the species of the genus.—The bacterial origin of the gums of the arabin group, by Mr. R. Greig Smith. (i) The soluble (arabin) wattle gums. A bacterium (*Bact. acaciae*, n. sp.) was found in pure culture in the tissues of *Acacia binervata* from which gum was exuding. In the laboratory it produced a gum which behaved to reagents, gave the same oxidation products and contained the same constituents, viz. arabinan and galactan, as the natural gum. This soluble gum, and probably all others of a similar nature, are therefore of bacterial origin, a circumstance which had been suggested by the irregular distribution of gum-bearing trees. (ii) The insoluble (metarabin) wattle gums. In company with *Bact. acaciae*, a bacterium (*Bact. metarabinum*, n. sp.) was separated from the bast of *Acacia penninervis* affected with gumming. In artificial culture it formed a gum which swelled with water like the metarabin gums. The gum gives the same reactions and contains the same arabinan-galactan complex as the natural gum. The metarabin is, therefore, the product of this organism.—Revision of the

Australian Curculionidæ belonging to the subfamily Cryptorhynchides, by Mr. Arthur M. Lea.—Descriptions of some new Araneidæ of New South Wales, No. 10, by Mr. W. J. Rainbow. Three new species, referable to the genera Storena, Araneus and Stephanopsis, are described and figured.—Notes on some New South Wales hepatics, by the Rev. W. Walter Watts. Twenty-three species are recorded, the majority of them collected on the Richmond and Brunswick rivers.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), part v. for 1902, contains the following memoirs communicated to the Society :—

July 12 :—W. Voigt : Further contributions to the explanation of the properties of pleochroic crystals. H. Vöchting : On experimental anatomy (of plants).

July 26 :—F. Schmidt : The body-musculature of *Branchiobdella parasita.* W. Kaufmann : The electromagnetic mass of the electron. O. Wallach : Researches (xi.) from the University Chemical Laboratory of Göttingen—(1) on the isomerisation of cyclic hydrocarbons and ketones ; (2) on the transformation of cyclic ketones into bases of nitrogenous ring-systems. W. Voigt : New observations on magneto-optic phenomena in absorption bands.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 13.

MATHEMATICAL SOCIETY, at 5.30.—Address on the Infinite and the Infinitesimal in Mathematical Analysis : Dr. E. W. Hobson.—Ueber den Satz der Gleichheit der Basiswinkel im gleichschenkligen Dreieck : Dr. D. Hilbert.—The Summation of a Certain Series : Prof. A. C. Dixon.—Expansion by Means of Lamé's Functions : Prof. A. C. Dixon.—Sets of Intervals : W. H. Young.—Note on Unclosed Sets of Points defined as the Limits of a Sequence of Closed Sets of Points : W. H. Young.—Wave Propagation in Two Dimensions : Prof. H. Lamb.—The Continuation of Certain Fundamental Powers Series : Prof. M. J. M. Hill.—A Geodesic on a Spheroid and an Associated Ellipse : L. Crawford.—The Propagation of Light in a Uniaxal Crystal : Prof. A. W. Conway.—A New Connection between Legendre Functions and Bessel Functions : E. T. Whittaker.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Presidential Address by Mr. James Swinburne.

FRIDAY, NOVEMBER 14.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Another Form of Micrometer for Measuring Star Positions : H. C Russell.—Ephemeris for Physical Observations of the Moon for 1903 : A. C. D. Crommelin.—Stereoscopic Pictures of Comet Perrine : Max Wolf.—On the Images Formed by a Parabolic Mirror, second paper—Influence on the Measurement and Reduction of a Photograph : H. C. Plummer.—Sur la Précision des Mesures Photographiques : M. Lœwy.—Herschel's Nebulous Regions compared with Photographs taken with the 20-inch Reflector and 5-inch Cooke Lens : Isaac Roberts.—*Possible papers :* On the Proper Motion of Bright Stars Relatively to Faint in the Zones near 30° North Declinations : H. H. Turner.—On a Standard Scale of "Seeing" : Percival Lowell.

PHYSICAL SOCIETY, at 5.—The Theory of the Aluminium Electrode : Dr. W. W. Tayler and J. K. H. Inglis.—A Determination of the Ratio of the Specific Heats at Constant Pressure and at Constant Volume for Air and Steam : W. Makower.

TUESDAY, NOVEMBER 18.

ROYAL STATISTICAL SOCIETY, at 5.30.—Annual Address by the President, Major P. G. Craigie, C.B.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed :* Electric Tramways : C. Hopkinson, B. Hopkinson and E. Talbot.

MINERALOGICAL SOCIETY, at 8.—On some Swiss Minerals : Prof. Lewis.—On Proustite : Mr. Lamplugh.—On Seligmannite and Baumhauerite : Mr. Solly.

ZOOLOGICAL SOCIETY, at 8.30.—On some Pliocene Mammalian Remains from Concud, near Teruel, Spain : Dr. A. Smith Woodward, F.R.S.—On the Birth of an Indian Elephant in the Society's Menagerie : F. E. Beddard, F.R.S.—Note on the Cabul Markhor : R. Lydekker, F.R.S.

WEDNESDAY, NOVEMBER 19.

CHEMICAL SOCIETY, at 5.30.—The Dynamic Isomerism of Thiourea and Ammonium Thiocyanate : J. E. Reynolds and E. A. Werner.—Isomeric partially Racemic Salts containing Quinquevalent Nitrogen ; (1) Part VIII. : Resolution of the Hydrindamine Bromocamphor Sulphonates ; (2) Isomeric Compounds of the Type $NR_1R_2^{\prime}H_3$: F. S. Kipping.—The Synthesis of $\alpha\alpha$-Dimethylglutaric Acid, of β Hydroxy-$\alpha\alpha$-di-methylglutaric Acid, and of the Cis- and Trans- Modifications of $\alpha\alpha$-Dimethylglutaconic Acid : W. H. Perkin, jun., and Miss E. Smith.—A Reaction of some Phenolic Colouring Matters. Part II. : A. G. Perkin and C. R. Wilson.—The Vapour Pressures and Boiling Points of Mixed Liquids. Part II. : S. Young and Miss E. C. Fortey.—(1) The Vapour Pressures and Boiling Points of Mixed Liquids. Part III ; (2) Note on Mixtures of Constant Boiling Point : S. Young.—Note on the Condensation Points of the Thorium and Radium Emanations : E. Rutherford and F. Soddy.—The Oxime of Mesoxamide and some Allied Compounds. Part II. Disubstituted Derivatives : Miss M. A. Whiteley.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—English Climatology, 1881–1900 : F. Campbell Bayard.—The Rainfall of Dominica : C. V. Bellamy.

GEOLOGICAL SOCIETY, at 8.—The Semna Cataract or Rapid of the Nile ; a Study in River-erosion : John Ball.—Geological Notes on the North-West Provinces (Himalayan) of India : Francis J. Stephens.—Tin and Tourmaline : Donald A. MacAlister.

ROYAL MICROSCOPICAL SOCIETY, at 8.—An Electrical Method of taking Microscope Measurements : Dr. Philip E. Shaw.—Demonstration on the Microscope in Fossil Botany : Dr. D. H. Scott, F.R.S.—Demonstration on an Apparatus for obtaining Monochromatic Light with the Mixed Jet : Dr. Edmund J. Spitta.

ENTOMOLOGICAL SOCIETY, at 8.

THURSDAY, NOVEMBER 20.

ROYAL SOCIETY, at 4.30.—*Probable papers :*—Report on the Recent Eruption of the Soufrière in St. Vincent and on a Visit to Mont Pelée in Martinique : Dr. Tempest Anderson and Dr. J. S. Flett.—Contributions to a Theory of the Capillary Electrometer. II. On an Improved Form of Instrument : G. J. Burch, F.R.S.—On the Correlation of the Mental and Physical Characters in Man. Part II. : Dr. Alice Lee, Miss M. A. Lewenz and Prof. K. Pearson, F.R.S.

LINNEAN SOCIETY, at 8.—Digestion in Plants : Prof. Sydney H. Vines, F.R.S.—Relation of Histogenesis to Tissue-Morphology : A. G. Tansley.—Stelar Structure of Schizæa and other Ferns : L. A. Boodle.

FRIDAY, NOVEMBER 21.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Adjourned Discussion upon Captain C. C. Longridge's Paper on Oil Motor Cars of 1902.—And, *time permitting*, Recent Practice in the Design, Construction and Operation of Raw Cane Sugar Factories in the Hawaiian Islands : J. N. S. Williams.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—What is Climatic Disease : Lieut.-Col. A. M. Davies.

CONTENTS.

THURSDAY, NOVEMBER 20, 1902.

BERZELIUS AND WÖHLER.

Briefwechsel zwischen J. Berzelius und F. Wöhler. Im Auftrage der Konigl. Gesellschaft der Wissenschaften zu Göttingen. Mit einem Commentar von J. von Braun. Herausgegeben von O. Wallach. Two vols. Pp. xxii + 717 and pp. 743. (Leipzig : Wilhelm Engelmann, 1901.) Price 2*l.* net.

THE story of the origin of Wöhler's association with erzelius has been told by Wöhler himself in the *Berichte* of the German Chemical Society in one of the most charming autobiographical sketches which have ever enlivened the formal pages of a scientific periodical. Readers of the *Berichte*—and their number is legion—will recall the picture of the young graduate of twenty-three who, with the ardour of the zealous neophyte, had journeyed from the cloisters at Heidelberg to seek light and leading from the great high priest at Stockholm. How with a beating heart he stood before Berzelius's door and rang the bell. How it was opened by a well-clad, portly, vigorous-looking man—none other than Berzelius himself; and how he was led into the laboratory as in a dream, doubting if he was really in the classical place which was the object of his aspirations.

From that memorable meeting sprang a friendship which ended only with Wöhler's death. Berzelius died in 1848, but to the end of his days Wöhler continued to cherish the most affectionate feeling towards his teacher, exhibiting an almost filial piety in regard to his name and fame. He remained to the last what he was wont to sign himself—"Unveränderlich Ihr Wöhler."

Berzelius was an indefatigable letter-writer, and his correspondents were to be found in every country in which chemistry was cultivated. But to none did he unburden himself as he did to Wöhler. For nearly a quarter of a century—that is from 1824 to 1848—scarcely a month passed without an exchange of letters. Those from Berzelius were carefully preserved by Wöhler, who subsequently presented them, some hundreds in number, to the Swedish Academy of Sciences.

It is this correspondence which forms the subject-matter of the volumes before us. Its publication is due to the action of the Royal Society of Sciences of Göttingen, which has desired thereby to commemorate, in connection with the centenary of his birth, the long and valuable service which Wöhler rendered to that body as its secretary. Wöhler had stipulated that the letters from Berzelius which he deposited with the Swedish Academy should not be published before January 1, 1900. This injunction was, no doubt, expedient in view of the character of the letters. The period over which the correspondence extended was a time of stress and strain, not only in politics, but also in science and especially in the science of chemistry. When it began, the influence of Berzelius in the world of chemistry was supreme. Davy, it is true, still lived, but his intellectual activity was well-nigh spent and he was already showing signs of the obscure malady which occasioned his death in 1829. As the years flowed on, Berzelius was made conscious that his influence was waning—steadily undermined by the leaders of chemical thought in Germany and in France, by Liebig and Dumas and their respective followers, who, continually at war with one another, agreed only in disagreeing with Berzelius.

The secretary of the Swedish Academy was, however, a doughty antagonist; very tenacious of his convictions and somewhat insistent in his expression of them, as the pages of his *Jahresberichte* frequently testify. As might be expected, his letters to Wöhler give even more emphatic expression of his opinions, and when his feud with Liebeg culminated in an open breach, he is at no pains to conceal his sense of resentment and irritation. It is this circumstance that determined Wöhler to fix the end of the century as the time that the letters should first be made public—a time so remote from the period to which they relate as to render it reasonably certain that no pain would be occasioned by their publication. In this respect Wöhler was true to himself. He hated contention and was always ready to advise the lion to eat sugar, as he once said to Liebig. His own letters abundantly illustrate this disposition. They are delightful in their spontaneity and directness, in their sobriety of statement, their unfailing charity and the quiet, delicate humour by which they are constantly illumined. Berzelius evidently set considerable store by them, and they were preserved with no less care than his own. They were ultimately given by the Baroness Berzelius to the Stockholm Academy, and were by it placed at the disposal of the Göttingen Society. With a few exceptions, Berzelius's letters were written in Swedish, and have been rendered into German for the purpose of this work by Frau Prof. Schering, of Göttingen, the daughter of the Swedish Prof. Malmsten. Those from Wöhler have been arranged for publication by his daughter, Frl. Emilie Wöhler.

To the historian of chemistry, this correspondence is of singular value and interest, inasmuch as it stretches over the period which saw the rise of modern chemical theory. Throughout it are constant references to the ideas and hypotheses which gradually developed into the chemical doctrine of the middle part of the nineteenth century—of the period we associate with the names of Liebig and Wöhler, Magnus, Mitscherlich, Rose and Dumas. In some of the letters, we have accounts of discoveries and inventions which mark epochs, or points of departure, in chemical progress. Thus in one of the letters Wöhler describes in detail Liebig's newly-invented method of organic analysis, with sketches of the potash-bulbs, of the mode of making the india-rubber joints and of the charcoal furnace or chauffer. Berzelius was, as is evident from his reply, greatly impressed with the value and importance of the new method, and his genius for manipulative chemistry was immediately exercised in suggestions which he trusts may be improvements. Wöhler also sent to Stockholm one of the earliest accounts of Will and Varrentrapp's method of determining nitrogen. Indeed, we frequently meet with accounts, occasionally illustrated by rough sketches, of manipulative methods and pieces of apparatus which are nowadays to be met with in all laboratories. We have accounts sometimes from the discoverers themselves of metaphosphoric acid, thoria, hippuric acid, vanadium, tellurium, chloroform, chloral; of the isolation of

aluminium; of the synthesis of urea and the mode of preparation of a host of substances, organic and inorganic, of which the times were fertile. Very interesting and instructive, too, are the references made by the correspondents to the work of their contemporaries. Thus Berzelius keeps Wöhler informed of what Mosander is doing, and of the researches of his pupils Dahlström, Sefström, Mitscherlich, Magnus and Johnston; whilst Wöhler in his turn tells, for example, what he knows of Liebig's work, of the progress of Bunsen's investigation of the fuming liquor of Cadet, or sends short notices of what the Göttingen students, under the stimulus of his direction, are turning out.

Wöhler was an excellent draughtsman. Some of his drawings are as amusing as they are clever. Not less excellent are his verbal sketches, as may be seen in the admirable descriptions he sends Berzelius of his experiences of Paris and of the French chemists of the day—what Berzelius styles "die amüsanten Plaudereien ueber die Babylonischen Chemiker"—Gay-Lussac, Thénard, Dulong, Ampère, Chevreul, Robiquet, Bussy, Boussingault, Dumas, Pelouze. He thus, for example, describes Ampère:—

"Ampère. Ein Original wie es wohl wenige mehr gibt. Ein ziemlich grosser alter Mann, vom Alter etwas gebückt mit dicker hängender Unterlippe, ziemlich zahnlos, mit hervorstehenden, stier blickenden Augen, eine Perrücke, die hier und da den Kahlkopf durchblicken lässt, gekleidet in schwarzem Frack, der sehr alt und abgeschabt ist, und die Wäsche stets braun von Schnupftabak, den er in zwei Dosen mit sich führt. Dessen ungeachtet war mir dieser Mann einer der merkwürdigsten und respectabelsten. Den Neckereien und Witzen, die er von den anderen alten, namentlich von Arago und Thénard, zu erdulden hat, entgegnet er mit einer grossen Gutmüthigkeit und nicht selten mit komischem Witz. Nichts verdriest ihn, und er bleibt stets in demselben guten Humor. Er ist ohne Zweifel einer der tiefsten speculativen Köpfe und scheint eine ungeheuere allgemeine Gelehrsamkeit zu besitzen. Er ist selbst in den neuesten chemischen Entdeckungen ganz im Detail zu Haus."

Equally interesting, and no less characteristic, is his account of Dumas, whom he styles "der fleissigste und geistvollste der jüngeren franz. Chemiker." His description of the "kleiner, magerer Kerl" is too long to quote here, but it caused Berzelius to say in reply, "Ich möchte unendlich gern Dumas Bekanntschaft machen."

Had space permitted, we should have liked to have given a number of extracts in order to illustrate the wealth of information of historical value which is scattered throughout this correspondence. There is not a dull page in the two volumes. At times, indeed, the letters are of the greatest interest, and not unfrequently they are most amusing.

They have been carefully edited, and the commentary and foot-notes supplied by Dr. von Braun serve to elucidate many points which would otherwise be obscure. We congratulate Prof. Wallach on the production of a work which is a striking monument to the genius of two men of whom it may be said, as Liebig said of his own friendship with one of them, that now they are dead and mouldering, the ties which united them in life still hold them together in the memory of men as faithful workers who zealously laboured in the same field, linked together in the closest friendship. T. E. T.

A BIOLOGICAL PHILOSOPHER.

Die organischen Regulationen. Vorbereitungen zu einer Theorie des Lebens. Von Hans Driesch. Pp. xv+228. (Leipzig: Engelmann, 1901.) Price 3s. 6d. net.

DR. HANS DRIESCH is well known for his experimental contributions to "developmental mechanics" and as a man of strenuous "begriffskritische Thätigkeit." He is the author of a number of essays which give their readers good exercise in intellectual mastication, and the book before us is another hard nut. We are in entire sympathy with his endeavour after an exact criticism of biological categories and with his ideal of a "truly scientific biology" with thought-out and unified formulæ; we suspect there is some justification for his reproach that there is far too little "reines Nachdenken" in the tents of the biologists; and we share his hope that "in the future the naturalist will be more of a philosopher and the philosopher more of a naturalist"; but, to be frank, we wish that the author, who writes much, could see his way to write a little more clearly. We do not, of course, expect a philosophical criticism of biological categories to read like a novel, but we object to a book where the difficulty of individual sentences intermittently inhibits us in our effort to appreciate the general argument. It may be that biologists do not quite realise how much they are losing by not reading Driesch's essays; but does Driesch realise how much he is losing by ignoring the limitations of human faculty and of a busy biologist's leisure? We have to rub up our mathematics to understand Karl Pearson, we have to learn statistical methods, we are reminded that "nemo physiologus nisi psychologus," we have perforce to be palæontological, our attention to chemistry and physics is essential, we are told that some acquaintance with crystallography, mechanics and meteorology will not be amiss, and so on. Thus a book which demands for its due appreciation no small amount of familiarity with philosophical terms and methods comes almost as the last straw to break the back which mis-education has weakened. We remember, however, that Driesch's essay is intended for philosophers as well as for biologists, and we hope that the former will discover a limpid stream in what seems to us a rather turbid flow, broken here and there by luminous rapid rushes.

The work before us is one of a series of "studies" ("Vorbereitungen") for a theory of life. It deals with "organic regulations," *i.e.* with those vital phenomena which may be roughly compared to the action of a safety-valve in a steam-engine—a compensatory action annulling the disturbing factor and restoring equilibrium. It does not, however, include those coordinated locomotor regulations which we call instinctive adjustments, or those which occur after extirpation-experiments on central nerve-organs. The author has abundant material without these. In studying "organic regulations," which he does with abundance of concrete instances, the author has had a two-fold aim—(*a*) that of giving impulse to research by showing in the strong light of his criticism the gaps in the scientific structure, and (*b*) of advancing a step or two towards "a truly scientific biology." This improved biology will have its dominant concepts more thoroughly thought out and more adequately harmonised,

and it will give prominence to what is, after all, the essential feature in life, the feature studied in Driesch's "Regulatorik"—a supplement to "Organisatorik"! As this scientific biology progresses, a recognition of the need for a "dynamic teleology" will become plain, and everything will become clearer before the open secret of "the autonomy of vital processes." The plan of the book is clear. Part A. is devoted to a descriptive and critical exposition of facts, based especially on the work of Pfeffer and Goebel, Dieudonné and Herbst, and dealing with phenomena like those of immunity, functional and structural adaptations, regeneration, and so on. Part B. includes a definition of the concept of "regulation," a classification of "regulations," an analysis of the process of regulation and an exposition of the two lines of argument which lead to a recognition of the autonomy of vital processes. Part iii. is more technically philosophical, dealing with "Denknothwendigkeit," "Causalität," &c. —"den reinen Erkenntnisskritikern empfohlen."

Let us try in more detail to illustrate the drift of this difficult book. Pfeffer has shown that certain fungi, supplied simultaneously with several organic substances, almost always assimilate first that which has the greatest nutritive value, and go on to the second best only after they have exhausted the optimum. In scarcity of food and of oxygen, many living creatures illustrate an adaptive regulation of their metabolism. There is strong evidence in support of the conclusion that various living creatures can by the production of a specific antitoxin render themselves relatively immune to a specific poison. We have given three examples which may hint at what Driesch means by regulations in metabolism ("*Stoffwechselregulationen*").

Similarly, we all know that the CO_2-content of the blood has a regulative effect on the blood-pressure and on the respiratory movements, that cold weather has a regulative influence on the peripheral circulation which lessens the loss of heat, that plants show a regulative transpiratory response to altered conditions of humidity, that a fungus-cell will save itself from plasmolysis in a too-concentrated solution by the increased production of osmotically-active substances (acids), that our intestinal and renal cells behave not less effectively, and that, altogether apart from brain or eyes, as in the case of a decapitated Planarian, there are adaptive responses to light and other stimuli. These examples may serve to suggest what Driesch means by functional regulations ("*Energetische regulationen*").

It is well known that the leaves of the same kind of plant may have different mesophyll arrangement in different conditions, and that the new circumstances may be said to evoke their own corrective; that the structural adjustments of the same amphibious plant to thoroughly aquatic or to mainly terrestrial life are effective in both instances; and that many kinds of creatures, both animal and vegetable, adapt themselves to conditions of desiccation. These are a few simple examples of what Driesch means by regulative structural adaptations ("*Morphologische Anpassungen an Aüsseres*").

If the top of a conifer be destroyed, a dorso-ventrally disposed side branch may rise upright; if a crab's leg or a lizard's tail is lost, another may be made; a fragment of an animal, even of an embryo, may regrow the whole; a Hydra's tentacles may, in case of need, be, as it were, resmelted into body-substance; the lost lens of a newt may be replaced by adventitious growth from the iris. In short, the author discusses the whole subject of regeneration (recrescence and reparation), and finds therein abundant evidence of "regulation" ("*Restitutionen oder Wiederherstellungsregulationen*").

The four German phrases noted above in italics are the titles of the first four chapters of the book, but we have not been able to give more than a hint of the breadth of the author's survey of facts. We would in particular direct attention to the valuable essay on regeneration included in chapter iv.

Part A. is relatively plain sailing, for there we are dealing with more or less familiar facts, but in Part B.—the theoretischer Theil—we soon get into rough water. There are many sentences which we cannot even pretend to understand. We are first supplied with a definition of the concept "regulation."

"A regulation is a process, or a change in a process, occurring in a living organism whereby some disturbance of its previous 'normal' condition is wholly or partially, directly or indirectly, compensated, and the 'normal' condition, or at least an approximation to it, restored."

By an abstraction, which, if we understand it aright, seems only verbal, Driesch distinguishes two chief kinds of regulations—organisational and adaptive; the former restore disturbed organisation, the latter restore disturbed adaptiveness. The author restores our confidence, however, by admitting that organisation and adaptation interpenetrate one another ("durchdringen sich"). Then follows an elaborate classified catalogue of "regulations."

We have read with interest and instruction the chapter on the course of a regulative process.

"The primary stimulus in regulations consists in a removal of parts or in a disturbance of function. It may coincide locally with the effect, or it may affect the organism quite generally, in which case the localisation of the effect in relation to that of the stimulus is 'specificirt,' or it may have a localisation other than that of the effect. In the last case, mediations ('Vermittelungen') of the primary stimulus become necessary, which sometimes perhaps express themselves materially ('stofflich'), but usually operate in a quite unknown manner. They thus produce the secondary or true stimulus, while in the other cases of relation between localisation of stimulus and localisation of regulation the primary stimulus was also the true one. Regulations, whether functional or formative, presuppose secondary prospective potencies, in contrast to the primary potencies, which form the basis of the normal series of occurrences ('Geschehen'). In the diversity of the specific distribution and specific content of these potencies, we find, at the same time, the limitations of the regulative process ('Geschehen'); since every regulative process is at the same time a reaction-process, its 'specificity' has at the same time the general physiological and morphological characteristics of a reaction-process; but it has besides special teleological characteristics always of a particular kind. The time at which a regulation begins to operate we call the 'Regulationsmoment.'"

We have tried to translate this "Rückblick" on the analysis of regulation-processes, and we must apologise for the awkwardness of our translation. We hope, however, that it will suggest the luminosity of Hans Driesch's

writings and the absurdly easy-going way in which many physiologists deal with that adaptiveness of response which is the very essence of life.

The kernel of the book is to be found in chapters vi. and vii. of the second part, but the kernel is surrounded by a hard stone. These two chapters (which Driesch says "ich ganz besonders als mein Eigenthum ansehe") contain an analytic discussion of "form-regulations," an excursus on the problem of heredity and an exposition of the two proofs of the autonomy of vital processes Evidences of the falsity of Weismann's theory of development and theory of heredity—both of which Driesch condemns as hopelessly materialistic—are thrown in. The differentiation of harmoniously-equipotential systems is the one foundation of "vitalism"; the existence and genesis of equipotential systems with complex potencies is the other. Whether we study the development of a sea-urchin ovum or the growth of a Tubularian fragment, or regeneration in Planarians, or the potencies of cambium, we are brought face to face with regulative phenomena which put the most elaborate "machine-theory" of life out of court and lead us to recognise "the autonomy of vital processes." So far as we understand, it simply comes to this, that the formulæ of chemistry and physics, as at present conceived, seem quite inadequate for the scientific interpretation of the facts of life.

J. ARTHUR THOMSON.

AN INDIAN POCKET-FLORA.

Forest Flora of the School Circle, N.-W.P. Being a Descriptive List of the Indigenous Woody Plants of the Saharanpur and Dehra Dún Districts and the Adjoining Portion of the Tehri-Garhwal State in the North-Western Provinces, with Analyses. Compiled for the Use of the Students of the Imperial Forest School, Dehra Dún, by Upendranath Kanjilal, Extra-Assistant Conservator of Forests. (Calcutta: Office of the Superintendent of Government Printing, India, 1901.) Price 2*s*.

"I BELIEVE this to be the first botanical work of any importance which has ever been prepared by a native of India, and the Imperial Forest School may well be proud of having educated at least one native gentleman who has taken up botany as a study and botanical work as a labour of love." So writes Mr. J. S. Gamble in his introduction to this useful pocket-flora, which is designed for the use of Indian students of forestry.

Following upon this introduction, in succession are the author's preface, a brief glossary of botanical terms, a general analytical table of the Phanerogamia, an analytical key to the natural orders, accounts of the natural orders, with analytical keys to the genera and species, and descriptions of the latter, and, finally, indices to the European, vernacular and botanical names.

Even with the great aid of Sir Joseph Hooker's "Flora of British India" and Sir Dietrich Brandis's "Forest Flora of the North-West Province," it was no light undertaking to prepare a pocket-flora containing the required information. The author may, however, be congratulated upon his execution of the task.

The greatest difficulty in compiling this work was, doubtless, to select the subject-matter in such a manner as to keep the book small in size, yet devoid of vagueness. The author has elected to give rather full descriptions of the species, even including their vernacular names, habitats, habits, timber structure, uses, times of flowering, fruiting and leaf-shedding. The compression, and hence uncertainty, has therefore fallen upon the steps leading to the determination of the species, and particularly upon the glossary and analytical keys. The result is that the work, though extremely useful as a pocket reminder and aid to students (for whom it is intended), and for others possessing other guides, could not be easily employed by a novice or amateur for the determination of species.

The glossary, in addition to being somewhat too compressed, is occasionally somewhat obsolete, so that some of the definitions, for instance "cone," "endosperm," "lenticel," "moniliform," "prickle," "symmetrical," are scarcely satisfactory. The term "gregarious," though frequently used in the book, is not explained. In regard to this term, its continued use in botanical works is somewhat unfortunate when the more accurate term "social" is available.

The very compressed table showing the general scheme of classification is disfigured by one unnecessary and serious error; it divides flowering plants into Monocotyledons and Dicotyledons, and the latter again into Angiosperms and Gymnosperms!

In the key to the natural orders, the diagnostic characters given evidently refer in particular to the representatives in the flora described; for instance, the features given in reference to the Dipterocarpaceæ are, that they belong to the Polypetalæ, Thalamifloræ, and possess a valvate, irregular calyx adnate to the ovary and enlarged in the fruit; again, the Tiliaceæ are distinguished from the Sterculiaceæ by the free condition of their calyx. It is in this analytical table that some additions would be especially useful, especially such as facilitate identification in the absence of fruits.

Similar additions might be made in the analytical keys to genera and species. To take a specific case, the seven genera of Coniferæ—Taxus, Cupressus, Juniperus, Pinus, Cedrus, Picea, Abies—are distinguished from one another in this book primarily by the structure of their fruits. A novice having a specimen without fruits consequently could not take the first step towards identifying his plant. Yet it is very easy to give a brief key showing how to distinguish these seven genera by the arrangement and form of their leaves. In this particular instance, too, an especially good observer might well be puzzled by the distinction in the analytical key between Picea and Abies, the leaves of the former being described as acicular and multifarious, whilst those of the latter are said to be flat and bifarious.

As regards the get-up and printing of the book, great carelessness has been exhibited in the printing and possibly in the revision of proof; ugly curved lines of words and displaced letters occur, but misprints abound in glossary, tables, text, and in names of all kinds.

The defects of the book, therefore, are for the most part minor or matters of opinion, whereas its merits are great; and, as Mr. Gamble writes, "I am confident

that . . . this Flora will prove valuable to many successive classes of forest students and many successive forest officers whose duties may call them to the beautiful forests of the Dún and the splendid scenery of the adjoining Himalayan Mountains."

THE LAWS OF GEOGRAPHY.

Les Lois de la Géographie. 1er. Étude. Par Carlos de Mello. Pp. viii + 360. (Berlin: R. Friedländer und Sohn, 1902.) Price 10 marks.

SENHOR CARLOS DE MELLO, professor of geography at San Paulo, wields the pen of a ready and fearless writer, for he prefaces his volume of 360 pages on the laws of geography with the statement that it was written in two months, and the regret that it is consequently neither so clear nor so full as it might otherwise have been. "A short bibliography," he says, "concludes the work"; but since the bibliography occupies 224 pp. and the rest of the work only 136, we are inclined to think that the fact could be better expressed otherwise. Dedicated in Portuguese, written in French, printed and published in Germany, it is evident that the "laws of geography" are superior to the trammels of nationality or language. We were, in fact, unfavourably impressed by the preface, and it required some effort to approach the text with an open mind. On reading the chapters it soon became apparent that, however hastily the book was written, its preparation had required and had received years of thought, and study and wide reading. Even in the minor details of correct transcription of foreign names and the titles of publications, quite exceptional care must have been taken, for we have rarely seen a book so full of detail equally free from typographical errors.

The first of the "laws of geography" to be discussed is the law of asymmetry. It is pointed out how rarely parallelism is found in the larger features of the globe, how invariably (except in the case of Africa) a continent occupies a non-central position on its continental block, and how the relief of the continent itself displays a conspicuous dissymmetry, as in the position of the great plateaus of America. From this principle a series of laws of contrasts and harmonies is deduced with much ingenuity and confirmed to a considerable extent by the citation of examples. But even by the device of adopting asymmetry instead of symmetry as the standard of reference, it is impossible to avoid exceptions and contradictions. For example, in the "law of contrasts" which declares that the northern continents extend in the direction of the parallels and the southern continents in the direction of the meridians, the anomalous case of Australia is passed over without remark. We cannot help feeling that the author may possibly hold too precise and mathematical a view of symmetry in regard to the great features of the Earth's crust. It seems to us that broad features should be looked at broadly, and that on doing so the Earth's surface exhibits a rough symmetry in the alternation of height and hollow and the interlocking of ocean and continent. To a closer view, of course, the roughness appears more remarkable than the symmetry, but we have a suspicion that the symmetry is there as a dominant fact and the asymmetry only as a detail. We are by no means sure, however, that the author has not started with the idea of the symmetry of terrestrial features as self-evident, and therefore devotes his whole attention to the rectification of the broad principle in details.

Part ii. deals with the laws of mutual dependence of terrestrial forms, and considers the cases of the relation of rivers to valleys and of continents to oceans. It presents a number of relationships arrived at by many authors whose works were often separated by considerable intervals of time. Some of these have been accepted and incorporated in current views, others have been passed over and forgotten. We have not space to refer critically to these, or to inquire how far they agree with or contradict the recent systematic discussion of the relation of rivers to their valleys which has culminated in the geographical cycle of Prof. Davis; but we cannot let pass the opportunity of reviewing this thoughtful summary of a part of geographical theory without inquiring why it is that so much of the work of geographical theorists has passed unproductively into oblivion. The reason may perhaps be that an original mind devoted to purely geographical questions has only arisen at long intervals; the work of the predecessor has been forgotten or absorbed as a detail in other sciences before the successor has made himself heard. It may be that this is due to the absence from geography of the numerous less original workers who are attracted to the study of other sciences by prospects of gain, and, while unable to advance the science themselves, at least hand on the torch without extinction.

Whether this be so or not, the fact is beyond dispute that geography has not made the progress that it should have done; and, more particularly in this country, the geographer as such is scarcely recognised. Geographical questions have so frequently been treated as incidents in the course of geological, botanical, zoological or historical investigations that even the scientific world hesitates to accept geography as a subject deserving of the whole attention of a competent man. There are signs of improvement in this respect, it is true, and any improvement is matter for satisfaction. There is room for many books of the type of Prof. de Mello's, and it would be well if such books commanded many readers. The sympathetic attitude of the ancient universities to geography is a gratifying and hopeful circumstance, almost compensating for the inadequate or even retrograde steps of the newer academic centres.

H. R. M.

OUR BOOK SHELF.

The Elements of Electrical Engineering. A First Year's Course for Students. By Tyson Sewell, A.I.E.E. Pp. xi + 332. (London: Crosby Lockwood and Son, 1902.) Price 7*s.* 6*d.* net.

THIS book, which is based upon courses of lectures delivered by the author, is primarily designed for students attending evening or other courses at the polytechnics. The course of lectures is more or less complete in itself, the necessary elementary theory being by no means neglected; the author, indeed, advises students to take a concurrent course in the scientific side of the subject, but such as are unfortunately unable to spare the necessary time will not, we think, find much in this book

which is beyond their comprehension. Undoubtedly, for a thorough training in electrical engineering the practical and theoretical sides of the subject must receive equal attention, but not all students can attend institutions where this is to be obtained. Many have of necessity to be satisfied with some sort of compromise, and one welcomes a book which is sound in its treatment and is admirably calculated to give such students the knowledge and information they most require.

Selection of some sort, when dealing with so large a subject, is of course necessary; the author has, we think, made a wise choice in the branches with which he deals and in the manner in which he treats them. These include, in addition to the general principles underlying the subject, batteries, accumulators, measuring instruments and supply meters, arc and incandescent lamps, and the continuous-current dynamo and motor. Particular apparatus is only described when it illustrates the general principles. Perhaps in a few instances there is a little too much detail, as, for example, in the description of the recording mechanisms used in meters. We would gladly see some of this matter omitted, and such branches as telegraphy, telephony and electro-chemistry treated on broad lines instead. Mr. Sewell has the power of clear exposition, and has succeeded well in avoiding too mathematical treatment; the illustrations and diagrams are excellent. M. S.

The Force of Mind: or, the Mental Factor in Medicine. By A. T. Schofield, M.D., M.R.C.S., &c. Pp. xiv + 309. (London: J. and A. Churchill, 1902.) Price 5s. net.

IN this book, which is written for medical practitioners, Dr. Schofield appeals for a fuller recognition of the influence of the "mind" in causing and in curing disease of the body, and urges medical men to work for the reclamation of those waste and unmapped regions in which the religious fanatic and the quack doctor have hitherto been allowed to reign, occasionally producing, among much that is harmful, remarkable cures. He would have the subject taught and studied in the hospitals and great medical schools as a part of the regular curriculum of every medical student. There can be no doubt that the reforms advocated are much needed and that Dr. Schofield performs a useful service in thus pointing out the weak and neglected side of modern medicine. The author supports his contentions with many quotations from high authorities, both ancient and modern, and by the citation of numerous cases, and gives from his own experience many practical hints that should be valuable to practitioners. From the point of view of the psychologist, the book is vitiated throughout by the insistence upon the part supposed to be played by "the unconscious mind." This seems to be a figment similar in function to von Hartmann's "unconscious," *i.e.* it is a hypothetical agent to the activity of which is assigned all that is obscure and difficult of explanation in the workings of the nervous system. It is a radically vicious hypothesis because it is one that tends to baffle rather than to quicken the impulse to research. We are told that the phrase is not used merely to cover the more complex workings of the nervous system that are not accompanied by consciousness, and no reasons are assigned for rejecting this, which may now be called the generally accepted and intelligible view of the matter. The author seeks to support his position by quoting Dr. Bastian's plea, "Let us make mind include all unconscious nerve actions," and in so doing reveals the dire confusion of his own thoughts on this subject. He good-naturedly pokes fun at those who objectify "Nature" as a healing agent and then commits the same error, replacing "Nature" by the *vis medicatrix naturae*, which he identifies with the unconscious mind, and thus commits himself to the somewhat absurd dogma that such remedial processes as compensatory hypertrophy of the heart and phagocytosis are manifestations of the power of "the unconscious mind." Unless it can be shown, as at present it cannot be, that nervous activities and conscious processes together are inadequate to the explanation of all the facts of our mental life, the assumption of a third mysterious agent, call it "the unconscious mind" or "subconsciousness" or what you will, is much to be deprecated. W. McD.

Introductory Chemistry for Intermediate Schools. By Lionel M. Jones, B.Sc., A.R.C.Sc.(Lond.) Pp. vii + 195. (London: Macmillan and Co., Ltd.) Price 2s.

THE standard of this book is suitable for the junior classes of intermediate and secondary schools in which chemistry is used as a form subject, and the matter in it covers almost the same ground as that in the chemical part of Perkin and Lean's "Introduction to Chemistry and Physics." The treatment is rather different, as the historical side is not mentioned. The students are expected to have been taken through some course in physics or experimental science before they begin this course. It is important that they should have done so, as they are supposed to understand the balance, to weigh to milligrammes and to know the meaning of many physical terms.

The book opens with chapters on the description of bodies. Much attention should be given to this, as in a recent examination, when a fragment of Iceland spar was given for description, only a very small percentage of candidates recognised that definite shape was characteristic of the substance. Then follow chapters on simple operations, solution, evaporation, distillation. Afterwards come chapters on rusting, combustion, oxygen, hydrogen, chalk, coal and coal-gas, salt and salt-gas, and finally on acids and bases.

Some of the methods appear to us to be too elaborate for young children. There is, for instance, the complicated aspirator, which experience has taught the present writer is hardly ever clearly grasped. The correction for pressure is always a difficult point. Again, the students should never be allowed to make statements such as "1 litre of hydrogen weighs 0·09 gm." or "density of chalk-gas 0·00198 gm. per c.c." without stating definitely the temperature and pressure at which the weight or density has been ascertained.

We should have liked to have seen more attention given to the indestructibility and conservation of matter. This principle of chemistry cannot be grasped too early. Many of the elementary experiments are conducted with its tacit assumption, and we think it should be pointed out to the student. S. S.

Next to the Ground; Chronicles of a Country Side. By Martha McCullock Williams. Pp. xii + 386. (London: Heinemann, 1902.)

IN this dainty little volume, the author affords English readers a most interesting series of glimpses of the charms and passing events of everyday country life in the United States, after the fashion which so many writers have made familiar in England. A close observer of nature, and evidently imbued with the spirit that everything has an interest of its own, if looked at in the proper light, the author has hit upon a congenial subject, and treated it in a manner which affords an excellent example of the best style of "nature-teaching." The scene is laid in a southern county lying to the westward of the Alleghanies and eastward of the Mississippi, nearly midway between the mountains and the river; and whether describing ploughing with mules or oxen, discoursing of the quail, the partridge or the opossum, discussing shooting and fox-hunting or writing on horses, cows and pigs, the author is equally at home and equally interesting. Some of the information given, such

as the fact that the Derby is a race for three-year-olds (p. 255) and that female foxes are properly called vixens (p. 305) is perhaps somewhat superfluous, for English readers at any rate; and we rather fail to see why pigs are called cousins of opossums (p. 149).

To the naturalist, the most interesting chapters are those on wasps and ants, the "possum," quail and partridge, and insects generally, the account of the habits of the opossum being especially good. In the chapte on fox-hunting, the author confirms the statement of other writers that the so-called red fox (the American representative of the European species) cannot be run down without a relay of dogs, or, as we should say, hounds. Whether, however, this is due to the greater speed of American foxes or the inferior pace of American hounds remains to be told. In teaching people how much is to be learnt from the intelligent observation of ordinary surroundings, the book before us is clearly a step in the right direction. R. L.

L'Age de la Pierre. By G. Rivière. "Bibliothèque d'Histoire et de Géographie universelles." Pp. 183. (Paris: Schleicher Frères.) Price 2 francs.

IN this book we have a popular account of the Stone age following the traditional lines of French archæology. The author does not pay much attention to any discoveries out of France, but the French evidence being so complete this does not matter very much, especially as the book is not intended for students. The transition between the Palæolithic and Neolithic ages is recognised, and the author brings out clearly the culture of the immigrant Neolithic brachycephals. The statement on p. 136 that "certain peoples of Oceania still use very similar sticks [to the curved throw-stick of Egypt] which they call boomerang" is inexcusably vague. A description of megalithic monuments closes the account of the Neolithic age. The last chapter deals briefly with trepanation as a surgical method in Neolithic times. The author still employs the absurd term "bâtons de commandement" for the carved perforated antlers found in the caves; surely he must have known of the conclusive paper read by O. Schoetensack before the Congrès International d'Anthropologie et d'Archéologie at Paris in 1900, in which the author demonstrated their similarity to the bone dress fasteners of the Eskimo. In addition to twenty-six figures in the text, there are four half-tone plates, three from the paintings of Jamin and one from Cormon, which illustrate in a dramatic manner various incidents in the life of the men of the Stone age.

Flora of the Liverpool District. By C. T. Green. Pp. xii + 207. (Liverpool: D. Marples and Co., 1902.) Price 5*s.* net.

THE present work replaces a previous "Flora of Liverpool," which was originally published in 1872 and to which, later on, appendices were added. The revision of previous records and the compilation of recent data have been undertaken by members of the Liverpool Naturalists' Field Club, under the direction of Dr. Green. An original feature of the book consists of illustrations specially drawn by Miss E. M. Wood. These are for the most part characteristic and lifelike, and the figures of certain less common species such as *Ranunculus Lenormandi*, *Viola carpatica*, *Juncus supinus* and others are very useful, but in many instances the important features of the plant are omitted, or at any rate not emphasised, *e.g.* the root of *Lathyrus macrorhizus*. In the case of localities where plants are now extinct, as, for instance, Oxton Heath, it would have been well to notify this more definitely. It will be observed that comparatively recent strangers are being admitted, notably *Lycium barbarum*, while *Solanum rostratum* represents a quite modern American invasion. The geological chapter does not serve to dispel the impression that the book is too much of a dry catalogue, and even the submerged forest at Leasowe receives but a brief mention.

Examples in Algebra. By C. O. Tuckey, B.A. Pp. viii + 178. (London: Bell and Sons.)

IN making this collection, Mr. Tuckey has kept in mind the recommendations of the committee on the teaching of mathematics appointed by the Mathematical Association, and the result is seen in various welcome innovations. Thus, for instance, exercises on the use of graphs are given, some at quite an early stage; there are problems to show the application of algebra to geometry, mensuration and elementary physics, and so on. Checks on accuracy are frequently suggested, and there are numerous questions to be answered orally. Particularly good sets of questions are those on "Formulæ" (p. 23) and "On the Use of Theory of Form as Check" (p. 93). Merely artificial conundrums are happily rare; the worst we have noticed is "Simplify $\sum_{abc} \frac{1}{1 + x^{a-b} + x^{a-c}}$." Undoubtedly this is a very good collection, which may be recommended without reservation.

Children's Gardens. By the Hon. Mrs. Evelyn Cecil (Alicia Amherst). Pp. xv + 212; with illustrations (London: Macmillan and Co., Ltd., 1902.) Price 6*s.*

THE object of this daintily produced volume, with its profusion of beautiful illustrations, is to teach children enough about gardening to enable them to find pleasure and profit in the study and cultivation of plants. The book is written in a simple, practical way, and should be of real assistance to those who are able to indulge their taste for horticulture without too much attention to expense. Judging from the style of the book, we should say that the author will succeed in winning and retaining the interest of young children, who will, by the way, find occupation for the winter months as well as for the brighter seasons of the year. Directions are given as to how to utilise the leisure hours of winter in reading about the plants, in manufacturing garden seats and so on, for use in the garden during the days of summer. Altogether a pretty gift book.

School of the Woods: some Life Studies of Animal Instincts and Animal Training. By William J. Long. Illustrated by Charles Copeland. Pp. xiii + 364. (Boston, U.S.A., and London: Ginn and Co., 1902.) Price 7*s.* 6*d.*

MR. LONG believes that an animal's success or failure in the ceaseless struggle for life depends, not upon instinct, but upon the kind of training which the animal receives from its mother. He has written most of the sketches contained in this attractive volume in the woods, with the subjects themselves living just outside his tent door. The result is that we are provided with an interesting book which will go a long way to make all who read it lovers of nature and sympathetic, intelligent observers of animal life. Mr. Copeland's excellent pictures will help very much to make the book a favourite with children.

Macmillan's Short Geography of the World. A New Handbook for Teachers and Students. By George F. Bosworth. Pp. vi + 197; with maps. (London: Macmillan and Co., Ltd., 1902.) Price 1*s.* 6*d.*

THIS little book deals in a brief manner with the chief facts in the physical and political geography of the countries of the world. Numerous clear maps will enable the beginner to find many of the places mentioned in the text without the aid of a separate atlas. There is scarcely enough information about the many subjects included in the book to make the geography lesson interesting to children, but as a summary the book may be useful

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Note on the Discovery of the Human Trypanosome.

WE have recently seen in the medical Press several very inaccurate accounts regarding the authorship of the important new discovery of trypanosomes in human blood, and of the disease caused by them. For instance, the *Journal of Tropical Medicine* for November 1 (in giving an anonymous description, supported by an editorial, of a case just observed by Drs. Daniels and Manson) attributes the original discovery to Dr. R. M. Forde. It does not mention even the name of Dr. J. Everett Dutton. Dr. Dutton is an old student and assistant in this Laboratory, and is now away on the West African Coast; and we are of opinion that he has a claim to be considered in the matter of this discovery. Another periodical, *The Hospital* for November 8, while also omitting Dr. Dutton's name, states that the discovery was made "within the last few days" by the London School of Tropical Medicine. We believe that such statements are calculated to distort the history of the discovery, and should therefore like to have an opportunity for correcting them promptly in your pages.

The facts regarding the history of the discovery—which was made nearly a year ago—have already been publicly and adequately stated both by Dr. Forde[1] and by Dr. Dutton.[2] Dr. Forde, Colonial Surgeon, British Gambia, tells us that the case in which the parasites were first observed came under his notice in May, 1901; that he found in the blood "small worm-like, extremely active bodies, which I prematurely pronounced a species of filaria," although this conclusion "became doubtful after repeated observations of the parasite"; and that he showed the case in December, 1901, to Dr. J. Everett Dutton, then upon a mission of the Liverpool School of Tropical Medicine to the Gambia, and that Dr. Dutton "at once recognised" the parasite "as a species of Trypanosoma." Dr. Dutton's two papers corroborate these statements of Dr. Forde. After the recognition of the new organism, Dr. Forde gave the first records of the case to Dr Dutton. Dr. Dutton it was, as Dr. Forde says, who recognised that the fever was of a peculiar undulant type; Dr. Dutton it was who positively excluded malaria as the cause of the symptoms; it was he who saw that those symptoms roughly resemble those of tsetse-fly disease and surra; it is he who has published accurate and able descriptions, drawings and charts of the parasites and of the case; and it is he who is now, with Dr. Todd, investigating the subject in West Africa for the Liverpool School of Tropical Medicine.

Dr. Forde is undoubtedly deserving of great credit for his part in the matter, and we think his name should be associated with the discovery. But, until Dr. Dutton was called in, he published no account of the case and did not recognise the nature of the parasite, or the peculiarity of the symptoms. In order to make a discovery, it is not sufficient merely to see an object; it is necessary also to recognise the nature of the object seen and to publish accurate and adequate descriptions of it. For example, Virchow and others long ago saw the parasites of malaria without recognising their parasitic nature; but it is to Laveran, who did recognise their nature, that science gives the credit for the discovery of them. It is certain that Dr. Dutton was the first clearly to observe and to signal the existence of trypanosomes in human blood, and the first to give accurate descriptions of the new organism; and it is to him that science will give the principal credit for the new observation.

It seems to us particularly unfortunate that the *Journal of Tropical Medicine* should have so ostentatiously omitted the name of Dr. Dutton at the moment when it was engaged in giving great prominence to a case of Drs. Manson and Daniels, which, after all, would probably have escaped notice but for the previous work of Dutton. We may mention also—and this is another point which the *Journal of Tropical Medicine* appears to have forgotten—that before his departure for Africa, Dr. Dutton gave at this Laboratory a detailed demonstration, both of the parasite and the clinical features of the case, to Drs. Manson and Daniels, and to one of the editors of the periodical referred to. The omission, then, appears to be due rather to want of memory than to want of knowledge. The journal also states that while the first case (namely, that of Dutton and Forde) was regarded only as a "curiosity," the "discovery of a second case" (namely, that of Daniels and Manson) "opens up a new field for investigation and elucidation," and so on. This view of the relative importance of an original discovery and of a mere confirmation of that discovery is somewhat novel. But the case of Drs. Manson and Daniels is not the second case at all. The second case—also discovered by Dr. Dutton—was that of a child in British Gambia.

It is unnecessary, after what has been said, to deal with the statement made in *The Hospital*. It affords, however, an instance of the curiously rapid manner in which such errors are often propagated in the Press.

We should note that Barron and Nepveu have also claimed to have found flagellates in human blood; but, as will be seen from their writings, their descriptions are so inadequate as to fail to convince us of the accuracy or even the nature of their observations.

The Secular Bending of a Marble Slab under its own Weight.

JUST east of the old brick church in the Rock Creek Cemetery near the Soldiers' Home in Washington is a phenomenon which, so far as I know, is unique. A marble slab, originally plane and resting on four posts at the corners, in the course of about half a century has gradually bent under its own weight and a section of it assumed the figure of a catenary. Careful measurement shows the slab to be 2 inches thick, 35 inches wide and 70 inches long; the posts supporting the slab are 7·5 by 6·75 inches in horizontal section, and so placed that the inner edges (which now furnish the support) are 52 inches apart. The stone has bent so much that the ends of the slab are tipped up one inch above the outer edges of the posts on which they formerly rested. At a distance of 12 inches from the ends, the bending is 1·25 inches; at a distance of 24 inches, the bending is 2·50 inches; and at the centre (distant 35 inches from either end), the bending is 3·05 inches. The stone is a little rough from the effects of atmospheric decomposition, and, of course, the hundredth of an inch is hardly to be depended upon in these measures.

Inquiry as to the epoch of erecting the stone did not lead to definite information, but the inscription gave a date of 1853, thus indicating that it has probably been in position approximately half a century. The superintendent of the grounds has been there some twenty years, and he assured us that the bending of the stone had become much more decided in recent years.

The slab is composed of white marble, of about the texture of the material used by sculptors, and appears sufficiently crystalline and homogeneous to take a polish. On the under surface, the stretching of the material has given rise to a number of small cracks, such as develop in plaster where it bends. The chief interest in the phenomenon arises from the evidence it furnishes that *marble is in reality a fluid of enormous viscosity*. This has, of course, some bearing on the question of the rigidity of the rocks composing the crust of the earth and the gradual adjustment of the earth's figure under gravity.

Washington, D.C., November 3.

November Swallows.

SINCE the end of October I had not seen a single swallow. This afternoon, however, between four and five o'clock, I saw a party of six, or more, leisurely hawking over the trees and house-tops. It was occasional appearances such as this, after the general exodus, which led Gilbert White to believe that swallows did not all migrate. On seeing some on November 4, near Newhaven, he writes:—

"I am more and more induced to believe that many of the

swallow kind do not depart from this island, but lay themselves up in holes and caverns; and do, insect-like and bat-like, come forth at mild times and then retire to their *latebrae*."

So far as I can make out, November 7 is the latest date on which White records having seen swallows. In 1900 I observed them here throughout the month of November—usually not more than from one to three at a time—up to November 30. In 1901 I never saw one after the end of October.

Recent study of migration seems to show that those individuals of a species which breed farthest north are the last to migrate south. But it is hard to believe that these November swallows are those which have bred in the most northern region visited by the species, say, Iceland and the Faroes. How could they have subsisted in those more boreal climes while ours, "foggy, raw and dull," forced them to flee across the seas? I venture to suggest that they are individuals which had already accomplished a part of their southward retreat. They had reached, perhaps, the south of France or Spain. It would be a small matter for such powerful fliers to pop back for a brief interval, tempted by a spell of mild weather. And there is reason to believe that in retiring to their winter quarters many species perform the journey in a much more leisurely fashion than when they make their great rush to their breeding grounds.

G. W. BULMAN.

13 Vicarage Drive, Eastbourne, November 12.

THE MYCENÆAN DISCOVERIES IN CRETE.

FOR several years past the attention of archæologists has been directed more and more to Crete. The reasons for this access of interest in the antiquities of the great Mediterranean island have already been explained in the two articles on the "Older Civilisation of Greece," which appeared in NATURE, vol. lxiv. p. 11, and vol. lxvi. p. 390. In Crete, revelations of the older culture of the Greek lands are now being made at a very rapid rate, and it is to Mr. Arthur Evans that the palm for these revelations must be awarded. Through many years of greater or less success he has explored the byways of Crete, convinced that the great island would eventually yield results of the greatest importance for the elucidation of the early history of Mediterranean civilisation, and now he has had his reward in the remarkable discoveries which have attended the systematic excavations which he has at last been able to carry out on the site of the ancient Knossos, the city of Minos himself. It is the excavation of Knossos which has directed public attention to the possibilities of Cretan exploration, and there is no doubt that in importance this excavation ranks far higher than any other in Crete. This being so, it is with Knossos that we may fitly commence our survey of these Cretan explorations. Enough has been said in the two articles previously mentioned to give the reader a general idea of the discoveries at Knossos, and of the peculiar characteristics of the earlier Mycenæan age in Crete—which we ought, perhaps, rather to designate, with Mr. Evans, the "Minoan" age—which have been revealed by these discoveries.

Knossos lies about four miles south of the town of Candia, or Herákleion, as the Greeks call it. The walk thither is pleasant; the road (a rarity in Crete) resembles any English country lane. In front rises the curious isolated cone of Iuktas, the fabled burial-place of Zeus, which seems steadily to increase in size as we proceed southwards, and at Knossos dominates the surrounding country. Breasting a hill, Iuktas comes into fuller view; on either hand are rolling downs, backed by mountains; further on, a couple of roadside wine-shops, a house, and a path off to the left across the fields to a white patch with a wooden summer-house in the middle of it, from the top of which floats the Union Jack; this is Knossos, where Minos judged, where Theseus slew the Minotaur.

Coming from the west, one enters first the great western court, which, if one is not a timid Dryasdust, but an archæologist who takes pleasure in repeopling the ground on which he stands with those heroic figures which are associated with it in legend, one may call the Dancing-floor of Ariadne if one will. Crossing to the south-west corner, one reaches the remains of a great gate at this end of the beautiful wall of polished gypsum blocks which separates the court from the rest of the palace, and so round through the corridors which once were adorned with frescoes of tribute-bearers coming in procession, into the long north-and-south gallery out of which open to the left the curious long cupboard-rooms or "magazines" in which were stored the great earthenware *pithoi*, with ornament in relief, containing tablets or other objects of value, which are so characteristic of Minoan palaces. Most of these remain *in situ*, some broken or overturned by falls of masonry, many roughly restored with plaster to keep them together. In the floors open the curious lead-lined safes or receptacles for valuables, called "Kasellais" by the diggers, made with the greatest care in double tiers, and still almost excavator-proof. Unluckily, most of the golden treasures which they once contained seem to have been removed before the final catastrophe which overwhelmed the palace of Minos. Over one of these magazines stands the "summer-house" already mentioned, which is really a kind of gazebo, built by Mr. Evans for the purpose of obtaining a panoramic view of the excavations. Hence we pass round to the right, to the throne-room, which opens on to the central court. This is now roofed over, in order to protect its contents from the weather, and the curious brightly-coloured modern Mycenæan pillars, tapering from capital to base, which occupy the site of the ancient columns, with the red-painted walls, give us an interesting idea of what the place once looked like. It should be remembered that there is no "restoration" here; it is purely a work of conservation; the form and colour of the modern pillars are supplied from a Knossian fresco, the colour of the modern walls is but a continuation of the colouring of the ancient. The effect is good. Leaving the throne-room of Minos, with its curious throne with back in the form of an oak-leaf and legs carved with Gothic crockets, its stone seats for the councillors, its bath and its great stone bowl, we cross the central court eastwards to the edge of the hill, and then descend part of the wonderful quadruple staircase, which was excavated by Mr. Evans with so much difficulty and is now held in place by wooden arches, to the "Hall of the Colonnades," in which one might fancy oneself in the court of an Italian palace. Above us is an open loggia, which can be attained from half-way up the stairs. The existing palace is just here nearly three stories high, and was originally four or more! As Mr. Evans points out (*Journal of Hellenic Studies*, xxi. p. 335), "even at Pompeii staircases one over the other have not been brought to light." Passing out, we reach the "Hall of the Double-Axes," so called from its pillars and wall-blocks, which are engraved with the mystic sign of the god of Knossos and of Diktê, who was afterwards (?) identified with the Aryan Zeus. Everybody knows the brilliant philological explanation by Mayer and Kretschmer which has made clear the meaning of *Λαβύρινθος* as "Place of the Double-Axe," and so has converted the guess that the Knossian palace is the Labyrinth itself into a practical certainty.[1] One

[1] In the *Journal of Hellenic Studies*, xxi. part ii. p. 268, Mr. W. H. D. Rouse complains of my having followed Mr. Evans in accepting this explanation of the word "*Λαβύρινθος*" and having adopted his identification of the Knossian palace with the Labyrinth in my book "The Oldest Civilization of Greece." Mr. Rouse does not accept the explanation, and so will not adopt the identification. I apprehend, however, that his refusal to accept the explanation of the name is due to the fact that he is hardly cognisant of all the arguments for it. For instance, he says that the termination *-νθος* is not explained! (*loc. cit.* p. 274). He will find it fully explained in

may believe in the existence of the Labyrinth without believing in the existence of an actual Minotaur!

Leaving the Hall of the Double-Axes, we bear round to the left above the little valley of the Kairatos to the ancient northern entrance, where is to be seen a very interesting surface-drain which carried off water from the central court. And now we again stand outside the palace with our faces turned in the direction of Candia.

Looking back, we are at once struck by a feature of Knossos which entirely differentiates it from Tiryns or Mycenæ. It is not fortified. "Bastions" there may be at the northern entrance, but they do not seem to have been of any particular military value. The Labyrinth was not a fortress, it was a peace-time palace, the residence of kings who ruled a settled people and needed not to fear armed attack. But one day war came to Knossos, and the dominion of the proud Minoan thalassocrats disappeared in the smoke of the burning Labyrinth.

This open and unfortified character of the palace testifies to the high state of civilisation of the Minoan Knossians, thus agreeing with all tradition of the great Cretan law-giver who personifies the ancient princes of Knossos. But high civilisation often brings degeneracy in its train, and, as has already been pointed out in these columns (vol. lxvi. p. 393), there are many traits in the culture of Knossos which give the modern observer a decidedly sinister impression.

Of the Mycenæan town of Knossos, excavated by Mr. Hogarth in 1900, which lay to the south-west of the palace, there is not much to be seen. A discovery of Mr. Evans's, made during the present season (1902) and communicated by him to the *Times*, may, however, give us some idea of what the town may have looked like. To quote Mr. Evans:—"This is the remains of a mosaic, consisting of small porcelain plaques, which in its original form seems to have represented scenes disposed in various zones recalling the subjects of Achilles' shield—the walls and houses of a city, a river, a vine and other trees, warriors with bows, spears, and throwing sticks, besiegers and defenders, and various animals. But the most surprising part of all are the houses of which the city is composed. Fragmentary as are their remains, it has been possible to reconstitute about a couple of score of these. The varying character of the structure—stone, timber, and plastered rubble—is accurately reproduced; and the walls, towers, gateways—a whole street of a Minoan city rises before us much as it originally stood. But what is even more surprising than the fact that the elevations of these prehistoric structures should be thus recovered for us intact from the gulfs of time is the altogether modern character of some of their features. Here are three-storeyed houses (some of the semi-detached class showing two contiguous doorways) with windows of four panes, or double windows of three panes each, which seem to show that the inmates of the houses had actually some substitute for glass." Perhaps they had window-glass; why not? It was known to the Romans, and has been found at Pompeii. However this may be, it would indeed seem, as Mr. Evans says, "as if the brilliant and unexpected character of the finds" at Knossos is "likely to maintain itself to the last."

the chapters of Kretschmer's *Einleitung* on the languages of Asia Minor and the pre-Hellenic population of Greece (x., xi., p. 289 *ff.*; *esp.* p. 404). I should also like to refer him to my article in NATURE November 14, 1901, Suppl. p. vii, where he will find the matter explained to the best of my ability. With regard to another point which has been urged against the correctness of the identification of the Knossian palace with the Labyrinth as being, *par excellence*, the "Place of the Double-Axe," I confess that I do not see that the fact of the Double-Axe sign being cut upon the rough stone blocks of the walls, which were intended to be covered with stucco or with gypsum slabs, is of much weight, as I am inclined to regard these signs as hieroglyphs, intended merely for the guidance of the masons, signifying that such and such a block was intended for a building or room somehow connected with the worship of the god of the Double-Axe. Indeed, the hieroglyphic of their tutelary deity may have been used by the Minoans as a sort of heraldic device to mark "Government stores," exactly like the British "broad arrow." I do not know whether this explanation will commend itself to Mr. Rouse or not, but it appears natural enough to a student of Egyptology.

We retrace our steps to Candia and thence start for Phaistos, on horse- or mule-back. We pass Knossos once more, we pass Iuktas, and so on over the watershed between the Ægean and Libyan seas, with snowy Psiloriti (Ida) on the right hand and Lasíthi (Diktê) on the left, into the Messará, the valley of the Ieropotamos, to the acropolis-hill of Gortyna, which stands at the entrance of a remarkable gorge through which flows the Lethaios of the ancients. The site of this once famous city, which supplanted both Knossos and Phaistos as the chief town of Crete, was investigated by the Italians two or three years ago, and again examined by Mr. Taramelli in 1901; he found no traces of occupation in Mycenæan days. Hence we pass down the broad Messará to the triple acropolis of Phaistos at Agia Photiá, first identified by Admiral Spratt.

Phaistos stands upon a triple-peaked hill, which forms the end of the spur which divides the Messará from the maritime plain of Dhibáki, where the Ieropotamos reaches the sea. At its base runs the Ieropotamos. Its situation is therefore much stronger than that of Knossos, and seems to be better adapted for a fortress than the low knoll on which the Minoan metropolis stood. On the third, the lowest, peak, Prof. Halbherr and the Italian expedition have excavated a Mycenæan palace, the architecture of which is entirely Knossian—Minoan—in type; we find here the same corridors, the same magazines, the same pillared halls and open courts as at Knossos. There is no doubt whatever that the palaces of Knossos and Phaistos were built by the same people and approximately at the same period. Legend ascribes the foundation of Phaistos to Minos, and there is no reason to doubt that this legend enshrines forgotten history. If, then, Phaistos was founded by the Knossians, its palace would be expected to show signs of a somewhat later date than Knossos. These signs are quite apparent. Phaistos marks a development of, an improvement on, Knossos. In some ways it must have been much finer; certainly its ruins are much more impressive. The masonry at Knossos is neither so good nor so well preserved as that at Phaistos; the curious triangular θεάτρον at Phaistos, with its altar and tiers of stone seats, has no parallel in the mother-palace, nor has the latter now anything to compare with the great and broad stairway which leads up to the pillared hall at Phaistos, although it is possible that some similar stairway may once have existed at Knossos, but has now disappeared. Phaistos, then, makes a finer show than Knossos, but is really far less interesting. In the first place, it has no legendary past to speak of; we know nothing of its ancient dynasts, while Knossos was the city of Minos, the metropolis of the ancient dominion over land and sea which is connected with the name of the great legendary lawgiver, and its palace is in all probability the identical Labyrinth which the legendary Dædalus built for the great king. In the second place, Phaistos is nothing but bare walls, fine though their masonry may be, and has yielded practically none of those minor discoveries which tell us so much more than bare walls can; while Knossos, on the other hand, has, as we know, yielded minor discoveries of the utmost importance, which have revealed to us most of our present knowledge of Minoan civilisation and have told us its date.

One difference between Knossos and Phaistos, however, is noticeable, and that a somewhat significant one. Phaistos was more strongly fortified than Knossos, and in many places the palace walls, built of ponderous stones like Mycenæ and Tiryns, are visible. This we should expect in a building which was evidently placed where it is for more or less military reasons, and it confirms the idea that Phaistos was built by the Minoan rulers of Knossos with the direct purpose of controlling

the mouth of the Ieropotamos and the more southerly haven of Mátala, and so securing the communications of Knossos with the southern sea. Originally founded by the Knossian princes Phaistos probably was not; such a site must always have been occupied from the earliest days of human settlement in the Messará, and, as a matter of fact, primitive pottery of days long anterior to the Mycenæan period has been found at Phaistos, and in the near neighbourhood is Agios Onouphrios, where one of the most important discoveries in Crete, that of burials of the primitive pre-Mycenæan or "Amorgian" period, containing Egyptian scarabs of the twelfth dynasty (*c.* 2200 B.C.), was made in 1887. But its foundation as an important city Phaistos no doubt owed to the conquering rulers of Knossos, and to them the construction of its fortified palace is most probably due.

This season is announced the discovery at Agia Triadha, between Phaistos and the sea, of what is described as a "country residence" of the Phæstian princes, which will no doubt prove of very great interest. Indeed, it appears that a large number of Mycenæan seals, an inscribed tablet of the Knossian type, and other objects of interest, including a portion of a stone vase sculptured with a most realistic representation in relief of a body of men leaping and dancing in a religious procession (apparently a harvest-home, judging from the implements carried by the dancers), have already been found here. The neighbourhood of Phaistos is rich in remains of the older civilisation of Greece. Northwards, at the end of a valley of Ida, lies the cave of Kamárais, where was found the store of that peculiar pottery which has proved to be characteristic of the period of Cretan art which immediately precedes the true "Mycenæan," the period to which the earliest foundation of the palaces both of Knossos and of Phaistos must be assigned, the period, probably, of the earliest Minoan kings. A large store of this ware was discovered by Mr. Hogarth in the town of Knossos, and it has also been found at Phaistos, Zakro and other Minoan sites. Further, and this is most interesting, it was also found by Prof. Petrie at Kahun, in Egypt, and may there be roughly dated to the period between the twelfth and eighteenth dynasties, not earlier than the twelfth, but no doubt earlier than the eighteenth. It was, then, imported into Egypt from Crete between 2000 and 1700 B.C. Here is another piece of evidence as to date which fits in absolutely with the evidence of the alabastron-lid of Khyan and the statuette of Àbnub, found at Knossos.[1] Everything points to *c.* 2000–1500 B.C. as the date to be assigned to the early Minoan period.

The other well-known cave on Mount Ida, the "Idæan Cave" *par excellence*, explored by Messrs. Halbherr and Orsi, contained objects, mostly of post-Mycenæan and early classical date, exhibiting strong traces of Phœnician influence. It lies further north, above the Nida plain.

To the south-east, in the direction of Gortyna, stood once a Mycenæan city on the curious isolated hill of Kourtais, the necropolis of which has yielded interesting Late-Mycenæan and Geometrical finds. Another explored site which may be mentioned is Priniá, to the north; away to the east, in the province of Pediada, where the Omphalian Plain meets the lofty mountains of Lasithi, the ancient Diktê, and the as yet unexplored site of Lyttos awaits the excavator's spade, the necropolis of Erganos has yielded the interesting tombs of a Mycenæan hill-settlement, and the district of Embaros innumerable traces of extensive occupation in Mycenæan times, both early and late. This country must in Minoan days have formed part of the immediate territory of Knossos; the town of Lykastos, which lay within it, was said to have been founded by Minos, and Lyttos is associated with the legends of the Cretan Zeus, who was supposed to have passed his childhood in a cave on the slopes of Diktê. This cave has been identified, and Mr. Hogarth has explored it. It is a "large double cavern situated to south-west of, and about 500 feet higher than Psychro, a village of the upland Lasithi plain," a curious tract which lies in the middle of and surrounded by the Dictæan mountains. Mr. Hogarth's discoveries in the Dictæan Cave have already been noticed in NATURE (vol. lxiv. p. 15); it need only be said here that he has shown that it was probably one of the holiest places of Crete, and the hundreds of Mycenæan votive double-axes which he found are final proof of the identity of the prehistoric God of the Double-Axe with the Cretan Zeus, which again shows the identity of the Cretan with the Karian Zeus, whose emblem was the λάβρυς or Double-Axe and the seat of whose worship was Labraunda, which confirms the equation Λαβραυ-νδα = Λαβυρι-νθος, explains Λαβύρινθος as the "Place of the Double-Axe," and so identifies the Knossian palace as the Labyrinth of Minos. Most interesting is the discovery in the Dictæan Cave of a bronze figure of the Egyptian God Amen-Rā, Amonrasonter, "the King of the Gods," probably dating to about the eleventh or tenth centuries B.C., which was perhaps dedicated by some Egyptian traveller who identified the God of the Double-Axe with his own supreme deity, thus anticipating the later conjunction Zeus-Ammon by many hundred years! From this cave came the well-known inscribed libation-table, now in the Ashmolean Museum. It was no doubt from Diktê that the Cretan mountain-goddess Diktynna, also called Britomartis, took her name, and not from the Greek δίκτυον, "a net."[1]

South-west of Diktê is a district in which many Mycenæan sites still await the spade, as at Rotási (Rhytion) and Viano (Biennos); on the south coast is Arvi, where, a few years ago, an important find of early Mycenæan stone vases was made, and where an ancient cult of Zeus probably points to a direct connection with Knossos.

Rounding the northern slopes of Diktê, we enter the province of Mirabello, where, at Milato on the north coast, an important Mycenæan tomb has been found, and where, further south, the imposing ruins of Goulàs, the ancient Lato, investigated by Messrs. Evans and Myres and afterwards partly excavated by a French explorer, M. de Margne, without much success, no doubt mark the site of a Minoan city and palace. The place-name Minoa preserved in classical days the tradition of Knossian domination hereabouts also. We have now reached another depression in the mountain-system of Crete, the hilly plain which lies between the Gulf of Mirabello and the district of Hierapytna on the south coast. Before us to the east rises another mountain-mass, which stretches from sea to sea and seems to block all further progress eastward. This is the Aphendi Vouno of Kavousi, which bars off from the rest of Crete the extreme eastern portion of the island, the modern province of Sitía, of old the territory of the Eteokretans, who were said to be first cousins of the non-Aryan Lycians, and certainly still spoke an absolutely non-Greek idiom even in classical times. In the Eteokretan country itself we find little proof of Minoan occupation except here and there on the coast, so it is probable that direct Knossian control in Minoan times ended with the Hierapytnian territory. The most easterly Minoan town in this district appears to be that discovered in 1901 by Miss Harriet Boyd at Gournia, on the Gulf of Mirabello, at the foot of the Aphendi, and nearly opposite the island of Psyra. In the same neighbourhood, at Kavousi, Miss Boyd had made fruitful excavations in the preceding year, but her discoveries at Gournia far

[1] See NATURE, vol. lxvi. p. 392. The identification of the Kahun ware with that of Kamárais is due to Mr. J. L. Myres.

[1] See "The Oldest Civilization of Greece," p. 296, where I have explained the form of the name.

exceed these in interest, and are of such great importance that the following short description of them, taken from the *American Journal of Archaeology* for January–March of this year, p. 71, is here quoted:—"A Mycenæan acropolis was found, approached by two long streets, about 5 feet wide, with terra-cotta gutters and good stone pavements. These lead to the palace of the Prince. Right and left are side streets and houses. The steeper parts of the roads are built in steps. The houses have rubble foundations, but the upper walls are of brick. In some parts of the palace the upper walls are of ashlar. Several houses have walls standing to the height of 6 or 8 feet. Plaster is used extensively for the facing of walls and door jambs. There are many proofs of the existence of a second story. Twelve houses have been excavated, most of which have eight rooms or more. Of the palace, fourteen rooms have been excavated, chiefly magazines, like those at Cnossus. A terrace court, a column base, and an aula, evidently belonging to a portal, have been uncovered. In the centre of the town is a shrine. It is a small, rectangular building, near the top of the hill. The most noteworthy of its contents are a low terra-cotta table, with three legs, which possibly served as an altar; cultus vases with symbols of Mycenæan worship; the disk, 'consecrated horns of the altar' [see NATURE, November 14, 1901, Suppl. p. vii.], and the double-headed Axe; and a terra-cotta idol of the 'Glaucopis Athene' type, with snakes as attributes . . ." The smaller objects found are of the usual Mycenæan type, including stone and bronze utensils. Very significant is the fact that the Double-Axe is found painted on vases, and carved also on one of the stone blocks of the palace, as at Knossos and at Phaistos. This marks the place as Minoan at once. Very possibly it was the frontier-town of the Knossian dominion on the Eteokretan border. It is "the most perfect example yet discovered of a small Mycenæan town." In fact, a Minoan Pompeii on a small scale!

Beyond the Aphendi Kavousi we are in the province of Sitia. On the site of the ancient Eteokretan capital, Praisos, excavations have been carried on by Prof. Halbherr and by Mr. R. C. Bosanquet, the present director of the British School at Athens. Here a few remains of Mycenæan culture were found by Mr. Bosanquet, including a large "beehive" tomb. Another inscription in the non-Hellenic tongue of the Eteokretans[1] was discovered, of course, of a date long posterior to the Mycenæan period!

Mr. Bosanquet has also excavated at Petras, a place on the harbour of Sitia, and, during the present year, at Palaiokastro, on the east coast, south of Cape Sidero, where he has found some very curious Mycenæan interments. Palaiokastro is, I am informed by Mr. Bosanquet, bigger and more important, as a site, than Gournia and Zakro, but more disturbed by cultivation. As a Mycenæan settlement, it is quite as noticeable as Zakro; a remarkable characteristic is the occurrence, dotted all over the plain, of the foundations of Mycenæan farmsteads, on which Mr. Bosanquet lays stress, as a fresh proof of the peaceful security enjoyed by the Mycenæan Cretans. Further south again, at Zakro (which Spratt considered to be the site of Itanos, but probably erroneously, since Erimopoli, north of Palaiokastro, has a better claim to this honour), Mr. Hogarth has discovered the remains of an important Mycenæan port-town, which, he thinks, was a Minoan outpost, a Knossian colony planted here to hold the most important haven on the east coast, which is still used by the sponge-fishers, who make it their rendezvous before starting for the African coast. Mr. Hogarth's discoveries here have been more fully referred to in the last volume of NATURE, p. 394, *q.v.*

We thus see that the main result of the excavations on Mycenæan sites in Crete which have been going on for the past two or three years has been the proof of the existence in the great Mediterranean island of a civilisation which was already ancient and highly developed at least as early as 1700 B.C., and was in connection with Egypt at that date and probably earlier. The origin of this culture is at present veiled from us; but various strange indications of a primeval connection with Egypt seem to point to *Africa* for its origin. More than this cannot be conjectured at present. Its centre seems to have been the central portion of Crete, the territory of Knossos and Phaistos, which is inextricably bound up with the famous legends of Minos and the Knossian thalassocracy. Mr. Evans's discoveries have breathed life into these legends, and though we may not believe in Minos as a historical personage, at any rate we see that he represents a dynasty and a power, and so we can speak of the Minoan dominion in Crete and of the Mycenæan civilisation of Crete, the chief monuments of which are at Knossos and Phaistos, as "Minoan."

The Knossian dominion extended in the east apparently as far as the borders of the independent Eteokretan country. One or two Knossian colonies seem to have been established on its further coast, such as Palaiokastro and Zakro. Similar Minoan colonies seem to have been also established in other islands of the Ægean, as in Melos, at Phylakopí. That we have here a confirmation of the legend of the Minoan thalassocracy there can be little doubt.

How far the Knossian dominion extended westward is as yet unknown. Axos, which lies at the upper end of the Mylopotamo valley at no great distance from the Knossian district, is now being excavated, but has as yet yielded nothing Mycenæan. There can, however, be little doubt that it was a Minoan city. I have elsewhere[1] suggested that the *Uashasha*, who invaded Egypt in concert with other Mediterranean tribes in the reign of Rameses III., probably some three hundred years after the most flourishing period of the Minoan age, were Cretans from Axos, and have given my reasons for the suggested identification. The objection that Axos is an inland town and so would not have taken part in an over-sea expedition is of no weight whatever; like Knossos, Lyttos, or Gortyna, each of which cities possessed a dependant port on the coast, Axos no doubt possessed its coast-haven, either in the neighbourhood of Bali Bay or nearer the mouth of the Mylopotamo. Further, Axos is actually connected in legend with Libya, and Herodotos (iv. 154) mentions traditions which connect it, as well as Itanos, with the Theræan colonisation of Cyrene. Other central and western sites, such as Eleutherna, Hyrtakina, Phalasarna, &c., will no doubt yield Mycenæan remains when excavated. In fact, the whole of Crete seems to be covered with traces of Mycenæan culture; I have not mentioned numbers of unexcavated sites from which inscribed seal-stones, &c., have been obtained.

The Minoan culture was probably older than the Mycenæan civilisation of continental Greece, and there seems little doubt that the original inspiration of the latter was derived from it.

Eventually the highly civilised and apparently peaceful Minoan dominion in Crete, weakened, perhaps, by luxury and unused to war, was overthrown by foreign attack. Who the conquerors were we do not know, but they probably came from the north. We may, perhaps, associate with their attack the convulsions among the

[1] I must here state that in "The Oldest Civilization of Greece," p. 87, I had not the remotest intention of attributing to Mr. Arthur Evans the opinion that the well-known Inscription of Praisos was inscribed in a Semitic idiom. I was fully aware that he held no such view. I merely referred to his "Cretan Pictographs" as the latest authority on the subject generally. Unluckily, the small number pointing to the note below, containing this reference, was misplaced in the text. It was printed after the word "Eteokretans," but should have come after "Praisos," four lines above. I regret that this escaped my notice when reading the proofs of my book, and still more that the nature of the mistake was not understood.

[1] "Oldest Civilization of Greece," p. 177.

Mediterranean tribes which caused the piratical onslaughts on Egypt in the thirteenth and twelfth centuries B.C., in which Cretan wanderers, expelled from their island by the northern newcomers, may well have taken part. It is certain that before this time the highly civilised Minoan Cretans or *Keftiu* had disappeared from the ken of the Egyptians, and are no more seen in Egyptian wall-paintings. One result of this convulsion seems to have been the settlement of a Cretan tribe, the Philistines, on the coast of Palestine.

When Crete emerges from the dark age which followed the break-up of the Minoan power, we find it a congeries of Greek city-states of the usual type, but of a more quarrelsome disposition than elsewhere; in the Minoan land itself, Gortyna conquers and destroys Knossos and Phaistos, in the east Hierapytna wages long wars with Praisos and Itanos, and so forth. Crete takes no part in the colonising activity of the new Greece, and is henceforth of no account in Hellas. Her day of glory had passed away with the Heroic age.

I am indebted to Mr. R. C. Bosanquet for information with regard to the work of the British School at Athens in eastern Crete. Subscriptions for this work will be gladly received by Mr. Walter Leaf, 6 Sussex Place, Regent's Park, N.W.

H. R. HALL.

P.S.—Photographs of the remains at Hyrtakina have been published by Messrs. Savignoni and De Sanctis in their publication "Esplorazione Archeologica delle Provincie Occidentali di Creta" (Rome, 1901). From their publication it would appear that Phalasarna, the most westerly site in the island, was certainly of Mycenæan origin. Near the remains of a city is a colossal stone throne, of the same type as those treated of by the late Dr. Reichel in his "Vorhellenische Götterkulte," on which is a relief of a symbolic pillar (see Evans, "Mycenæan Tree and Pillar-Cults," in the *Journal of Hellenic Studies*, vol. xxi. p. 99 *ff.*; reviewed in NATURE, November 14, 1901, Suppl.). The name Phalasarna is of the now easily recognisable "kleinasiatisch" præ-Hellenic type. Kretschmer has pointed out that the last two syllables may well be the same as the name of the Bœotian Arnê, which he has identified with the Lycian word *arñna*, "city" ("Einleitung in die Geschichte der griechischen Sprache," p. 406). There seem to be Mycenæan traces also at Vlithiàs and at Agia Irene (Kantanos?); see Savignoni and De Sanctis, *loc. cit.*, for photographs of polygonal masonry, &c.

Mr. Bosanquet informs me that he has found Mycenæan pottery-fragments on the small island of Mókhlos (wrongly called Hagios Nikólaos in Kiepert's map of 1897), off the north coast between Kavousi and Sitia.

THE SECOND INSTALMENT OF THE BEN NEVIS OBSERVATIONS.[1]

THE forty-second volume of the *Transactions* of the Royal Society of Edinburgh is devoted to the publication of five years' observations at the Ben Nevis Observatories, in continuation of those included in vol. xxxiv. of the same series of *Transactions* published in 1890, with appendices consisting of discussions of the results. It is edited by Dr. Buchan, the meteorological secretary to the directors of the observatories, and Mr. R. T. Omond, honorary superintendent of the observatories. The cost of printing is borne by the Royal Societies of London and Edinburgh. The observations include hourly readings and summaries of the meteorological elements, together with entries in the log-book at the summit station for the five years 1888-1892, and readings, five times daily, at the public school, Fort William, from January, 1888, to December, 1890; also the hourly readings with various summaries for the Fort William Observatory from the establishment of that institution in the autumn of 1900. There have also been added tables of mean hourly values of the barometer, temperature, &c., at Ben Nevis and Fort William Observatories, computed to the end of 1896, with mean monthly temperatures deduced from independent observations in the Stevenson screen at Fort William for the period August 1, 1890, to December 31, 1896, and differences between the observations in the Stevenson screen and the thermograph screen of the Observatory. It is almost needless to say that the publication of these tables will be welcomed as representing the primary results of an enormous amount of patient and painstaking labour, controlled by a representative board of directors of conspicuous distinction and carried out by a body of enthusiastic observers in circumstances of no little difficulty.

This is not a suitable occasion for dealing independently with the observations, which are presented with the skill and care of which Dr. Buchan is an acknowledged master, and with all the assistance an accomplished printer can afford. We naturally turn to the appendices as representing the scientific results which have been obtained by those who have been associated with the working of the observatories and have devoted time and study to the many problems which the observations suggest.

The appendices consist of a series of papers, some of them *in extenso* and appearing now for the first time, others in abstract or reproduced from the publications of the Royal Society of Edinburgh or the Scottish Meteorological Society by Dr. Buchan, Mr. Aitken, Mr. Buchanan, Mr. Omond, Mr. Mossman and Mr. Rankin.

A brief survey of these discussions is sufficient to show that the problems suggested by the meteorology of Ben Nevis, taken separately or in comparison with that of Fort William, are many and difficult. Dr. Buchan returns to a voluminous but still unexhausted subject in a paper on the diurnal range of the barometer in fine and cloudy weather at stations in various latitudes, from San José, Costa Rica, to Jan Mayen in the North Atlantic. Mr. Aitken's report on atmospheric dust and Mr. Buchanan's discussion of the meteorology of a station in the clouds, as represented by the Ben Nevis records in foggy weather, are already well known contributions to science. The other papers are, as a rule, of less general scope.

Much attention is devoted to the relation of barometric readings at the summit to those at the base station, and here one of the difficulties of Ben Nevis observations becomes very conspicuous. When the velocity of wind reaches or exceeds twenty miles per hour, the barometer reading at the summit no longer represents the pressure of the air within 0·01 inch. All barometric readings with anything more than a moderate wind are subject to a correction of uncertain amount on account of dynamical disturbance. Moreover, the shape of the mountain, with its great cliff on one side of the summit, has a very marked effect upon the wind measures. This circumstance reminds me of a personal experience at Dover during a gale, when the only place in Dover screened from the wind was the top walk of the Admiralty pier, apparently as fully exposed to the gale as any position could be. Such dynamical effects upon barometer and wind make it very difficult to bring the summit observations of these primary meteorological factors into relation with corresponding observations elsewhere.

These are not the only difficulties associated with the reduction of the summit barometer readings to sea level, and the account of the attempts to carry out this reduction

[1] "The Meteorology of the Ben Nevis Observatories." Part ii., containing the Observations for the Years 1888, 1889, 1890, 1891 and 1892, with Appendices. Edited by Alexander Buchan, LL.D., F.R.S., and Robert Trail Omond.

suggests the possibility of regarding the barometric difference between Fort William and the summit as a primary element, without introducing a correction factor based upon a system really applicable only in the case of small heights. Differences from mean value instead of differences from a common hypothetical datum would probably give a more effective representation of the conditions.

The Ben Nevis work, as represented in this volume, is essentially self-contained. In the course of the discussion, observations at other stations are sometimes employed, but the work of other meteorologists concerned with similar problems is hardly referred to. Clayton and Fredlander are the only names I have noticed in the volume not immediately associated with Ben Nevis. This may possibly be accounted for by the majestic isolation of the Ben, but it is in some respects unfortunate. For example, a system is adopted for adjusting the twenty-four-hourly readings for non-periodic changes which is different from that adopted by the Meteorological Council in an annual publication dealing with their first-class observatories, including Fort William. If I judge rightly, one of the two systems must be wrong, and if the error is in Victoria Street it would have been wiser to point out the fact in adopting a different system. Again, a table of equivalents of the numbers of the Beaufort scale and wind velocities is given (pp. 5 and 492), in which numbers on the Beaufort scale are represented by velocities largely exceeding, indeed nearly double, those quoted by Hann ("Meteorologie," p. 377). The practice with regard to the use of velocity equivalents of the Beaufort scale is in a sufficiently chaotic condition already, and it is to be feared that the addition of another scale of equivalents without reference to the reasons for disregarding all other attempts to reduce chaos to order must tend to make confusion a little worse confounded.

The publication of the observations down to 1892, or in part to 1896, may seem to the reader a little belated. The editors are, however, to be warmly congratulated upon the substantial progress made with the work undertaken by the directors. The publication is opportune for two reasons. First, because the question of the future of the observatories is prominently before the public and the volume gives an adequate representation of their work. Secondly, because the International Meteorological Committee meets at Southport next September during the session of the British Association, and the occasion would be a suitable one for the discussion of the interesting questions arising out of observations at high levels. It is justly claimed for Ben Nevis as a high-level station that it is in an unique position. The first recorded entry in the log-book (January 1, 1888) is that the tracks of a hare were seen near the thermometer box. It is not the only hare to be raised on the Ben. If opportunity can be found for the discussion of some of the Ben Nevis hares at Southport, our visitors will relish their highland flavour.

W. N. SHAW.

NOTES.

THE following is a list of those to whom the Royal Society has this year awarded medals. The awards of the Royal medals have received His Majesty the King's approval:—The Copley medal to Lord Lister, in recognition of the value of his physiological and pathological researches in regard to their influence on the modern practice of surgery. The Rumford medal to the Hon. Charles Algernon Parsons, for his success in the application of the steam turbine to industrial purposes, and for its recent extension to navigation. A Royal medal to Prof. Horace Lamb, for his investigations in mathematical physics. A Royal medal to Prof. Edward Albert Schäfer, for his researches into the functions and minute structure of the central nervous system, especially with regard to the motor and sensory functions of the cortex of the brain. The Davy medal to Prof. Svante August Arrhenius, for the application of the theory of dissociation to the explanation of chemical change. The Darwin medal to Mr. Francis Galton, for his numerous contributions to the exact study of heredity and variation contained in "Hereditary Genius," "Natural Inheritance" and other writings. The Buchanan medal to Dr. Sydney A. Monckton Copeman, for his experimental investigations into the bacteriology and comparative pathology of vaccination. The Hughes medal to Prof. Joseph John Thomson, for his numerous contributions to electric science, especially in reference to the phenomena of electric discharge in gases.

MEN of science do not need to be reminded that their interests are cosmopolitan. Contributions to natural knowledge are not weighed in political balances, but by a scale of worth independent of nationality. Every effort should therefore be made to give clear evidence of this unity of spirit and bond of intention. An opportunity of doing this is afforded by the meeting of the American Association for the Advancement of Science, to be held in Washington, D.C., from December 29 of this year to January 3, 1903. At the recent Belfast meeting of the British Association, Prof. C. S. Minot, the president of the sister association across the Atlantic, gave a sincere and hearty invitation to the members of our Association to attend the forthcoming meeting at Washington. There are doubtless many men of science who would accept the invitation with the keenest pleasure if they could leave their work for the few weeks required for a visit to the United States; and if they are unable to do so the loss and regret will be theirs. To those who are able to make the journey, it ought to be regarded as almost a duty—though a pleasurable one—to attend the meeting. The mid-winter meeting is an experiment on the part of the American Association, but it has attracted a large number of affiliated societies, and there is every promise that the meeting will be an important one. Since Prof. Minot gave the cordial invitation at Belfast, a letter has been received from the permanent secretary of the American Association, Dr. L. O. Howard, expressing the hope that at least some of the officers and members of the British Association will be present at the Washington meeting. It will be to the advantage of both science and civilisation if this friendly invitation is accepted.

ANOTHER meeting which men of science who have a few months' holiday at the end of next year should attend is that of the Australasian Association, to be held in Dunedin, New Zealand, in January, 1904. Mr. G. M. Thomson, honorary secretary, has sent a letter to the general secretaries of our Association asking them to make known to members that special opportunities will be given to see the most interesting sights in New Zealand, so that the visit may be made a source of profit as well as of pleasure. Dunedin is the most southerly city of any importance in the British Empire, and it is scarcely necessary to remark that many lands and peoples of interest can be seen by men of science who are able to take a trip around the world to New Zealand. A formal invitation to attend the meeting will be brought before the members of the British Association next year at Southport.

DR. P. L. SCLATER, F.R.S., has resigned the secretaryship of the Zoological Society of London, and only holds office until his successor is appointed. The council has passed the following resolution on this subject and ordered it to be entered on their minutes:—"The president, vice-presidents and council of the Zoological Society of London desire to

record their sincere regret at the retirement of their secretary, Dr. Philip Lutley Sclater, after a service of nearly forty-three years. They wish to tender him their hearty thanks for his most valuable services to the Society during this long period, not only in the management of the Zoological Gardens, but also in the conduct of the publications of the Society and the general direction of its affairs. These affairs have prospered to a remarkable degree during his long term of office. The income of the Society has doubled, the Society's library has been entirely created, the membership has increased from 1500 to 3200. Dr. Sclater's own work as a zoologist is held in universal repute, and it is no exaggeration to say that the very high position occupied at the present day by the Zoological Society in the world of science is largely due to the exertions and the personal character of its retiring secretary."

IN the *St. James's Gazette* of November 17, "C. S." discusses the question as to the kind of winter we are to have, basing his arguments on a statement made by Bacon three centuries ago, that "a moist and cool summer portends a hard winter," and on the fact that severe winters have certainly occasionally followed wet or cool summers during the last century. The years particularly instanced are 1878, 1879 and 1880, which were followed by severe winters. The last severe winter was that of 1894–5, following a rather bad summer. The past summer bears considerable resemblance to that of 1879. We have occasionally referred to this subject, our remarks being chiefly based on Dr. v. Hellmann's discussion of the long series of Berlin observations. The results arrived at by Dr. Hellmann in a paper laid before the Berlin Academy in March, 1885, do not clearly support the views of "C. S.," so far as Berlin is concerned. Dr. Hellmann found that after a moderately warm summer a mild winter was probable, and, on the contrary, that a cold winter followed a warm summer.

OWING to illness, Mr. James Swinburne, president of the Institution of Electrical Engineers, was unable to be present at the opening meeting of the new session of the Institution, held on Thursday last. His inaugural address was therefore postponed. It was announced that Prof. Ayrton had, from ill-health and pressure of other business, resigned the honorary treasurership of the Institution, and that Mr. Robert Hammond had consented to fill his place. The council has had under consideration the continuance of the useful and pleasant visits of the members of the Institution to foreign countries, and has arranged the preliminaries for a visit to Italy in the spring of next year. The Institution has received a cordial invitation from the American Institute of Electrical Engineers to visit the United States and hold a joint meeting there or in Canada. The communication suggested that such a meeting might be arranged for Montreal next year, or at some spot in the eastern part of the United States in 1904, to include a subsequent visit to the St. Louis Exhibition, where an electrical congress will be held. The council has decided that as a meeting for next year could not be arranged, owing to the projected visit to Italy, the invitation for 1904 should be accepted. It was suggested at the same time that the joint meeting might be held in Canada, where the Institution might hope to receive the cooperation of the McGill University.

A REUTER message states that the *Morning*, which has been sent out as a relief ship to the *Discovery*, has arrived a Lyttelton, New Zealand.

PROF. J. WILLARD GIBBS, professor of mathematical physicst at Yale University, New Haven, has been elected a corresponding member of the Academy of Sciences at Munich.

A MEMORIAL tablet in memory of Richard Jefferies was unveiled at Swindon on Saturday by Lord Avebury. The tablet has been erected at the house where Jefferies lived for two years before his death.

PROF. J. MILLAR THOMSON, president of the Institute of Chemistry, and Miss Thomson, have issued invitations to a private soirée to be held at the Galleries of the Royal Society of British Artists on Wednesday, December 10.

THE Paris correspondent of the *Chemist and Druggist* states that the Paris Academy of Sciences has awarded the Lavoisier medal this year to Prof. Cannizzaro, of Rome, in recognition of his contributions to the advancement of chemistry.

THE new building of the Museum of Egyptian Antiquities at Cairo was opened by the Khedive on November 15 in the presence of Lord Cromer and Lord Kitchener, the Ministers, the Sirdar, and many European and native officials. The whole collection has been arranged in the new building under the supervision of the director, M. Maspero, and the curator, Emil Brugsch Bey.

A FEW particulars of the eruption of the Soufrière of St. Vincent which occurred on October 15 and 16 are given in extracts from despatches received by the Colonial Office. Sir R. B. Llewelyn, the Governor of the Windward Islands, remarks that there has been a largely increased area of land damaged by this last outburst, and the prospects are now much blacker than they were. It is suggested as a matter for serious consideration whether Georgetown, at present deserted, may not have to be abandoned; indeed, it is considered doubtful whether any part of the island can confidently be said to be without the range of danger from the volcano, and the possibility of abandoning the whole island has therefore to be faced.

REPORTS from Samoa published in the *Times* state that the volcano on the Island of Savaii is in active eruption. Several craters are emitting dust and vapour, and one village is two inches deep in ashes. Reports from Honolulu, dated November 11, state that, according to a wireless message from Hawaii, the volcano of Kilauea in that island has been in a state of the most violent eruption known for the last twenty years. A Reuter message from Catania states that a fresh eruption of Stromboli took place on November 16, and that incandescent stones, smoke and dust were thrown out. There was an explosion, followed by other silent eruptions, and a flow of lava. A shock of earthquake, accompanied by a loud rumbling noise and lasting five or six seconds, occurred at Oran, Algeria, on November 17, about 9.30 p.m.

AT Seville Cathedral on November 17, the ceremony of depositing the ashes of Christopher Columbus in a special mausoleum was carried out with impressive solemnity. The remains of Columbus rested for two centuries at Santo Domingo, and in 1796 were transferred to the Cathedral at Havana. After the Spanish-American war, they were taken to Spain, where, by desire of a descendant of Columbus, the Duke of Veragua, they have been interred in Seville Cathedral.

A REUTER message from Mantes, France, states that the navigable balloon constructed by the brothers Lebaudy made its first free ascent on November 3. Several ascents were made, the balloon returning to a given spot each time. It moved in all directions above the fields and woods which border the Seine. The report states that in every instance the airship was brought back to its starting-point at a speed of 25 miles an hour, the turn being made against the wind.

LARGELY with the idea of broadening the demand for German wares, Germany will take part in the Universal Exposition to be held in St. Louis in 1904. This decision has now

been officially announced. It is as yet unknown what sum of money is likely to be set aside for the purpose of the St. Louis exhibit, but from assurances given by the Emperor that every branch of German artistic, manufacturing, agricultural and industrial developments will be represented, it is supposed that 200,000*l.* will be devoted to the objects of the exhibit.

A MEETING of the executive committee of the Cancer Research Fund, under the direction of the Royal Colleges of Physicians and Surgeons, was held last week. Dr. Bashford, who has been appointed to the post of superintendent of cancer research, has decided to proceed at once to Germany to inquire into the present lines of investigation in that country, and to cooperate, as far as possible, with the German committee, especially in the direction of statistical investigation. The statistical committee which has been appointed will at once enter into correspondence with scientific workers in the United States, and Prof. Gilman, principal of the Carnegie Fund in Washington, has already expressed his willingness, through the chairman of the executive committee, to take joint action with the British committee, both in regard to statistical and laboratory investigation.

THE death of Mr. William H. Barlow, F.R.S., at the age of ninety, is announced in the *Times*. He was a distinguished civil engineer, well known as the designer of the St. Pancras Station and other large works upon the Midland Railway, to which he was consulting engineer. He was the son of Peter Barlow, F.R.S., who was professor of mathematics at the Royal Military Academy, Woolwich. Mr. Barlow inherited much of his father's mathematical ability, and his chief claim to recognition is that in the early days of railway engineering he endeavoured to introduce more scientific precision into the design of engineering structures. He was the inventor of a form of rail intended to dispense with the use of cross-sleepers. Jointly with Sir John Hawkshaw, he was engineer for the Clifton Suspension Bridge over the Avon. Mr. Barlow was the engineer of the new bridge over the Tay, built to replace the structure blown down in December, 1879, and was one of the committee of selection appointed to consider the designs for the new Forth Bridge.

THE Society of Arts commenced its 149th session on November 19 with a meeting at which an address was delivered by Sir William H. Preece, the chairman of the council, and the medals awarded by the Society during the past session were presented. At the next meeting, on November 26, Dr. Goegg will read a paper in French on the Simplon Tunnel and its effects on railway traffic to the East. At the other meetings before Christmas, there are to be papers on "Photographic Development," by Mr. Watkins; on "French Education," by Mr. C. Brereton; and on the "Russian Iron Industry," by Mr. Head. There will also be a meeting of the Indian Section, at which a paper on "Domestic Life in Persia" will be read by Miss Ella Sykes, who, with her brother, Major Molesworth Sykes, has had much experience of Persian travel. The Monday evenings up to Christmas will be devoted to a course of Cantor lectures on "Gas and Allied Illuminants," by Prof. Vivian Lewes.

WE learn from the *Times* that a meeting of the Stonehenge Committee, consisting of Lord Dillon, the Bishop of Bristol, Mr. Thackeray Turner, Mr. John Carruthers, the Rev. E. H. Goddard, Mr. N. Story Maskelyne, Mr. W. Gowland and Mr. C. H. Read, representing the Society of Antiquaries of London, the Wilts Archæological Society and the Society for the Protection of Ancient Buildings, was held at Burlington House this week. The committee received a report of the operations that had taken place under its advice, with the sanction and at the cost of Sir Edmund Antrobus, expressed approval of the steps already taken towards ensuring the safety of Stonehenge, and repeated its resolve that further steps must be guided by the determination to do as little as possible in order to save the monument for posterity. The committee is anxiously conscious of the fact that in the present state of Stonehenge there is grave danger of further accident. To meet the dangers of the present winter, it has now recommended the immediate application of wooden props to the stones about which the chief anxiety is felt.

UNDER the title *The Foreigner in Italy*, a new weekly paper has been started under the auspices of a new organisation founded last spring and styled the "National Association favouring the Foreign Element in Italy," 11 Piazza Barberini, Rome. The first number, bearing the date November 1, contains a notice of the ships which have been submerged in the lake of Nemi since the time of the Romans, and which it is proposed to raise by artificially draining the lake for the purpose. These ships, which were of the nature of floating palaces, have been examined on one or two occasions (1535, 1827, 1895), and explored by means of diving bells. One is 64 metres long and 20m. broad, and slopes down from 5m. to 12m. in depth at a distance of 20m. from the shore: the second is 71m. long, 21·4m. broad, and its depth is from 16m. to 22m., its distance from the shore being 50m. and from the first 200m. Further particulars have been given in numbers which have since appeared. The second number contains a short note upon the legendary origin of the name Pelée. The original Pelée is said by tradition to have been a maiden who was pursued by a giant and fled to the crater of the volcano for refuge. The gods of the volcano came to her assistance and overwhelmed the giant with lava, burying him beneath the rocks.

AN account of the mathematical work of Ernest de Jonquières is given in the *Bibliotheca mathematica*, iii. 3, by Prof. Gino Loria, of Genoa, who has also contributed a list of his papers and notes to the mathematical *Bolletino di bibliografia*, published by Clausen, of Turin. Jean Philippe Ernest Fauque de Jonquières was born at Carpentras on July 3, 1820, and died on August 12, 1901. His earliest recorded notes bear the date 1855, but from 1860 onwards he devoted himself for some time to the line of study opened up by Poncelet and Chasles, and in 1862 he was awarded two-thirds of the prize offered in connection with the study of curves of the fourth order. His mathematical writings, of which, including solutions to questions, 155 are enumerated, deal mainly with the following points: the higher geometry of Chasles, the theory of algebraic plane curves and systems, properties of algebraic gauche curves and surfaces, geometrical transformations and Eulerian polyhedra, theory of equations and theory of numbers.

IN the *Bulletin* of the Tokio Mathematico-Physical Society, Mr. T. Hayashi discusses the so-called "isosceles trapezium problem," according to which, if an ellipse be inscribed in an isosceles trapezium and circles are inscribed in the four corners, each circle touching the ellipse and two sides of the trapezium, then the radii of the four circles form a proportion. This problem has previously received attention from Japanese mathematicians. It looks as if a proof ought to be possible based on the property that tangents to an ellipse are proportional to the parallel diameters. Incidentally, it is proved that the points of contact of the inscribed ellipse divide the parallel sides proportionally; this is a simple corollary of the anharmonic property of four tangents.

REFERRING to a recent fatal accident caused by the unfortunate opening of one of the carriage doors of a train in motion, Sir Oliver Lodge, F.R.S., gives some sensible advice to passengers

in a recent letter to the *Times*. He points out that the door on the left of the traveller with his face towards the engine, with its hinge forward, is safe; but the door on the right, with latch forward, is very unsafe to open even slightly. The wind rushing by at hurricane speed gets into the opening, snatches the door wide open, thereby pulling the unwary passenger with his hand on the latch out on the line. If the door is six feet by three and the wind is exerting an average pressure of twenty pounds to the square foot, the force on the open door is as much as three cwts.

A RECENT issue of the *Scientific American* contains a description of the multiplex system of page-printing telegraphy described by the late Prof. H. A. Rowland. In this system, alternating currents are used for transmitting the signals, which are made up by suppressing different combinations of two half-waves in a series of eleven half-waves. The transmitting instrument has a typewriter keyboard, and four operators work over the same line; the messages sent by the different operators are separated by a commutator, which rotates in a quarter of a second and allows each operator to use the line for one-quarter of this period. In this way, with duplexing, 1920 signals or 320 words can be sent over one line in a minute. The receiving instrument prints the message on a sheet of paper, spacing it out into words and lines so that it appears like an ordinary typewritten sheet. It is said that the system has been successfully operated under the Government in America over a distance of 550 miles.

THE paper on "Electric Tramways" read by Messrs. C. and B. Hopkinson and E. Talbot before the Institution of Civil Engineers last week derives especial interest from the fact that it is based on the experience gained by the authors in the construction of the tramways at Leeds and Newcastle-on-Tyne. The chief points considered were the generation and transmission of power, the construction of rolling stock, and the vexed question of earth returns and electrolysis. It is interesting to note that the authors find that with seventy or more cars the load is so nearly constant that the steam consumption per unit is practically the same as for a constant load. In such a case, therefore, batteries are only needed as a stand-by or for night work. As regards electrolysis, it is stated that experiments showed that, except in special circumstances, the 7-volt Board of Trade limit might be exceeded many times without risk of damage to gas and water pipes, but if high conductivity strata existed at certain parts, there might be considerable damage caused by the leakage currents even below the 7-volt limit.

THE Report for the year ended December 31, 1900, of the Meteorological Service of Canada, compiled by the director, Mr. R. F. Stupart, has now reached us. The report consists of an introduction in which the Canadian observing stations are classified and the weather conditions summarised for each month of 1900. This is followed by separate parts, containing monthly and annual summaries for the chief stations; meteorological summaries for telegraph reporting stations; bi-hourly and hourly temperatures and barometric pressure during 1900; mean, maximum and minimum temperatures; rainfall and snowfall in 1900; and amount of bright sunshine registered in each month.

A STRIKING instance of the value of the work performed by meteorological observatories to those engaged in agriculture is contained in the last report of the chief of the U.S. Weather Bureau. On the morning of February 23, 1901, the following special warning was telegraphed from Washington to Jacksonville, Florida, with instructions to give it the widest possible distribution throughout the State. "Temperature will fall to-night to a minimum of between 20° and 25° at Jacksonville, and to freezing as far south as Tampa, with frost extending somewhat south of the latitude of Jupiter." Frost occurred as predicted, and the minimum temperature at Tampa was 32°. More than 500 telegrams were sent from the Weather Bureau office at Jacksonville, and the railroads of the State energetically cooperated in disseminating the warnings. Fruit and vegetable growers estimated the value of orange bloom, vegetables and strawberries known to have been saved, as a result of the warnings, at more than a hundred thousand dollars.

IN part iv. of vol. lxxii. of the *Zeitschrift für wissenschaftliche Zoologie*, Herr K. Hesse brings to a conclusion his valuable account of recent researches on the visual organs of invertebrates.

THE latest issue of Gegenbaur's *Morphologisches Jahrbuch* (vol. xxx. part iv.) contains a "symposium" on the morphology of the cloaca and certain of the reproductive organs of the amniote vertebrates.

IN the *Emu* for October, Mr. A. W. Milligan gives an illustration and description of the nesting-mound of one of the megapodes, the mallee (*Lipoa ocellata*). It appears that in hot weather the birds remove the top of the heap so as to form a saucer-like depression, which is again filled up when the weather becomes rainy. The author was fortunate enough to see the cock-bird performing the latter operation. A feature of this number of the *Emu* is the beautiful plate of the eggs and nest of the chestnut backed quail.

THE evidence as to the origin of the paired limbs of vertebrates forms the subject of an article by Prof. B. Dean in the October number of the *American Naturalist*. This evidence, it is urged, is strongly in favour of the view that paired limbs have been developed from skin-folds running along the sides of the body, as exemplified in the earliest and most primitive sharks. In the same issue, Prof. D. S. Jordan discusses the coloration of fishes, and concludes that, as in other vertebrates, some colour-types in this group serve for protection, others act as recognition-marks, while others, again, have been developed for sexual attraction.

WE have received the prospectus, together with an advance copy of the preface, of the long-expected work on the mammals of Egypt commenced by the late Dr. John Anderson and completed by Mr. W. E. de Winton, which promises to be of the highest value to naturalists. For many years before his death, Dr. Anderson had been assiduously collecting Egyptian mammals; but, even with the assistance of others, the series of specimens available to the authors, although very large, was not in all respects complete. Mrs. Anderson, who made all arrangements for the publication of the work and has supervised its contents, has herself contributed the preface. The price of the work, which is uniform with Dr. Anderson's "Reptiles of Egypt," has been fixed at seven guineas net.

THE *Illustrirte Zeitung* of September 18 contains a good figure of the aye-aye of Madagascar, taken from a specimen living in the Zoological Garden of Berlin. It is, however, quite incorrect when Dr. Heck, who writes the accompanying letterpress, claims that this is the only figure of this animal ever drawn from life. Prof. Owen's celebrated memoir on *Chiromys madagascariensis*, published in the fifth volume of our Zoological Society's *Transactions* in 1862, contains an excellent figure of this animal, taken from the specimen living in the Regent's Park Gardens in October, 1862, and drawn by the celebrated artist Joseph Wolf. There have been at various times *four* examples of the aye-aye living in the Zoological Society's Gardens, and its anatomy and osteology were elaborately described from them

by Owen forty years ago. Now our friends at Berlin are congratulating themselves because they have obtained a single individual, and are trying to make out that the animal has never been properly figured !

AMONGST the recent additions to the Zoological Society's reptile house are several specimens (deposited by the Hon. Walter Rothschild, M.P.) of the very curious large iguanoid lizard (*Conolophus subcristatus*) which inhabits the central islands of the Galapagos group, and the habits of which were described by Darwin in his "Naturalist's Voyage" (vol. iii. p. 469). It is a terrestrial species, and is stated by Darwin to be so numerous in certain districts that he and his companions could scarcely find a spot free from their burrows on which to pitch their tent. Closely allied to it is a large marine species of lizard (*Amblyrhynchus cristatus*), also confined to the Galapagos group, which lives exclusively on the rocky sea-beaches and is said "to go out to sea in shoals to fish." Living examples of the latter species were also brought away by Mr. Beck, Mr. Rothschild's collector, from the Galapagos, but, unfortunately, they did not reach England alive.

WE have received parts xii. and xiii. of the *Bulletin* of the Geological Commission of Finland, containing papers on the crystalline rocks of the country by B. Frosterus, and on a meteorite by W. Ramsay and L. H. Borgström.

THE *Transactions* of the Leicester Literary and Philosophical Society (vol. vii. part i., July, 1902) contain useful geological maps by Mr. Fox Strangways, on the scale of two inches to a mile, illustrating excursions made to parts of the Soar and Wreak valleys; and there is an instructive infra-Triassic map of Charnwood Forest by Prof. W. W. Watts. There is also a detailed report, with map, on the geology of the Beaumont Leys Estate, near Leicester, by Mr. Montagu Browne. Geology evidently flourishes in this Society under the enthusiastic leadership of Mr. H. A. Roechling.

FROM the New Mexico College of Agriculture and Mechanic Arts we have received *Bulletins* Nos. 42 and 43, in which Mr. J. D. Tinsley deals with the problem of alkali in the soil, and with drainage and flooding for its removal. Sodium carbonate is the essential constituent of "black alkali," as it appears to blacken the vegetable matter in the soil; while other salts of soda, as well as salts of magnesia and lime, help to form what is termed "white alkali" soil. It is pointed out by the author that the alkali is left in the soil by the evaporation of water that has gradually risen to the surface. When this excess of water is removed, the alkali will cease to accumulate and soon be washed out of the soil.

THE latest issue (1900–1901) of the *Proceedings* of the Royal Physical Society of Edinburgh contains a full report of the presidential address delivered by Mr. B. N. Peach in November, 1900, the subject of which is Scottish palæontology during the last twenty years. Full justice is done to workers in all branches of this science, while special attention is directed to the important service rendered by palæontological investigations to the task of unravelling the geological sequence in the Highlands. "The work done in Scotland during the period under consideration has thoroughly established the paramount value of palæontology in the interpretation of the geological structure of the country."

DR. G. T. MOODY describes a new "laboratory shaking machine" in the *Chemical News* of November 7. As a shaking machine capable of giving satisfactory results in the laboratory has long been sought by chemists, it is worth while to direct attention to that devised by Dr. Moody.

A SECOND enlarged and revised edition of "Das Wachstum des Menschen," by Dr. Franz Daffner, has been published by Mr. W. Engelmann, Leipzig (London: Williams and Norgate). The volume contains many interesting papers on the rate and character of the development of the different parts of the human body from embryonic stages to maturity.

IN the numbers of the *Journal* of the Society of Arts for October 17, 24, 31 and November 7 are reprinted the four Cantor lectures recently delivered by Dr. R. T. Glazebrook, F.R.S., on "Glass for Optical Purposes." The first lecture deals with the optical purposes for which glass is used and what it is that the glass used has to do. The defects of microscopes and the way in which they are cured or improved, chiefly by means of the use of glass of varying refrangibility and lenses of different curvature, are included in the second lecture; photographic lenses are considered in the third, and lenses for telescopes in the fourth lecture. Students of optics will find in the lectures a wealth of accurate and instructive information upon many points of interest.

SOME very interesting observations relative to the cause and nature of radio-activity have been recently made by Messrs. Rutherford and Soddy, an account of which is given in the September number of the *Philosophical Magazine*. The experiments were carried out with thorium compounds, all of which are radio-active. The authors arrive at the conclusion that the greater part of the radio-activity of thorium is due to a non-thorium type of matter, represented symbolically by ThX, possessing distinct chemical properties. The activity of this new type is not permanent, but undergoes a gradual process of decay, the value falling to one half in about four days. The constant radio-activity of thorium is supposed to be maintained by the continuous production of this new type of matter from the thorium compounds. Its rate of production and the rate of decay of its activity appear to be independent of the physical and chemical conditions of the system. The ThX is capable of exciting radio-activity on surrounding inactive bodies, and about 20 per cent. of the total activity of thorium is due to this action of the ThX. By suitable means, thorium can be freed from both ThX and the excited radio-activity produced by the latter, and then possesses an activity about 25 per cent. of its original value. This latter, the authors believe, is due to a second non-thorium type of matter.

THE additions to the Zoological Society's Gardens during the past week include two Chacma Baboons (*Cynocephalus porcarius*) from South Africa, presented respectively by Mr. C. S. Blundell and Captain P. J. Probyn, D.S.O.; a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Mr. J. H. Kirby; two Prairie Marmots (*Cynomys ludovicianus*) from North America, presented by the Countess de Grey; a White-collared Mangabey (*Cercocebus collaris*), a Rose-ringed Parrakeet (*Palaeornis docilis*) from West Africa, deposited; two Brown Pelicans (*Pelecanus fuscus*) from the West Indies, received in exchange.

OUR ASTRONOMICAL COLUMN.

CHANGE OF FOCUS IN THE LIGHT FROM NOVA PERSEI.—As previously recorded in these columns (July 3), Prof. E. E. Barnard made several determinations, during 1901, of the visual focus of the light from Nova Persei, in order to determine if the presence of the nebula lines in its spectrum produced the difference from stellar focus observed in the case of planetary nebulæ; his observations showed no decided difference of focus.

Observations made on July 14, August 29, September 1 and September 16 of this year produced a like negative result, and

the colour of the Nova was recorded as "a pale bluish white" on each occasion.

However, further observations, made on October 6, 7 and 14, indicate that the Nova has now assumed a bluer colour than hitherto observed, and that the visual focus is now about 0·2 inch greater than that of a star, that is to say, it now corresponds with the visual focus for planetary nebulæ. Prof. Barnard is certain that this change has taken place since August 29 of this year (*Astrophysical Journal*, vol. xvi. No. 3).

NEW MINOR PLANETS.—In No. 3826 of the *Astronomische Nachrichten*, Prof. Max Wolf records yet another batch of seven new minor planets, all of which were discovered, photographically, on October 25.

The planet 1902 K.E., discovered on October 25, has since proved to be identical with (19) Fortuna, the previously published ephemeris of which was incorrect. A new ephemeris is now given.

The minor planets (477) [1901 G.R.] and (478) [1901 G.U.], discovered by Dr. Carnera, have been named Italia and Tergeste respectively.

OBSERVATIONS OF THE AURORA.—A very interesting and valuable series of observations of the Aurora, which have been made at the Yerkes Observatory during the period 1897–1902, are recorded and commented upon by Prof. Barnard in the current number of the *Astrophysical Journal*.

The observations are recorded *in extenso*, and contain full details of the various phenomena attending the displays. Special notice is made of several interesting features, amongst them being the bank of apparent cloud which has a dark, smoky appearance and generally fills the space on the under side of the auroral arch. This cloud generally gives the appearance of being densely opaque, but that this is not the case is shown by the fact that the observations record the bright appearance of Vega as seen through the apparent cloud. The "pulsating clouds," which are generally 5° to 10° in diameter, are recorded as "fading out and quickly brightening again, as if someone were capriciously turning on and off their light." Another striking feature of the subject, which Prof. Barnard believes to be of importance, is the greatly varying altitudes of the summits of different auroræ, and these are carefully noted in the observations. The positions of the summits of various auroræ are generally recorded as being 20° to 25° east of north. A singular appearance—unique in Prof. Barnard's observations of these phenomena—was that of a quarter of an auroral arch on February 15, 1899, no other signs of auroral display being visible at the time.

The Yerkes observations of the grand aurora of September 10, 1898, which was accompanied by decided magnetic effects, describe it as the grandest display observed throughout the whole period, and state that the light in the north was so intense, at times, as to cast a distinct shadow.

As Prof. Barnard remarks, these observations, which cover a period of sun-spot minimum, will doubtless be important in their bearing on the connection between sun-spots and auroræ.

COOPERATION IN OBSERVING STELLAR RADIAL VELOCITIES.—Prof. E. B. Frost, having been struck by the fact that it is not possible to find, amongst published observations, a dozen stars the radial velocities of which have been determined at more than three different observatories, has sent a circular letter to the recognised workers in this field of astronomical physics asking them to join in a cooperative scheme for observing the radial velocities of the stars given in a mutually selected list.

All of the observers to whom the letter was addressed, seven in number, have agreed to the general scheme, and a primary list of about ten stars has been decided upon. Their programme, for the present, includes the making of three determinations of the radial velocity of each star in the list, per annum, by each observer (*Astrophysical Journal*, October.)

THE MARKINGS ON VENUS.—Prof. Percival Lowell, of Boston, has written to the *Astronomische Nachrichten*, No. 3823, suggesting that the spoke-like markings of the planet Venus are not really present on the surface of the planet, but that their appearance is due to an optical effect produced by the eye wandering from the dark indentations which are seen along the terminator, and the smaller spots and streaks, to the centre of the disc. To test this theory, Prof. Lowell has observed a large number of artificial discs, marked without his knowledge, and set up at a distance so as to be, as nearly as possible, under the same observing conditions as the planet.

These experiments tend to prove his theory, but are not sufficiently decisive to place the non-objective existence of these peculiar markings beyond doubt; therefore Prof. Lowell, for the present, only enters a caveat against the acceptation, as a fact, of their real existence.

THE NERNST LAMP.

THE Nernst lamp can now be said to be well upon its way from the experimental to the commercial stage. It has appeared strange to many people that it has taken such a long time before lamps could actually be bought for use, but a critical examination of the lamps now to be had causes one to wonder, not that its development has taken a long time, but that it has been possible to practically develop it at all. Of all artificial methods of illumination it is the most complicated, and its various auxiliary parts are in themselves inventions requiring for their inception no ordinary genius and perseverance. The Nernst lamps now to be had in England are made by the Allgemeine Elektricitäts Gesellschaft of Berlin. The only other manufacturer of Nernst lamps is the Nernst Lamp Company of the United States, which has acquired the rights for that country. The demands of the rest of the world are being supplied by the A.E.G., the agent of whom for the British Colonies, Asia, Africa and South America is the Nernst Electric Light, Limited, of London, which, in the form of an attractive

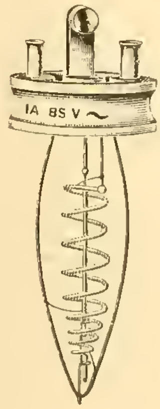

FIG. 1.

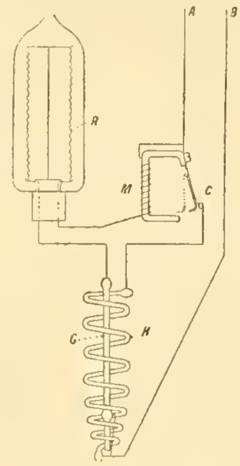

FIG. 2.

pamphlet, has just issued a description of the various lamps it is prepared to sell.

The lamps are of two types and are rated by current, not, as is usual with incandescent lamps, by candle-power, viz. 0·25, 0·5 and 1·0 ampere lamps. The watts consumed per candle-power are about 1·8.

The larger lamp used for all high candle-powers, *i.e.* 50 candle-power and upwards, consists of three parts, the carrier, the lamp body and the globe. The current is led into the lamp body by insulated plug contacts, on the withdrawal of which the lamp is rendered entirely dead and can be handled with safety. The lamp body contains the magnetic cutout for interrupting the current through the heater, after the glower has lighted up, also the series resistance. The contacts for the replacement piece are also carried by the lamp body. This is shown in Fig. 1, and consists of a round piece of porcelain on which are fixed the heater and glower. The general connections of the lamp, as also the functions of its several essential parts, can be seen by reference to Fig. 2. On first switching on current to the lamp, the circuit is closed through the armature and contact C of the cutout M, and through the heater H. The heater is a marvel of ingenuity. It consists of an exceedingly fine platinum wire wound on a rod of porcelain, the rod being in the form of a spiral in the axis of which the glower G is placed. The method of manufacture adopted is to wind the straight rod with the wire, then to cover

this with a protecting layer of porcelain paste and after drying to bend the whole into spiral form by means of a blowpipe. The glower, which is composed of a mixture of zirconium oxide with the yttria-erbia oxides, is, of course, while cold a non-conductor of electricity. Heated, however, by the heater it begins to conduct, rendering itself hotter by its own current energy, getting hotter and hotter until it reaches its normal brilliant state of incandescence. The glower current flowing through the coils of the cutout magnetises the same, causing it to pull in its armature and break the heater current at C.

An unfortunate feature of the Nernst glower is that at the necessary state of incandescence the voltage across it decreases with increase of current. If one wished to express this mathematically, one would say its $\delta v/\delta a$ (v = volts, a = amperes) is negative. A conductor possessing this property placed across supply mains of constant voltage is, however, in an unstable state of equilibrium and will not burn properly. The function of the series resistance R is to correct this. This consists of a very fine iron wire placed inside a glass bulb containing hydrogen gas at low pressure. The thickness of the iron wire is so chosen that at the normal current it is just at its critical stage, *i.e.* at that point, just under the red heat, where its $\delta v/\delta a$ is highly positive; the instability of the glower by itself is thus compensated and the whole glower circuit across the mains is rendered stable.

The smaller lamp, used for all candle-powers below fifty, consists of essentially similar parts to the larger model already described.

As to the economy of the Nernst lamp, the following table shows the result of a test carried out by the Physikalische Technische Reichsanstalt, of Berlin:—

Mean of five lamps. Pressure 220 volts.

Time (hours).	Candle-power.	Watts per candle.
0	35·1	1·65
50	32·4	1·77
100	32·3	1·77
200	30·1	1·85
300	27·5	1·93
400	26·5	1·97
Mean during 400 hours	30·1	1·83

The average life was 380 hours. The heaters were not damaged.

Unfortunately, no information is given as to the source of supply on which these tests were made. Experience already acquired shows that this is of great importance as determining the life of the glowers. Of course, on the basis of 1·8 watts per candle, for a life of 400 hours, the Nernst lamp works out at a saving of about 40 per cent., first cost and renewals included, over ordinary incandescent lamps.

We believe that the lamp is finding, or will find, considerable commercial application, and we anticipate for it a very useful and prosperous future.

C. C. Garrard.

NATURAL PROPORTIONS IN ARCHITECTURE.[1]

It is well known that formal decoration must be based upon exact geometrical construction. The history of art and architecture shows that the most beautiful buildings and formal ornamental *motifs* are those depending upon definite and regular principles. The symmetry of architecture consists of the rhythmical repetition of certain parts of a design in relation to a plan or scheme as a whole, or uniformity as regards the answering of one part to another. The symmetrical forms of Nature have the same interdependence of detail. If a flower is examined which possesses a definite and unmistakable symmetrical adjustment of part to whole, it will furnish a case in point. If even a glimpse could be obtained of the manner in which Nature made the adjustment of her detail, it seemed not unreasonable to expect that the principles involved would be of assistance to design. Even a casual examination showed that much of the harmony of relationship of parts in regular objects could be expressed graphically by geometrical lines. It was found by experiment that this expression was very simple. In most cases, a few circles described concentrically would entirely satisfy zones of symmetry involved in some forms. In addition to the formal plans disclosed in plants, with their leaves, flowers and fruit, the author investigated the beautiful curves of the wings and bodies of butterflies, beetles, moths and bees. He found that in all such examples, these curves were best satisfied by the tangent arcs of circles which had their radii determined by a simple ratio. This ratio almost invariably was a double or binary one, the unit being obtained from the length of the subject's body. With such a unit as a radius, a circle would be described; the diameter of it would be taken as a radius for another, the radius of this for still another, and so on. This progression would be continued until enough arcs had been secured to satisfy all the curves involved. The tangent arcs of circles so related would satisfy these curves, so that it would be impossible for the eye to detect any difference between the approximated and the actual form.

The circles used to satisfy curves of natural objects in this manner may be termed binary circles. They are really circles having radii which form a geometrical progression with a ratio of two. By describing these binary circles concentrically, many proportions involved in the plans of certain forms were accounted for. There were other proportions, however, which these circles did not explain, but the three simple figures which compose the regular polyhedra are involved in the construction

to satisfy them. There are but five possible regular polyhedra, and the three simple figures which compose their faces are the equilateral triangle, the square and the regular pentagon. Once having obtained the primary circles, these simple regular figures may be inscribed in any one of a binary series and a side of each used as a radius to describe others concentrically.

With this simple geometrical formula, it is possible to account for every possible combination of symmetry and proportion. Snow crystals and mineral crystals furnished, so to speak, the converse aspect of the curved forms of organic nature. The straight lines used in the graphic expression of the form of a crystal of any system may be shown to be connected with circles such as have been described. The precision with which this formula analyses the symmetrical shapes of Nature is very remarkable.

If the master architects and decorative artists of the past were guided by Nature, we ought to find an agreement between the proportions of curve and straight line which they employed in their plans and the plans of regular natural objects. This is exactly what a general analysis of architecture and formal art has disclosed. As the designer has used good or bad proportions in his architectural and decorative compositions, there may be found, by this method of analysis and comparison, harmony with the proportions which Nature employs.

The fact that the simple figures of the polyhedra are involved in all symmetrical forms of Nature has naturally suggested that their proportional properties be investigated. If these figures are considered as representing elements of symmetry and the

[1] Abstract of a paper read before the Hellenic Society on November 4 by Mr. Jay Hambidge.

peculiar manner in which they lend themselves to subdivision or multiple expansion is examined, it will be seen that they are inseparably connected with circles which have their radii related in the manner described. Study of these figures will enable one to tell, by merely looking at a proportioned object, the order of its symmetry or character of its plan. For instance, in a cross-section of the young fruit and contained seeds of the verbena, certain circles are involved in relationship to a square. Without making any measurements from the fruit, the plan can be accurately formulated (Fig. 1).

This construction is simple, but it involves principles which are far-reaching. The ground plan of the Parthenon is an instance of architectural construction where the detail is co-ordinated in much the same manner.

The basal projection of the crystal of topaz (Fig. 2) involves all the proportions which occur in regular forms. There are the primary circles the radii of which form the geometrical progression with the binary ratio, and the secondary circles as derived from the sides of the equilateral triangle, the square and the regular pentagon. This example also includes the odd proportion derived from the perpendicular of an equilateral triangle. This

This crystal base contains the entire scheme of proportion and symmetry as found in the Parthenon.

is the only proportion found in symmetrical natural form which seems to be connected with an arithmetical progression.

The Greek and Gothic styles of architecture furnish the most satisfactory results in a comparison of their curves and proportions with the curves and proportions of natural symmetrical forms. In the finest example of the former, the Parthenon, the agreement is so extraordinary that all its proportions and curves may be obtained with no other instrument than a string and a couple of sticks. A surface of levelled earth would furnish a place to make the simple constructions. The beautiful curves found in this building, which so simulate those of conic sections as to deceive the expert mathematician, can be accounted for by this method. In fact, there is no curve in Greek formal art which may not be simply, rapidly and accurately drawn with a compass, and when so drawn, the circles used will be found to possess a definite relationship one to the other. This method would seem to furnish a simple explanation as to how the Greek architects used these curves so long before their supposed discovery. The agreement between the plans of the regular forms of Nature and the plans of the best buildings would seem to suggest that the great architects possessed a formulated or intuitive knowledge of simple principles of proportion which are unknown to us.

[1] ⅃ is the symbol for the perpendicular of the equilateral triangle.

EARTHQUAKES AND EARTH PHYSICS.

PROF. J. MILNE, F.R.S., read a paper on "World-shaking Earthquakes" before the Royal Geographical Society on November 11. In the course of his paper, he remarked that earthquakes may be divided into two groups—first, those which disturbed continental areas, or even the world as a whole, which he called macroseismic, and, secondly, local earthquakes disturbing a few miles' radius, or not more than 100 or 200 miles, which he called microseismic. Evidence of the existence of large earthquakes was sometimes afforded, even though they could not be felt; for example, in 1755, the motion of the water in lakes and ponds observed in England, Scandinavia and North America was attributed to the earthquake at Lisbon. Another form of evidence was sometimes discovered by astronomers, as in May, 1877, M. Nyrén observed disturbances in the level of the axis of the transit at Pulkova, which were held to be due to an earthquake about an hour and a quarter earlier at Iquique. The first instrumental record obtained by the writer of an earthquake which could not be felt was in March, 1884. This and others were referred to as "slow earthquakes." A long series of observations justified him in saying, in 1883, that every large earthquake might be recorded at any point on the land surface of the globe. Thus a new field was open to seismologists, and recording stations were now to be found in many countries, the most complete organisation working in connection with a committee of the British Association. A large earthquake seemed to propagate a series of waves in all directions through and in all directions over the world's surface. Describing in detail the character of this motion, he said that the large waves of earthquakes seemed to pass beneath a country like ours with the character of an ocean swell. The character of these waves was still in process of investigation, and there were reasons for and against any conclusions which might be reached. It would appear that the effective rigidity of the world was about twice that of steel, and it was easy to measure the difference in time between the arrival of preliminary tremors and of large waves—the former reaching a place 80° from their origin in about fifteen minutes, whilst large waves took about fifty minutes. From these differences in times of arrival of different waves, distances of origins could be obtained, and from the distance ascertained from several distant stations the origin might be easily located. Another method of ascertaining origin was the difference of the times of arrival at different stations of large waves, and by these methods the origin of the world-shaking earthquakes for 1899, 1900 and 1901 had been determined. Prof. Milne established a relationship between the distribution of the origins of large earthquakes and the pronounced irregularities of the surface of the earth by a number of illustrations taken from the Alaskan region, which had yielded large seismograms to the Cape of Good Hope, which was antipodean to Alaska, the Cordillerean region, the Antilles, the Andes, Japan, and other parts of the world. He also gave an historic account, dating from 1692, of the mass displacements which had been caused by great earthquakes. As examples, in 1855, in New Zealand, 4600 square miles were raised 1 foot to 9 feet; and in 1897, in Assam, according to Mr. R. D. Oldham, 10,000 square miles of country were displaced possibly 16 feet along a thrust plane.

The connection between large earthquakes and volcanic activity was considered; and instances were given of the seismic convulsions which apparently resulted in reliefs of volcanic strain. So recently as the early part of last summer, the symptoms of volcanic and seismic activities in the Western Hemisphere culminated in the terrible explosions in Martinique and St. Vincent. Prof. Milne also gave the result of inquiries into the relationship between world-shaking earthquakes and unusual movements of magnetic needles. At certain stations, the unfelt waves of large earthquakes disturb magnetic needles, but this is not the case at all stations. This difference in behaviour is not explicable on the assumption that the movements are due to tilting of the instruments, but it is possible that they may be due to magnetic influences. The stations at which movements are observed, Prof. Milne suggests, may be nearer to the magma in which the large waves are propagated than the other stations where movements are not observed. Inasmuch as this magma is not only magnetic, but is also dense at the former stations, the observed value for g would exceed that at the remaining stations, *caeteris paribus*. In support of this view, figures were adduced. References were made to small changes in latitude. When

these were pronounced, world-shaking earthquakes had been frequent. A comparison of the varying number at different periods of small earthquakes showed that the number recorded increased; but this was evidence, not of the growth of seismic activity, but of more general observation. Nearly all large earthquakes were followed by a long series of after-shocks. For example, after the disturbance of October 28, 1901, which had its origin in Central Japan and which might be regarded as a typical world-shaking earthquake, during the first twelve months, 2956 shocks were noted. Next year the number fell to 391. The conclusion seemed to be that in any given year there were 27,500 shocks which could be recorded in epifocal districts, and that, on the average, there annually were 30,000 small earthquakes. From seismograms obtained in epifocal areas, measures of earthquake energy had been obtained. The result was that engineers and builders were now able to build to withstand known forces, and in Japan, in particular, effectual methods had been adopted to resist the severe shakings to which that country was subject. The Japanese Government had so far recognised the importance of seismology as to establish professorships to encourage its study.

THE ROYAL PHILOSOPHICAL SOCIETY OF GLASGOW.

NOT many scientific societies of the kingdom can boast of having existed for a hundred years, but the Royal Society of Edinburgh a few years ago celebrated its centenary, and last week what is now known as the Royal Philosophical Society of Glasgow was engaged in celebrating the attainment of its hundredth year, for it came into being on November 9, 1802, with sixty-two of the most prominent men in the city as members, many of whom have since acquired prosperity and reputation. There was Dr. William Meikleham, the professor of astronomy and natural philosophy in the University, and who was Lord Kelvin's predecessor in the natural philosophy chair, so that those two men practically covered the century between them. There was also Dr. George Birkbeck, subsequently a professor in the "Andersonian," and the founder (in London) of mechanics' institutions. Patrick Cumin, another foundation member, was the professor of Oriental languages. A particularly notable man in the membership was David Mushet, the discoverer of the famous blackband ironstone which did so much to make Scotland the leading element in the creation of the iron industry. Among other original members were Charles Macintosh, who originated the "macintosh" as an article of clothing for wet weather; Mr. John Roberton, a famous iron-founder, who read many papers in subsequent years; and Mr. William Dunn, of Duntocher, a well-known machine-maker. Mr. James Boaz was an accountant; he took a warm interest in the Society, and became secretary in the year 1804, remaining in that office to the great credit of the Society for twenty-six years. Sundry other original members might be named and descanted upon, men from the very highest ranks, and who collectively made Glasgow or contributed very materially towards it, but we must refrain from doing so. Worthy John Geddes, of Verreville, glass manufacturer and potter, was an early member, and he was the second president. The Society did not publish any *Proceedings* or *Transactions* until the year 1844, after Dr. Thomas Thomson, F.R.S., had become president. That gentleman was the famous professor of chemistry in the University, and his knowledge was frequently called forth during the eighteen years that he held the office of president. Mr. Walter Crum, F.R.S., famous as a scientific calico printer, succeeded Dr. Thomson in the chair, and then there was a somewhat continuous run of University presidents, such as Dr. Allen Thomson, F.R.S., Prof. Wm. Thomson, F.R.S. (now Lord Kelvin), Prof. Thomas Anderson (distinguished as a chemist), Prof. W. J. Macquorn Rankine, C.E., F.R.S., and Prof. Henry D. Rogers (American geologist). After he had been knighted, the professor of natural philosophy was again made president for the years 1874-75-76-77. The Society was always in a position to command the services of able and learned men to take the presidential chair, and business men have always been in abundance to fill the executive offices and to discharge the duties pertaining to them for periods extending from six years (in the case of Prof. McKendrick as secretary) to upwards of thirty years, as in the case of Mr. John Mann, the present treasurer.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—An Isaac Newton studentship in physical astronomy and optics, of the value of 200*l*. a year for three years, will be awarded in the Lent term, 1903. Candidates must be Bachelors of Arts who are under twenty-five years of age on January 1, 1903.

IT is announced that a chair of tropical medicine has been founded in University College, Liverpool, with an endowment of 10,000*l*. Major Ronald Ross, C.B., F.R.S., has been elected to the chair.

SIR OLIVER LODGE, F.R.S., was on November 14 entertained at the annual dinner of the Liverpool Philomathic Society, when he delivered an address. He said his removal to Birmingham was solely because of the greater opportunity for his own work which his position in that city afforded him. Speaking of universities, he remarked that the competition among cities to make themselves worthy to become the seat of a university was healthy and holy, and he trusted the movement for establishing a university for Liverpool was gaining ground.

THE second subsection of Clause 18 of the Education Bill, as amended in Committee of the House of Commons on Friday last, lays it down that "the power to provide instruction under the Elementary Education Acts, 1870 to 1900, shall, except where those Acts expressly provide to the contrary, be limited to the provision of instruction given under the regulations of the Board of Education to scholars of not more than fifteen years of age in a public elementary school, but any scholar may remain in such a school to the close of the school year in which he or she reaches the age of fifteen." The difficulty which has existed for some time of defining what constitutes elementary education is thus in a large measure disposed of. An attempt was made to remove the age limit and so allow it to be possible for a child to stay at an elementary school so long as the parents wished. But the intention of the Government appears to be to encourage the drafting of children of capacity into secondary schools, and in this way to reduce expense and also prevent overlapping.

AT the invitation of the University of Cambridge, representatives of all the universities of England and Wales, of the numerous educational associations concerned with secondary education, as well as of the Board of Education, assembled in the Senate House at Cambridge on November 14 and 15 to confer as to the training of teachers in secondary schools for boys. Among men of science who took part in the interesting debates, following the papers on different subjects requiring consideration, were Prof. H. E. Armstrong, F.R.S., Sir Oliver Lodge, F.R.S., Prof. John Perry, F.R.S., and Sir Arthur Rücker, F.R.S. The Vice-Chancellor of the University presided at both meetings, and among the papers, those of Sir Richard Jebb, Mr. Sidgwick and the Master of Marlborough were of particular importance. As Sir John Gorst, whose speech concluded the proceedings, pointed out, if the universities intend to remain at the head of this movement for obtaining suitable training for the masters in secondary schools, they must be progressive and make use of the best of the methods which experience has shown to be suitable to the new demands. One such method, he pointed out, is that by which science is studied by research carried on by the pupils.

SOCIETIES AND ACADEMIES.

LONDON.

Mathematical Society, November 13.—Dr. E. W. Hobson, president, in the chair.—The De Morgan medal for 1902 was presented to Prof. A. G. Greenhill.—Mr. Tucker having retired from the office of secretary, the following resolution was proposed by Dr. Hobson, seconded by Dr. Glaisher, and carried unanimously:—"That the thanks of the London Mathematical Society be offered to Mr. Robert Tucker for the eminent services which he has rendered to the Society during the thirty-five years in which he has held the office of honorary secretary."—The council and officers for the ensuing session were elected. They are as follows:—President, Prof. Lamb; vice-presidents, Mr. Tucker, Dr. Hobson, Dr. Baker; treasurer, Dr. Larmor; secretaries, Prof. Love and Prof. Burnside; other members of

the council, Mr. Campbell, Lieut.-Colonel Cunningham, Dr. Glaisher, Prof. Greenhill, Mr. Macdonald, Major MacMahon, Mr. Western, Mr. Whittaker, Mr. A. Young.—Prof. Lamb having taken the chair, Dr. Hobson delivered an Address on the infinite and the infinitesimal in mathematical analysis. He sketched briefly the history of the attempts that had been made at various times to deal with questions of the infinite, and dwelt especially upon the critical work of the latter half of the nineteenth century, pointing out that pertinent criticism of fundamentals almost invariably gives rise to new construction. He explained how the system of analysis, connected with the title "arithmetisation," had turned a difficulty, to which all previous systems were liable, in that they were unable to give a proof of the existence of the limit. He described the character of the numerical continuum, and contrasted its properties with those of other aggregates, which possess unlimited divisibility. He proceeded to recount the objections that had been raised to the introduction of infinite numbers, as opposed to variables which become indefinitely great; and he concluded with an outline of the theory of transfinite numbers.—The following papers were communicated:—Prof. D. Hilbert, Ueber den Satz von der Gleichheit der Basiswinkel im gleichschenkligen Dreieck. The paper forms part of a critical discussion of geometrical axioms. The possibility of setting up various systems of axioms, so that the axioms of a system shall be mutually consistent and mutually independent, has been proved; and it becomes important to ascertain the relations of the more fundamental geometrical propositions to the possible systems of axioms.—Prof. Burnside, On linear homogeneous groups. The characteristic determinants of any simply transitive, and of any transitive, linear homogeneous group are discussed, and general forms of the determinants are given; the results are applied to simplify the proofs of known propositions concerning the continuous group that is defined by any given group of finite order.—Prof. Lamb, On wave-propagation in two dimensions. The divergence, in two dimensions, of waves from a source, of a more or less transient character, is worked out in detail and illustrated graphically. The disturbance begins suddenly at a place when the wave reaches it; but it does not cease suddenly after a time equal to that during which the source is in action. The existence in two-dimensional wave motion of a sort of "tail" to a wave, which does not occur in the case of waves in one dimension or in three dimensions, is further elucidated by various comparisons between the characters of the three cases.—Prof. A. C. Dixon, (1) Summation of a certain series; (2) Expansions by means of Lamé's functions. The first of these papers is a development of previous work by Morley on the hypergeometric functions that arise from the consideration of the sum of the cubes of binomial coefficients. The second paper contains a discussion of the use of Lamé's functions to determine a potential from its singularities and boundary values for the following regions:—(*a*) the interior of an ellipsoid, (*b*) the exterior of an ellipsoid, (*c*) the space between two confocal ellipsoids, (*d*) two distinct regions, bounded by confocal ellipsoids, wholly or partly coextensive and connected together through the area of the focal ellipse.—Mr. W. H. Young, (1) On sets of intervals, (2) Note on unclosed sets of points defined as the limit of a sequence of closed sets of points. The first of these papers aims at developing the theory of sets of intervals on the straight line in a systematic manner; it is pointed out that, although the discussion of such sets forms a natural introduction to some parts of the theory of aggregates, only a few isolated theorems about such sets have been formulated hitherto. The object of the second paper is to obtain the necessary and sufficient condition that the content of the set obtained by closing an unclosed set, which is the limit of a sequence of closed sets, may be the limit of the contents of the closed sets of the sequence.—Prof. Hill, The continuation of certain fundamental power series. The object of the paper is to illustrate the theory of continuation in simple cases in which the work need not be artificial. The continuations, along arbitrary circuits, of the binomial series, the logarithmic series, the series for arc tan x, are developed in detail. The methods of the paper depend upon theorems proved by Abel in his classical memoir on the binomial series.—Prof. L. Crawford, A geodesic on a spheroid and an associated ellipse. The length of the arc of a geodesic drawn from a given point on a spheroid in a given direction is found as the length of an arc of an ellipse, and the difference of longitude of any point on the geodesic and the given point is expressed as an elliptic function of an angle connected with the corresponding points on the same ellipse; an expression is found for the change in longitude on return along the geodesic to the same latitude.—Prof. A. W. Conway, The propagation of light in a uniaxal crystal. New forms of integrals of the equations of propagation are obtained. The results are applied to the discussion of the direction of vibration and the flow of energy; it appears that the ray direction is not the direction of the energy flux in waves diverging from a source within the crystal. Applications of the integrals are also made to discuss the passage of parallel and of divergent beams of light through a thin crystalline plate.—Mr. E. T. Whittaker, On a new connection of Bessel functions with Legendre functions. A symbolic relation, which connects the functions in the case where the order of the Bessel functions is half an uneven integer, is transformed into an expression for the Bessel functions of unrestricted order as definite integrals involving Legendre functions of unrestricted order.

Chemical Society, November 6.—Prof. McLeod, F.R.S., in the chair.—The following papers were read:—The specific heats of gases, by Mr. H. Crompton. An extension of the application of Le Chatelier's formula for the specific heats of elementary gases to the vapours of complex substances.—The action of nitric acid on bromophenolic compounds, by Mr. W. Robertson. An investigation of the effect produced by displacement of the hydroxyl group by methoxy- or acetoxy-groups in inhibiting the replacement of bromine by nitroxyl.—3:5-dichloro-*o*-xylene and 3:5-dichloro-*o*-phthalic acid, by Drs. Crossley and Le Sueur.—The combination of carbon monoxide with chlorine under the influence of light, by Drs. Dyson and Harden. These gases when dried, mixed in equal quantities and exposed to light, undergo first a period of photochemical induction and finally reach a stage of equilibrium with the carbonyl chloride formed.—The constituents of commercial chrysarobin, by Dr. Jowett and Mr. Potter.—The constituents of oil of rue, by Dr. Power and Mr. Lees. The following new constituents have been obtained:—methyl *n*-heptylcarbinol, methyl *n*-nonylcarbinol, methyl salicylate, cineol, limonene and pinene.—Methyl β-methylhexyl ketone, by Mr. H. Lees.—Diindigotin, by Dr. Moir. This substance was obtained by the application of Baeyer's process for the synthesis of indigotin from *o*-amidocinnamic acid to the diphenyl analogue, benzidine dicarboxylic acid.—The localisation of phosphates in the sugar-cane, by Mr. Sprankling.—On the non-existence of the gaseous sulphide of carbon described by Deninger, by Messrs. Russell and Smith.—Isometric anhydrous sulphates of the form $M''SO_4,R'SO_4$, by Mr. F. R. Mallet.—The catalytic racemisation of amygdalin, by Dr. J. W. Walker. The optically active glucoside is converted by the hydroxyl ions of aqueous alkaline solvents into racemic amygdalinic acid.—On asymmetric optically active selenium compounds, and on the hexavalency of selenium and sulphur, by Prof. Pope and Mr. Neville. Methylphenylselenetine has been obtained in dextro- and lævo-modifications by fractional crystallisation of the *d*-bromcamphorsulphonate.—The transformation of acetylchloroaminobenzenes into the isomeric chloroacetanilides, by Drs. Chattaway and Orton.

PARIS.

Academy of Sciences, November 10.—M. Albert Gaudry in the chair.—On uniform transcendentals defined by the equation $y'' = 6y^2 + x$, by M. Paul Painlevé.—On quasi-waves, by M. P. Duhem. From the theoretical examination of the velocity of propagation of sound waves in air, it is shown that if the coefficient of conductivity has a finite value, however small, the waves will be propagated in accordance with the formula of Newton, and it is only in the case where the conductivity coefficient is rigorously zero that the waves will travel in accordance with the formula of Laplace. But although the conductivity of air is small, it is not zero, and this leads to a serious discrepancy between theory and experiment. The author shows that the existence of viscosity in air, although small, renders impossible the propagation of waves properly so called, and examines the conditions of transmission of the quasi-waves which are possible, and succeeds in showing that an explanation of the discrepancy becomes possible.—Further observations and experiments relating to the determination of the velocity of the X-rays, by M. R. Blondlot. According to the theory put forward by Wiechert and Sir G. G. Stokes, the X-rays consist, not of continuous ether vibrations, but of extremely short, isolated pulsations, and this hypothesis has been shown to give a complete explanation of the absence of refraction and reflection and of the diffraction phenomena shown by the rays. All the experimental results obtained by the author are also in accord

with this hypothesis, which appears to render a complete account of all the facts at present known.—Study of the climate of Toulouse from 1863 to 1900, by M. B. Baillaud.—Remarks by M. Haton de la Goupillière on a recent paper by M. Gréhant on the analysis of air from mines.—On the present condition of the volcano at Mont Pelée, by M. A. Lacroix.—Gravity along the mean parallel, by M. J. Collet.—On Cremonian substitutions in space, by M. Léon Autonne.—On the breaking and displacement of equilibrium, by M. Jouguet.—On the equivalence of differential systems, by M. E. Cartan.—On certain remarkable equalities, by M. W. Stekloff.—On Hall's phenomenon and thermoelectric power, by M. Edmond van Aubel. According to the views of Nernst and von Ettingshausen, there should be a relation between the thermoelectric power and Hall's phenomenon in metals. It was found by Becquerel that certain alloys of bismuth and antimony and a mixture of bismuth with bismuth sulphide possess very high thermoelectric power, and these have now been examined by the author with respect to the magnitude of the Hall effect. The results confirmed the theory of Nernst and von Ettingshausen.—On the conductivity of solutions at low temperatures, by M. J. Kunz. The electric conductivities of solutions of sulphuric acid have been determined at temperatures between 0° C. and −70° C. The conductivity does not vanish at −39°C., as had been suggested by Kohlrausch, but diminishes continuously with the temperature.—Some new experiments on the electrical resistance of selenium and its application to the transmission of luminous images and impressions, by M. Dussaud.—The artificial production of rubies by fusion, by M. A. Verneuil. The exact conditions necessary for the production of artificial rubies have now been worked out, and specimens have been obtained possessing a fine red fluorescence, and which have been found by the lapidaries employed to cut them to possess the same hardness as natural rubies, and to take the same fine polish. Occasionally, rubies have been made which it is impossible to distinguish from natural ones, but as a rule there are slight faults which can be made out on careful examination.—On the alloys of copper and magnesium, by M. O. Boudouard. The fusing points of a series of alloys of copper and magnesium, when arranged on a curve, give three maxima and four minima. The former correspond to the existence of three definite alloys, $CuMg_2$, CuMg and Cu_2Mg. The mechanical properties show a general parallelism with those of the aluminium-copper alloys, studied by Debray.—On the presence of volemite in some Primulaceæ, by MM. J. Bougault and G. Allard. The polyatomic alcohol, extracted from the roots and rhizomes of *Primula grandiflora*, and previously described as primulite, has now been recognised as identical with the volemite of Bourquelot and E. Fischer.—Study of the chemical composition of copal, by M. Marcel Guédras.—On the grouping of crystals of different species, by M. F. Wallerant.—On the development of the ovule in the Asclepiadeæ, by M. Paul Dop.—On the Nubian Sandstone, by M. R. Fourtau.—On the nature of the electric currents of the nerve, by M. B. E. Wedensky.—The *rôle* of the adipogenic function of the liver in the invertebrates, by Mlle. C. Deflandre.—On the existence of arsenic in the animal kingdom, by M. Gabriel Bertrand. The animals examined ranged from the higher vertebrates to the sponges, and in all cases small amounts of arsenic were found. The author concludes that this element forms a fundamental constituent of protoplasm, and points out the bearing of this fact in medico-legal cases.—Remarks on the preceding paper, by M. Armand Gautier. Arsenic is found to be specially localised in the ectodermic organs. It is not peculiar to the animal kingdom, as it has been found in certain Algæ and is probably present in sea water.—On the preparation of a pulverulent sulphur directly miscible with copper solutions, and on the simultaneous treatment of vineyards against oidium and mildew, by MM. A. and M. Campagne.—On the working and feeding of the fountain of Vaucluse, by M. E. A. Martel.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 20.

ROYAL SOCIETY, at 4.30.—Report on the Recent Eruption of the Soufrière in St. Vincent and of a Visit to Mont Pelée. Part I.: Dr. Tempest Anderson and Dr. J. S. Flett.—On the Correlation of the Mental and Physical Characters in Man. Part II.: Miss A. Lee, Miss M. A. Lewenz and Prof. K. Pearson, F.R.S.—Contributions to a Theory of the Capillary Electrometer. II. On an Improved Form of Instrument: G. J. Burch, F.R.S.—An Experimental Determination of the Variation of the Critical Velocity of Water with Temperature: Dr. E. G. Coker and S. B. Clement.

LINNEAN SOCIETY, at 8.—Digestion in Plants: Prof. Sydney H. Vines, F.R.S.—Relation of Histogenesis to Tissue-Morphology: A. G. Tansley.—Stelar Structure of Schizæa and other Ferns: L. A. Bondle.

FRIDAY, NOVEMBER 21.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Adjourned Discussion upon Captain C. C. Longridge's Paper on Oil Motor Cars of 1902.—And, *time permitting*, Recent Practice in the Design, Construction and Operation of Raw Cane Sugar Factories in the Hawaiian Islands: J. N. S. Williams.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—What is Climatic Disease: Lieut.-Col. A. M. Davies.

MONDAY, NOVEMBER 24.

INSTITUTE OF ACTUARIES, at 5.—Inaugural Address by the President, Mr. W. Hughes.

SOCIETY OF ARTS, at 8.—The Future of Coal Gas and Allied Illuminants: Prof. Vivian B. Lewes.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Explorations in Western China: Capt. C. H. D. Ryder, R.E.

TUESDAY, NOVEMBER 25.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed*: Electric Tramways: C. Hopkinson, B. Hopkinson and E. Talbot.

ANTHROPOLOGICAL INSTITUTE, at 8.15.—Anthropometric Investigations among the Native Troops of the Egyptian Army: Dr. C. S. Myers.—The Oldest Bronze Age Ceramic Type in Britain: Hon. J. Abercromby.

WEDNESDAY, NOVEMBER 26.

SOCIETY OF ARTS, at 8.—Le Tunnel du Simplon, et la nouvelle Ligne de Chemin de Fer Directe Anglo-Italienne pour l'Orient: Prof. Gustave Goegg.

THURSDAY, NOVEMBER 27.

ROYAL SOCIETY, at 4.30.—*Probable papers*:—Experiments on the Effect of Mineral Starvation on the Parasitism of the Uredine Fungus *Puccinia dispersa* on Species of Bromus: Prof. H. M. Ward, F.R.S.—Note upon Descending Intrinsic Spinal Tracts in the Mammalian Cord: Prof. C. S. Sherrington, F.R.S., and Dr. E. E. Laslett.—The Inter-relationship of Variola and Vaccinia; with Special Reference to the Possible Derivation of Cow-pox from the Inoculated Form of Small-pox in Man: Dr. S. MEDIÆVAL GEOGRAPHY.

The Dawn of Modern Geography. Part ii. A History of Exploration and Geographical Science from the close of the Ninth to the Middle of the Thirteenth Century (*c.* A.D. 900–1260). Pp. xix+651. By C. Raymond Beazley, M.A, F.R.G.S. (London: John Murray, 1901.) Price 18*s*.

IN the present volume of Mr. Beazley's work on the beginnings of modern geography, the author takes us from the time of the irruption of the Northmen into the Middle Sea to the days of the first western travellers in the Far East, the precursors of the Polos. He traces the gradual and painful regaining by the semi-barbarians of the early Middle Age of the earth-knowledge which their civilised forefathers had possessed, but which had been lost during the Dark Ages, until all that had once been known was known again and renascent Europe stood on the brink of discoveries of which Phœnicians, Greeks and Romans had hardly dreamed; with Marco Polo, Prince Henry the Navigator and Columbus, the third part of Mr. Beazley's work will deal.

The central fact of this period, as Mr. Beazley makes quite clear to his readers, is the Crusades. That the attack of Western Europe on the East was inspired by the spirit of the Northmen there can be little doubt. The urging of the Church would have fallen upon deaf ears had there not been abroad in the world a spirit of adventure and aggression, a will to dare and to do, which the older world had not known. This was not the spirit of Roman conquest, for it was ignorant, and had no definite consciousness of a mission to absorb and to reorganise; its desire was to do battle with the unknown, to court danger and to win renown in mortal combat with the devils and sorcerers of the East, the Paynim followers of Mahound, who was to all intents and purposes identified with the Arch-Fiend himself. If Mediæval Europe did not get this spirit of attack from the Romans, still less did she get it from their barbarian conquerors. The Ostrogoth and the Vandal, having overthrown the Empire, were suffocated and buried in its ruins. The Dark Age followed. Western Europe lay stupid, immobile, almost without an idea. Suddenly the inspiration came like a keen wind from the North; the Scandinavian descended in his multitudinous keels upon all the coasts of Europe; he conquered half England and a good part of France, he beleaguered Paris four times in forty years, he swept with the wind in his sails through the Straits and into the Middle Sea, he waged war in Sicily, and finally established himself in Miklagarth ("the great city," Constantinople) itself as the chosen *Vaering* or protector of the Byzantine Emperor. Here he held out a hand to his brethren who had imposed their rule upon the Slavs of Russia, and so the Roman world was girt about and shot through and through with the spirit of the Vikings. And by this time Roman Europe had itself influenced the Northman; it had Christianised him. He became as fierce a Christian as he had been a heathen. He gave to Christian Europe the spark of virility, the desire to dare and to do the uttermost for its faith, which it had lacked; it was now ready for the colossal adventures of the Crusades.

Mr. Beazley does not lay so much stress upon the Scandinavian origin of the Crusading spirit as we have done; with what he says, however, on p. 137, as to the general results of the Crusades we are in entire agreement. As he remarks,

"the land-travels of men who started from the Latin Kingdoms of the East" undoubtedly "led to a decisive and abiding extension of knowledge and civilisation. . . . European life was not impoverished, but enriched by the religious wars; and the only doubt must be whether it was necessary through such tribulation to enter into the brighter age of the great discoveries."

On pp. 407, 408, Mr. Beazley proceeds to exhibit one of the most striking results of the Crusades, and that one which marks a third epoch in the progress of geographical knowledge—the rise to power of the maritime republics of the Mediterranean. They supplied the necessary transport to the Crusaders, and so

"by serving the cause of Christendom they served their own; they multiplied, many times over, their carrying trade; they largely increased their export and import commerce; above all, they acquired a privileged, a more than half political, position on the coasts of the Levant. As time went on, and they became more indispensable to the Crusading princes, they were able to dictate their terms more freely, until the main burden of the Holy War rested upon them as the chief holders of power."

Thus were laid the foundations of the power of Venice and Genoa in the Nearer East, which for many centuries warded off from Western Europe the danger of Mohammedan conquest; Venice remained to the last a Crusading State, even down to the beginning of the eighteenth century, when her successful defence of Corfu under Schulemburg marked the final failure of the return-attack of the Crescent upon the Cross. From that siege dates the political decadence of Islam, and with it the political mission of the Venetian Republic also came to an end; there was no further need for her existence.

Even before the period of the Crusades, the Holy City had been the magnet which attracted hundreds of pilgrims from the West, despite the dangers of the way and the tyranny of the Saracen; the scanty accounts of their travels which have come down to us are of the greatest possible value as showing how knowledge of the Eastern Lands was gradually and painfully regained for the West; the epoch of the Crusades itself is naturally rich in such accounts of pilgrim-journeys. The impulse to far-journeying which was given by the Crusades naturally gained largely in strength in the post-Crusading period; emissaries of the republics and kingdoms of the West penetrated far into the East, and the Holy See itself did not hesitate to dispatch its representatives to the court of the Grand Cham of Tartary. These last missions were, however, hardly of the same character as those of Przhevalski or Sven Hedin; they were dictated by no desire of discovery or longing for more knowledge—for this we have to wait until the time of Prince Henry the Navigator—their aim and object was simply and solely to urge the Mongols, who were now shaking the Muhammedan power in the East to its foundations, to do the work which Christendom had been unable to do, and to destroy the common enemy of Christian and Heathen

alike. These missions, which are well described by Mr. Beazley (p. 275 *ff.*), added to geographical knowledge the outlines of a new chapter, soon to be filled up by Marco Polo.

It is noticeable that one or two of these missions, notably that of Rubruquis, were dispatched by Louis IX., King of France. Here we have the first hint of a new order of things; the domination of the Mediterranean republics in matters of commerce with, and discovery in, far-away lands was already threatened as early as the close of Mr. Beazley's period (about the middle of the thirteenth century) by the rise of the new kingdoms of Western Europe.

"As this period draws to a close," writes Mr. Beazley (p. 425), "the growth of great centralised inland kingdoms both in France and Spain was already foreshadowing a new period; when the most wealthy and unscrupulous of mercantile republics would find itself overmatched by superior resources and equal craft; and when, under the patronage of the new continental States, navies of even greater power would arise, and discoveries ruinous to Italian trade would be made in distant seas."

In fact, it was only the patronage of the Great States that made the discoveries of Prince Henry, of Columbus and of Cabot possible.

This, then, is the period of which Mr. Beazley's second volume treats; it begins with the descent of the Northmen, its central point is the Crusades, its end is marked by the impending eclipse of the trading republics by the organised power of the continental kingdoms. All else is in the nature of epilogue or addendum; the chapter on "Geographical Theory and Description" is as much an appendix as the "Appendix on Maps."

The author has known how to make his book extremely interesting; this is especially the case in the sections which deal with the deeds of the Northmen. He tells again the great story of the discovery of Vinland by Leif Ericsson of Brattahlid, of the coming of Thorfinn Karlsefne to Leif's Booths and the Long and Wonderful Beaches, of the fights with the Skraelings, of the birth of Snorre Thorfinnson, the first white American—that "finest story in the world" which should be known by heart by every Englishman, but which, we fear, is better known in Vinland itself than it is in England. He tells the tale well, and his discussion of the various theories as to the position of Vinland is very useful; he comes to the conclusion that Thorfinn's furthest south is to be placed at Mount Hope Bay in Massachusetts, in lat. 41° 24′ 10″. It is a pity that, as was of course to be expected in America, so many cranks and inexperienced 'prentice hands have busied themselves with a question which they are incompetent to solve, with the result that scientific investigation has not seldom fought as shy of Vinland as it has of Bacon-Shakespeare, anti-vivisection, or any other pseudo-scientific folly. We must, then, remember that even though the Writing Rock on the Taunton River is not a Runic inscription, but an Indian screed which "has certainly been tampered with in very modern times" (p. 75), though the Old Stone Mill at Newport is probably not more than two hundred years old and Longfellow's "Man in Armour" is a very doubtful piece of evidence, yet there is no doubt that the Norsemen reached the mainland of America and in all probability got as far south as Massachusetts, founding settlements there—shortlived indeed—as early as the closing years of the tenth century, and that the tradition of their discovery was never lost by their descendants in Europe.

The adventures of the "Jorsalafarers," of Saewulf the Englishman, of Sigurd Magnusson, King of Norway, of the monk Daniel of Kiev, and many other pilgrims to the Holy Places, are well told by Mr. Beazley; the gradual improvement in their geographical knowledge is very noticeable. Of remarkable interest are the travels of Benjamin of Tudela and his fellow-rabbi, Moses Petachia, in the Levant towards the end of the twelfth century; to them Mr. Beazley devotes a special chapter (p. 218 *ff*). To his description of the adventures of Rubruquis and other predecessors of Marco Polo in Tartary we have already alluded; in this connection we cannot but regret that he has made so very summary a reference to the very important journey of the Chinese Nestorian Rabban Bar-Ṣauma, born at Pekin, who was dispatched by the Tartar monarch Argôn in 1287 on an embassy to Constantinople, to the Pope and to the monarchs of the West in order to negotiate with them concerning an alliance for the reconquest of the Holy Land. Mr. Beazley's reference simply consists of a few lines in a footnote on p. 352, and he mentions Bar-Ṣauma merely as having been allowed by the Pope to celebrate Mass, &c. In reality his mission was very important, and the story of his journey to the West, his reception at Constantinople and at Rome, &c., as given in the Syriac "History of Mar Yahbh-Allâhâ and of Three Other Catholici and of One Priest and of Two Nestorian Laymen," is of very great interest. In the same note, Mr. Beazley spells the name of Mar Yahbh-Allâhâ "Mar Jabalaba." Presumably the second *b* is a misprint, but Mr. Beazley should have found out that the French spelling "Jabalaha" is barbarous. In the same way "Arghun" in the same note is wrong; it should be Argôn.

This brings us to the weak point in Mr. Beazley's work. He is manifestly unfamiliar at first hand with oriental sources, and he never seems to devote sufficient attention to what they can tell him about the period with which he is dealing. Thus in this volume of his book an account of Arab commercial activity and Arab contributions to geographical knowledge in the early Middle Ages is practically wanting; the subject is almost entirely relegated to a footnote on p. 462, and even there it is treated in a most summary manner. In a second edition, this note should be incorporated in the main text and considerably expanded. On p. 240, Mr. Beazley, speaking of the Assassins, says that

"the title of *Ismaelites* or *Ismaelians*, also applied to them, was derived from Ismael, seventh Imâm in the line of Ali, a descendant of whom became founder of the Fatimites."

This statement is incorrect so far as the descent of the Fatimites is concerned. Mr. Beazley should know that the Mahdi 'Obêdallâh, who founded the Fatimid dynasty, was in all probability an impostor, his descent from Ali being in the highest degree suspect.

On p. 192, the words "God most High" are in a foot-

note supposed to be translated into Arabic as "*Allah kebir*"; but this (which in any case would be ordinarily phrased "*Allah hu akbar*," "God is most great") means "God *is great*," and the phrase to which John of Würzburg is alluding is *Allah al-'âlî*, الله العلي, "God the Exalted," one of the hundred beautiful names of God. In a review of the first part of Mr. Beazley's work which appeared in these columns five years ago (vol. lv. p. 555), comment was made on the curious manner in which the author often spelt oriental, and especially Arab, names; in the present volume he seems to have taken the hint then given him, and does his best to avoid Gallic misspellings of the "Jesus Jabus" or "Doul-Karnain" type, but we still find such an unscientific transliteration as "Shaykh" (p. 239) for *shêkh*, and such a distinct mistake as "Magreb" (p. 264) for *Mâghrib*; the word is spelt with the guttural *Gh*ain, not with a *G*im. Most English writers will spell Semitic names correctly enough, but will go irretrievably wrong over a Russian or Polish appellation; Mr. Beazley, however, apparently finds Arabic or Syriac words difficult, while his spelling of Slav names is always unimpeachably correct.

In fact, when he returns to subjects with which he is thoroughly familiar, we find Mr. Beazley as valuable and as interesting as before, *e.g.* in the section of chapter vii. which deals with the geographical work of Adam of Bremen, who, as a clerk at the court of the great Archbishop Adalbert (d. 1076), was in the best possible position for gathering in the varied lore of the seafarers of the North for use in a geographical treatise. Of this lucky position he made the best possible use, and the result is that his tract "On the Position of Denmark and of Other Regions beyond Denmark" is of prime importance in the history of geography.

The appendix on maps is hardly so good as it might have been. Mr. Beazley praises the Mosaic Map of Madaba very highly (p. 580), but to us it hardly seems to merit such praise; it suffers in the first place from being executed in mosaic, and can hardly be taken to give us a very good idea of what the maps of the old Imperial period were like. On the same page Mr. Beazley says that in this map "we have one of the oldest pictures yet discovered of Jerusalem (outside the Egyptian and Assyrian monuments)." This passage has puzzled us considerably, for there is no representation of Jerusalem upon any Egyptian monument whatever, not even one of the time of Sheshenk I. (Shishak), and the Assyrian bas-relief of a town with a name ending in . . . *alammu*, which exists in the British Museum, cannot be identified with Jerusalem with any confidence. Perhaps Mr. Beazley is thinking of the reliefs representing Sennacherib's siege of *Lachish*. In his next edition the misleading phrase between brackets should be deleted. Mr. Beazley does not give many references to modern experts in antique cartography; as in the former volume, no mention is made of the name of the late Mr. Coote, for example. In the review of the first volume it was stated that "the revision of the whole of chapter vi. [of vol. i.], on 'Geographical Theory,' together with Mr. Beazley's account of the history and use of mediæval maps for the whole book—although Mr. Beazley omits to state the fact—is due, we understand, to Mr. C. H. Coote, of the Map Department of the British Museum."

Mr. Beazley seems to have odd ideas as to the function of a footnote; he often uses it to convey some little piece of further information which could perfectly well have been inserted in the main text, *e.g.* on p. 130 we read that of the Crusade of Siegfried Archbishop of Mainz, out of "seven thousand only two[1] returned"; on referring to note[1] we find the laconic addition "thousand." There are other instances in the book of the same peculiarity.

Finally, we must, as before, protest against the insufficient indices with which Mr. Beazley provides his successive volumes. No doubt he will give us a proper index to the whole work when it is completed, but meanwhile we have nothing but a "short index of names," which is of little use. It would have been a better plan to have provided a full index for each volume.

Generally speaking, then, the chief fault we have to find with Mr. Beazley is his manifest unfamiliarity with Eastern matters, which sometimes causes him to make serious mistakes when dealing with the oriental side of his subject. For all else he is excellent, and, moreover, he has written a most interesting book.

SOIL AND SANITATION.

The Earth in Relation to the Preservation and Destruction of Contagia, being the Milroy Lectures delivered at the Royal College of Physicians in 1899, *together with other Papers on Sanitation.* By George Vivian Poore, M.D. (Lond.), F.R.C.P. Pp. 257. (London: Longmans, Green and Co., 1902.)

THIS book is the work of an enthusiast, but to find fault with enthusiasm in these days of rapid progress and fresh discoveries would be unwise. Mr. Rider Haggard, with his watchword "Back to the Land," and Sir Seymour Haden, with his advocacy of "superficial and coffinless burial," are both enthusiasts. Who will venture to say that Mr. Rider Haggard or Sir Seymour Haden or Dr. Vivian Poore are idle dreamers? None dare say this, and if in some directions the writer of this review ventures to dissent from Dr. Poore's conclusions, it must be understood that he does so in a spirit of tolerant sympathy with the author's main contentions.

In the first six chapters, the distinguished author seeks to show that such diseases as tetanus, anthrax, diarrhœa, dysentery, cholera, Malta fever, malaria and enteric fever have not been proved to be "soil diseases" in the proper sense of the term. That is, that the prominent part assigned to soil in the spread of disease among human beings is largely speculative in character. At the same time, the author freely admits that contaminated soil may occasionally (accidentally, as it were) be the means of causing isolated attacks or even localised outbreaks of certain diseases. Nevertheless, he refuses to regard the soil as a "breeding ground" for pathogenic microbes or as capable of exerting any sustained power of spreading disease. On the contrary, he considers the soil effective in bringing about the dissolution of harmful germs.

Chapter vii. deals with the Maidstone epidemic, and is an intelligent, but not wholly unbiassed, criticism of the

conclusions arrived at by the experts engaged in the inquiry. The author says :—

"The epidemic is remarkable, not only for its severity, but from the fact that six gentlemen, all eminent for their skill in bacteriology, failed to discover a single typhoid bacillus."

The failure to isolate the typhoid bacillus was in no way remarkable ; it is a matter of real difficulty to discover its presence in a typhoid stool. At Maidstone, the pollution of the implicated water with microbes of excremental origin was abundantly proved, and no bacteriologist of repute would consider that failure to isolate *B. typhosus* from an implicated water afforded any proof whatever that this microbe was in reality absent.

Chapters viii., ix. and x., dealing respectively with immunity, practical considerations and agriculture, contain many thoughtful passages. But the author, in the pursuit of his main thesis, which may briefly be described as a plea for the methodical deposition of fæces on well-tilled humus, advocates measures which, as regards water supply, are open to some objection. But few will find fault with expressions of opinion such as the following :—

"Apart from the question of food-supply, it is, I believe, absolutely necessary to encourage agriculture in order that our race may be maintained in vigour."

"Anything which discourages or increases the difficulties of agriculturists can hardly be in the interests of the public health."

Chapter xi., on the maintenance of the fertility of the soil, is of considerable interest. The author quotes Sir William Crookes's famous address to the British Association (1898), a fragment of which may here be cited :—

"In the United Kingdom we are content to hurry down our drains and watercourses into the sea fixed nitrogen to the amount of no less than 16,000,000*l.* per annum."

True ; but in how many million pounds of adventitious material is this store of potential wealth concealed? Moreover, it may be good economy to allow to run to waste a potentially valuable substance if its retention (assuming questions of practicability and commercial gain) involves serious risk of danger to human beings.

In chapter xii., Dr. Poore interests the reader with an instructive account of sanitation in Holland.

Practical sanitarians would do well to read chapter xiii., describing the experiments conducted under the auspices of the city of Manchester as regards the disposal of refuse on Carrington Moss. The case may be an exceptional one, but the figures given by Dr. Poore are most instructive.

Dr. Poore's conclusions are given in chapter xiv., which contains also an interesting account of the author's experiments at Andover, in which the ordure and refuse of about 100 persons have been applied for fourteen years to rather more than one acre of land with conspicuous success as regards the amount of produce extracted from the soil. The author, by implication if not by direct statement, appears to consider that what is, under the superintendence of a master spirit, possible and practicable in the country must of necessity apply also to the complex conditions attending the disposal of excremental matters in the neighbourhood of large towns. The remark that

"the nineteenth century closed with the spectacle of a Royal Commission still discussing the best way of *destroying* the potentialities of life and prosperity"

might well have been omitted ; and it is to be regretted that the writer throughout his book so often seems to view a grave and serious problem through the wrong end of the telescope. But opinions such as the following will excite the sympathy of many readers :—

"At present he who advocates any attempt to entice a fair proportion of the people 'back to the land' is regarded as a Utopian dreamer. I feel convinced that the only chance of getting a living from agriculture lies in the due enrichment of the soil."

Chapters xv. to xviii. deal with an address to the Royal Medical and Chirurgical Society on enteric fever, and in chapters xix. to xxii. various papers on sanitary matters by the author are considered. They contain much useful and original information, and will repay careful perusal.

In conclusion, it may be said that the book is a noteworthy one. It is the work of a distinguished physician, an original thinker, and a lucid and polished writer. It is not free from defects, some dogmatic statements and one-sided opinions ; and the author's sanitary teachings do not always seem to the writer of this review to be of a wholly sound character. But a colourless reproduction of orthodox doctrines and the opinions of other men makes dull reading ; and no one who studies the book will regret having done so, nor will he fail to find in its pages many new and original thoughts, and fresh ways of interpreting old facts. That the book will add to the high reputation already enjoyed by Dr. Poore is certain.

A. C. HOUSTON.

STEEL-WORKS ANALYSIS.

The Analysis of Steel-Works Materials. By Harry Brearley and Fred Ibbotson. With Illustrations. Pp. xv + 501. Price 14*s.* net. (London, New York and Bombay : Longmans, Green and Co., 1902.)

ANALYSIS in the laboratories attached to works necessarily differs widely from the analysis of schools or that of research. To compare them is to compare the work of professionals with that of amateurs. The works chemist is already familiar with the methods he has to use, as well as with the general principles on which they are based, before he begins his daily round of endless determinations. Consequently, the best book for him will, in general, be shorn of philosophic considerations, of lengthy descriptions of ordinary manipulations, and of accounts of obsolete processes, though they may be of great educational value and historical interest. He needs a terse, accurate description of processes that he can use, with references to the difficulties that may be encountered and to the limitations that cannot be avoided. He must be able to find out quickly all that he wants to know, and he must not be misled. It is difficult to imagine a book which would be equally suitable for schools and works, but most treatises on analysis are compromises. The book now under review, which, by the way, is the second

on the subject that has emanated from Sheffield, is no exception to the rule, though certainly better adapted for steel-works chemists than for students.

The book is divided into thirteen parts—the first four, containing 185 pages, being devoted to the chemical analysis of iron and steel and their alloys; and the succeeding five, comprising 45 pages, to the analysis of refractory materials, slags, fuel, boiler water and scales. These are of the greatest value. In the preliminary summaries placed at the beginning of each section, a general view of the various methods is given which will be found extremely useful in aiding the chemist to decide on his course of action in any particular case. The methods are described carefully and in sufficient detail, without needless repetition and with a freedom from error which cannot be too highly praised. Especially interesting are the pages devoted to rapid analysis at the furnace. Cases arise, for example, in the preparation of armour plates when the percentage of a number of elements must be determined while the charge of fused metal is still in the furnace. It will be a matter for surprise to many analysts that an expert operator was found to occupy only eight and a quarter minutes in the estimation of manganese, and that twelve minutes is considered enough for the estimation of silicon.

Part x., dealing with the analysis of the alloys of copper and the "white metals," is little less satisfactory than the preceding parts, but the remaining sections show a distinct falling-off from the high standard reached in the earlier pages. The micrographic analysis of steel is not well described. The lack of detail and some misleading statements prevent the article from being of use to a beginner, and an experienced worker will find nothing here to help him, except in the bibliography, which, unfortunately, stops short in the beginning of the year 1898! The illustrations are poor, perhaps owing to the fact that most of them are not photographs, but merely hand sketches, and the absence of reproductions of the structures to be observed under high magnifying powers is noticeable. The weakest part of the book, however, is the meagre and unpractical account given of pyrometry, which is not written by either Mr. Brearley or Mr. Ibbotson. Only the Le Chatelier thermocouple is described, and the modern forms of pyrometers in which it is used, as well as other types of instrument, are either ignored or barely mentioned. A clumsy and inconvenient method of recording the indications of the thermocouple is described, a method which was devised some years ago and abandoned everywhere, unless it is still in use in Sheffield, within a few months of its introduction. In future editions, this section should be either omitted or revised and extended.

At the end, there is a valuable bibliography of papers on steel-works analysis, which occupies 139 pages and seems to be fairly exhaustive. It is compiled by Mr. Brearley, and includes papers which appeared up to the end of 1901.

The book, in spite of its uneven merit, can be confidently recommended. The publishers have done their part of the work well in all respects. The authors write readable English, with a touch of the vigour on which Sheffield prides itself, manifested, for example, in a certain contempt for what they are pleased to call "hoary assertions."

LECTURES ON CELESTIAL MECHANICS.

Die Mechanik des Himmels. Vorlesungen von Carl Ludwig Charlier, o. Professor an der Universität Lund. Erster Band. Pp. viii + 488; mit zahlreichen Figuren. (Leipzig: Veit and Co., 1902.) Price Mk. 18.

THE number of text-books on the subject of celestial mechanics is by no means so large but that an addition ought to be warmly welcomed. More especially is this the case when the author is one who has himself made many valuable contributions to this difficult branch of analysis. Prof. Charlier's original work is characterised by great clearness and, as far as possible, simplicity. These qualities are not wanting in the lectures which he has delivered in the University of Lund since the autumn of 1898, and of which a first volume is now published. One cause for some regret may perhaps be mentioned. Prof. Charlier has shown, in several papers which he has recently published, that he can write excellent English. It is a pity, from our point of view, that in the case of his lectures he has preferred to publish in German, for there does not exist in our language a work of the same scope. Let it be said, however, that the German is exceptionally simple and should cause little difficulty to a reader whose knowledge of the language is slight.

The scheme of the lectures is to give a simple exposition of the present position of researches in celestial mechanics, so far as the motions studied do not depend on the dimensions and figures of the celestial bodies. In the selection of his subject-matter, the author's aim has been two-fold, namely, to lay stress on the results of the greatest astronomical importance and to illustrate the clearness and elegance characteristic of modern methods of analysis. The numerical examples which have been introduced for the sake of the former object might, perhaps, have been augmented with advantage. Prof. Charlier freely acknowledges the incompleteness of his work, and finds an explanation in the transition period in which astronomy stands and in which it is difficult to distinguish what is essential from what is unessential. The excuse is unnecessary, for it would be unfair to expect a systematic treatise in what does not pretend to be more than a course of lectures. And as such the book will be found interesting and suggestive, because it forms an introduction to recent developments of theory which have in many cases been accessible only in the original memoirs themselves.

The scope of the work will be best understood by a brief glace at its contents. This first volume contains the results of a more general character in the problems of two and three bodies. It is divided into seven sections. The first section contains preliminary theorems in pure mathematics and mechanics which would probably be familiar to the class of English reader who would attempt to use the book. At least, this is so in the case of paragraphs dealing, for instance, with the theory of determinants, the properties of functional determinants, linear substitution and Lagrange's equations. Yet it is useful to have such theorems actually at hand for reference, especially in a book which is genuinely

elementary in the sense that no excessive demands are made on the reader's knowledge at the outset. Here is introduced the canonical form of equations which is destined to play a predominant part in the sequel, and earlier is a sketch of the theory of linear differential equations with periodic coefficients as developed by Hermite, Floquet and Poincaré.

In the second section, the partial differential equation of Jacobi is discussed and Stäckel's important theorem on the possibility of solving it by separating the variables is given. This leads to the consideration of motions determined by one degree of freedom, and in particular of forms of motion termed "Libration" and "Limitation," the latter being of the nature of Poincaré's asymptotic solutions. An account follows of conditionally periodic motions, based on the researches of Staude.

The third section treats of the motion of a particle attracted by two fixed Newtonian centres of force. This problem provides illustrations of the theory of the previous section. Otherwise it is a little inconsistent with the practical aim of the author, for its astronomical interest, as was frankly admitted by Lagrange, is very slight. A reference might here have been made to Prof. Greenhill's paper on the stability of such forms of motion (*Proc.* Lond. Math. Soc., vol. xxii.).

The problem of two bodies is treated in some detail in the fourth section, the Hamilton-Jacobi equation being made the basis of the discussion. The case of a repulsive force is also discussed, and this leads to a digression on the dynamical theory of the tails of comets.

The most important results in the general problem of three bodies are investigated in the fifth section. The general integrals and the different forms which they assume when expressed in different systems of coordinates are discussed. The method of variation of parameters is explained in conjunction with Jacobi's canonical elements and also in connection with relative coordinates. The chief results of Jacobi's classical memoir on the elimination of the nodes and of Laplace's theory of stability are given here. Finally, the equations of the problem are reduced to the form expressing four degrees of freedom.

The rest of the book is devoted to the theory of perturbations. In the sixth section, Poincaré's system of canonical elements is introduced, the form of the development of the disturbing function is described and a very brief sketch of Laplace's coefficients is given. The final section contains the theory of secular perturbations of a planetary system, which is treated in some detail. At the end of the volume will be found some useful numerical tables.

The second volume is promised for next year. It will contain the theory of periodic orbits in the problem of three bodies and researches on the convergence of series.

H. C. P.

OUR BOOK SHELF.

Lexikon der Kohlenstoff-Verbindungen. By M. M. Richter. Pp. 2482. (Hamburg: Leopold Voss, 1899.) Price, 39 parts, 1.80 marks each.

NOTHING could illustrate more forcibly the rapid growth of organic chemistry than the increased dimensions of the new edition of Richter's "Tabellen der Kohlenstoff-Verbindungen," published in 1884, which now appears for the first time under the title of "Lexicon."

The first edition, the publisher tells us, accounted for 16,000 compounds; in the present volume, which is brought down to the first quarter of 1899, 67,000 compounds are described, so that in fifteen years organic chemistry may be said to have multiplied more than fourfold. It is not surprising to learn that the stupendous labour of collecting and arranging this enormous mass of material has taken ten years to complete.

The lexicon contains all the known carbon compounds, arranged in order of their molecular formulæ on an ingenious system, which is fully set forth in the introduction. The name and a few physical constants are given, but the chief information is contained in the very full references to the original literature and to Beilstein's well-known "Handbuch." Since the first edition of the book appeared, the nomenclature of the Geneva Commission has been introduced, and in many cases the new and the old names appear side by side.

There is also an index of the names of the different compounds at the end of the volume.

Where organic research is being pursued with the almost feverish rapidity which is in vogue, more especially in the German laboratories, involving in the process the production of many compounds, both old and new, it is easy to understand the time and trouble which might be expended in fixing the identity of these compounds. One object of the lexicon is to lighten the labours of the investigator in this direction.

This becomes more imperative where the number of isomerides is large, for it is not uncommon to meet with 50, 60, or even 100 substances with the same molecular formula. For example, an experimenter who happened in the course of his research to obtain a compound of the formula $C_7H_{10}O_4$ would be confronted with a choice of 59 substances among compounds already known. By reference to the lexicon, he would see from the physical properties whether the compound had already been prepared, or, failing this, he could at once refer to the literature on the subject.

Richter's "Tabellen" is sufficiently well known among chemists and its utility long enough proved to ensure an excellent reception for the new edition and to render superfluous any further description of its use or its merits.

The author complains (and who does not) of the present system, or lack of system, of chemical nomenclature.

Organic chemistry has, in fact, outgrown its mother-tongue. It can no longer express itself clearly in the language of its childhood. An attempt was made by the Geneva Commission of 1892 to introduce reforms, and some excellent proposals were made, and have since been to some extent adopted on the continent. The author adds, "it is and remains deplorable, the fact that the resolutions arrived at at Geneva have no prospect of being generally adopted." It is to be hoped that before many more thousands have been added to the still growing number of organic compounds, the confusion which is rapidly impending through the want of a universally recognised system of nomenclature will be averted by a complete and thorough revision, more especially of the names of ring compounds.

J. B. C.

Ueber Harmonie und Complication. By Dr. Victor Goldschmidt. Pp. 136; with 28 figures. (Berlin: Julius Springer, 1901.) Price 4 marks.

MANY attempts have been made to associate the forms occurring in music with forms which manifest themselves to senses other than that of hearing. If the term "harmony" is used to include all such groupings and arrangements as give us pleasure, then we have harmonies

of form, harmonies of colour, and so forth. Dr. Goldschmidt's object appears to us to be to reduce all such harmonies to a common formula, and he considers that the different kinds of harmony are governed by a common law, the "law of complication."

As an example of the arguments employed, a series of numbers is obtained from the intervals of the musical scale which coincide with numbers in another series alleged to be obtainable from crystallography. But the numbers in the case of the music do not represent actual intervals, but are derived from them by a homographic transformation, according to which the keynote and its octave are represented by 0 and ∞ and the major fifth by 1, and the series is incomplete unless the minor seventh be included in the list. And the identity of the two series is by no means complete; for there are terms in the series derived from music which are absent from that obtained from crystallography.

It is easy to find connections as close as those dealt with in the present work between phenomena which have nothing whatever in common. For a considerable period, the number of wranglers in the Cambridge mathematical tripos was observed to be intimately related to the frequency of sun-spots, and anyone who should seek to establish a connection between the notes of the musical scale and the courses of a *table d'hôte* dinner might easily make out a very strong case. What is most surprising is that the analogy which *a priori* exists between musical intervals and colour intervals, both of which depend on ratios of vibration-frequency, appeals but little to our senses, so little, in fact, that certain writers have even sought to establish relations between chords and colours quite independently of the known relations of pitch. As for the connection which no doubt exists between a love of music and a talent for mathematics, its cause is not difficult to find. A mind like that of Beltrami, who could discover in the purely abstract ideas of geometry and algebra truths applicable to spaces other than that in which we live, was necessarily well trained to appreciate that beauty of form dissociated from worldly matters which exists in the sonatas and symphonies of the older composers. In order, on the other hand, to make it more palatable to a mind that wants to grasp something tangible, music is commonly associated with such mundane ideas as love, vice, battle and murder, and sudden death, the triumph of the victorious. the wails of the vanquished.

Opere Matematiche di Francesco Brioschi. Vol. ii. *Opere Matematiche di Eugenio Beltrami.* Vol. i. Pp. 456 and 437. (Milan: Ulrico Hoepli, 1902.) Price 25 lire.

THE second volume of Brioschi's works contains thirty-five papers contributed to the *Annali di Matematica pura ed applicata*, series 1 and series 2, vols. i.–xiv., between the years 1858 and 1887. These papers have all been carefully revised by Profs. Cerruti (Rome), Gerbaldi (Palermo), Loria (Genoa), Pascal (Pavia), Pittarelli (Rome), Reina (Rome) and Tonelli (Rome). A considerable number of them deal with linear differential equations, but elliptic and hyperelliptic functions, curvilinear coordinates, binary forms and many other subjects are treated; and the papers also include obituary notices of Borehardt and Chasles.

After the death of Prof. Beltrami, in 1900, the Faculty of Science of the University of Rome resolved to establish a memorial of the distinguished mathematician, and it was decided that the most fitting form for the memorial would be a complete edition of Beltrami's collected works; to quote Prof. Tonelli, *monumentum aere perennius.* In this case, the work of preparing the volumes has been carried out entirely under the direction of Profs. Cremona, Castelnuovo and Tonelli, as representatives of the Roman Faculty of Science, who have been aided by the collaboration of Profs. Bianchi, Burgatti, Cerruti, Dini, Pittarelli, Reina and Volterra. The order of arrangement differs from that adopted for Brioschi's works. Instead of being grouped according to journals, Beltrami's papers are arranged in strict chronological order, and this volume represents the work of eight years, from 1861 to 1868. That these first eight years of Beltrami's career as a mathematician were productive of work of great value is shown by the list of titles, which include researches on analysis applied to geometry, the flexure of ruled surfaces, resolution of the problem of transforming geodesics on a surface into straight lines in a plane, complex variables on any surface, fundamental theories of space of constant curvature, and last, but not least, the "Saggio d'interpretazione" of non-Euclidean geometry. The portrait of Beltrami which forms the frontispiece is due to Prof. Pittarelli.

Beltrami's works are published in uniform style with those of Brioschi, and both are printed by the Mathematical Press, of Palermo.

Handbook of the Trees of New England. By L. L. Dame and Henry Brooks. Pp. xv + 196. (Boston, U.S.A.: Ginn and Co., 1902.)

THE interest connected with the flora of the New England States lies in the fact that situated between Canada and the Alleghany Mountains they furnish the meeting point of a northern and a more southern flora. Since the book is limited to such a relatively small part of the country, it does not possess the general interest which would attach to one which included, for instance, the trees of all the eastern States. What it loses in comparative value, perhaps it gains in definiteness; it contains useful and succinct descriptions, good illustrations specially drawn, and states the horticultural value of all the indigenous species. The Latin nomenclature is satisfactory and correct, except in the case of a species of Acer, and for *Quercus Muhlenbergii*, which is considered by some authorities to be a variety of *Quercus prinus*; but the popular names are in utter confusion, and we cannot agree with the authors that it is wiser "to record what is, and not what ought to be." Taking *Populus balsamifera* as an illustration, the names recorded are "Balsam. Poplar. Balm of Gilead." Now this tree is certainly not a balsam, and *Populus candicans* is the real Balm of Gilead; while the name balsam-poplar would be sensible and correct. Apart from this and within its limits, the book may be recommended either to enable one to identify the trees or to ascertain their characteristics. English readers will find that only about half-a-dozen species are the same as those indigenous to this country.

Lake-Country Rambles. By William T. Palmer. Pp. viii + 334. (London: Chatto and Windus, 1902.) Price 6*s*.

MR. PALMER has here collected a series of papers he has from time to time contributed to various magazines. For many years the author has been a rambler in the lake-country, and has learned to love its inhabitants and to study its varied scenes. The essays are good examples of descriptive writing, but the aspects of nature and the incidents of outdoor life are treated rather from the point of view of the general observer than that of the inquiring naturalist.

Junior Arithmetic Examination Papers. Arranged by W. S. Beard. Pp. vi + 106. (London: Methuen and Co., 1902.) Price 1*s*.

THE ninety examination papers contained in this collection cover all the parts of arithmetic generally studied in schools. The first third of the papers gradually increase in difficulty from paper 1, on the first four rules, to paper 30, on the mensuration of rectangular solids. The remaining papers are made up of mixed questions and are all well graduated. The questions should be useful to teachers.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Classification of Quartic Curves.

THE best method of classifying curves is to commence with one which is founded on properties which are unaltered by projection. We thus obtain ten principal species of quartic curves, viz. *anautotomic, uninodal, unicuspidal, binodal, nodocuspidal, bicuspidal, trinodal, binodocuspidal, nodobicuspidal* and *tricuspidal*; but each of these species admits of a variety of subsidiary divisions, owing to the fact that all curves of a higher degree than the third may possess compound singularities.

Anautotomic, unicuspidal, bicuspidal and tricuspidal quartics admit of a subsidiary division depending on the number of points of undulation they possess; and it must be borne in mind that, although it is convenient to use the term point of undulation, it is the tangent at this point and not the point itself which is the actual singularity.

Uninodal quartics admit of *three* primary subdivisions, according as the double point is an ordinary node, a flecnode or a biflecnode.

Binodal quartics admit of *seven* primary subdivisions, six of which depend on the character of the node, whilst the seventh arises from the fact that the two nodes may unite into a tacnode.

Nodocuspidal quartics admit of only *four* primary subdivisions, three of which depend on the character of the node, whilst the fourth arises from the fact that the node and cusp may unite into a rhamphoid cusp.

Trinodal quartics admit of *ten* primary subdivisions, and in order to particularise them, we shall denote the different singularities which involve a double point by their initial letters, except that *tp* and *tc* will be used to denote a triple point and a tacnode cusp respectively; so that the nomenclature n, n, n and n, n, f will indicate that the quartic has three nodes or two nodes and a flecnode respectively. We shall then have the following ten species:—(1) n, n, n; (2) n, n, f; (3) n, n, b; (4) n, f, f; (5) b, b, b; (6) t, n; (7) t, f; (8) t, b; (9) o: (10) *tp* of the first kind.

Binodocuspidal quartics admit of *eight* primary subdivisions, which are as follows:—(1) c, n, n: (2) c, n, f; (3) c, f, f: (4) t, c; (5) r, n; (6) r, f; (7) *tc*; (8) *tp* of the second kind.

Nodobicuspidal quartics admit of *three* primary subdivisions, which are:—(1) c, c, n; (2) c, r; (3) *tp* of the third kind.

Whenever any of these primary species represents a curve which has two or more points of inflection, a further subdivision may usually be made which depends upon the number of points of undulation it can possess. Thus the species n, n, n may possess two, one or no points of undulation; whilst the species c, c, n may possess one or no such points.

A fourth subdivision may sometimes be made which depends upon whether the quartic is capable of being projected into a curve which is symmetrical or hemisymmetrical with respect to a pair of rectangular axes. In some cases, the possibility of the projection involves the existence of compound singularities, and thus the curve belongs to one of the species already considered; but in other cases, the necessary conditions do not affect the singularities. Thus all trinodal quartics which are capable of projection into symmetrical curves must belong to the species n, n, b; b, b, b; or t, b, in which three respective cases the quartic can be projected into the inverse of an ellipse or hyperbola with respect to its centre, the lemniscate of Bernoulli or the lemniscate of Gerono. On the other hand, the possibility of projecting any quartic with three double points into a hemisymmetrical curve depends upon whether it can be projected into the inverse of a conic with respect to a point in its axis. The conditions for this do not necessarily involve compound singularities, since these will only exist for special positions of the centre of inversion.

There is no necessity to adopt a classification founded on the nature of the branches at infinity, since all the results can be obtained by projection. Thus, if a straight line cutting in four real points any quartic, which is unipartite and perigraphic, be projected to infinity, the projection will be quadripartite and will have four real asymptotes; and by taking special positions for the line to be projected, a variety of special results can be obtained. By projecting a triple point or a pair of crunodes to infinity, it is at once seen that a quartic can have three parallel or two pairs of parallel asymptotes. Also, if the polar cubic of a point o breaks up in to a conic and a line cutting the quartic in four ordinary points and the line be projected to infinity, the projection will have four asymptotes meeting in a point.

A quartic having three acnodes is the limiting form of an anautotomic quartic in which the acnodes are replaced by three perigraphic curves; and if a line cutting the fourth portion in four real points be projected to infinity, the projection will be septipartite. From this it appears that the partivity of a curve of the nth degree cannot be less than $n+\frac{1}{2}(n-1)(n-2)$.

Fledborough Hall, Holyport, Berks, November 14.

The Conservation of Mass.

APROPOS of the recent discussion on the conservation of mass at the Belfast meeting of the British Association, the following calculation may be of interest; it relates to the loss of weight undergone by a body when raised vertically.

If g is the acceleration of gravity at a specified point on the surface of the Earth, m the mass of a body of weight w, then

$$w=mg.$$

Now let the centre of gravity of the body be raised through a vertical distance d; g will be changed into

$$g'=\left(\frac{\mathrm{R}}{\mathrm{R}+d}\right)^2 g,$$

R being the radius of the Earth (supposed spherical), and the corresponding weight of the body will be

$$w'=mg'$$

on the supposition of the conservation of mass.

The loss of weight is thus

$$\delta=w-w'=w\left\{1-\frac{\mathrm{R}^2}{(\mathrm{R}+d)^2}\right\}$$

$$=w\left\{1-\left(1+\frac{d}{\mathrm{R}}\right)^{-2}\right\}=\frac{2dw}{\mathrm{R}},$$

neglecting second and higher powers of $\frac{d}{\mathrm{R}}$.

As a particular example, take $w=1$ kilogm., $d=10$ cm. and R approx. $=6357\times10^5$ cm.

Then

$$\delta=0{\cdot}00003 \text{ gm.}$$

[The term involving $\left(\frac{d}{\mathrm{R}}\right)^2$ would have the first significant figure in the fifteenth place, and therefore we were justified in this case in neglecting it.]

This small difference is, I believe, of the same order as those which Prof. Landolt found; but the ratio of the difference to the whole weight (*i.e.* $2d:\mathrm{R}$) must have been much greater in his experiments. Although Prof. Landolt's discrepancies may receive a perfectly different explanation, it is quite conceivable that a balance could be constructed which would detect such small differences. It is scarcely necessary to point out that, in the actual performance of the experiment, the scale-pan containing the counterpoising weights must be at the same height during the two weighings.

St. Andrews, November 12.

A Simple Experiment in Diffraction.

M. G. FOUSSERAU describes, in the *Journal de Physique* for October, a simple apparatus for viewing diffraction and interference phenomena, a modified form of which I have experimented on with success. In the latter form, the source of light was obtained by placing a diaphragm on the stage of a microscope, on which sunlight was concentrated by means of the mirror and condenser, and the diffraction effects were produced by placing perforated pieces of tinfoil on the top of the microscope tube where the eye-piece is usually placed. On placing the eye close up to the tiny hole in the tinfoil, various diffraction patterns were seen. The difficulty of piercing a hole that is truly circular in tinfoil made it hard to obtain perfect rings, but the "failures" were often very interesting. A rectangular aperture

was easily got by cutting slits in two pieces of tinfoil with a razor and placing one over the other with the slits at right-angles, while for a triangular aperture three strips of tinfoil placed so as to leave just a tiny triangle open gave good results.

G. H. BRYAN.

The Secular Bending of Marble.

THE fluidity of marble under pressure, of which Dr. See mentions an instance in NATURE (p. 56), has, I believe, been well established by laboratory experiments. Another instance of secular bending, similar to that quoted by Dr. See, was to be seen in two alabaster slabs which formed the jambs of a doorway in the Alhambra. Owing to the pressure brought to bear on these by the settlement of the building, they had bulged out from the wall by as much (if I remember right) as 6 or 7 inches. The slabs were about 7 feet long and a foot wide, their thickness being, perhaps, a couple of inches. Whether they are to be seen there still, or not, I do not know.

SPENCER PICKERING.

Summer and Winter.

CONCERNING the relation of summer and the following winter referred to on p. 63, a few facts from Greenwich records of the last sixty-one years may be acceptable. We find this:—

Summer warm,	winter severe,	9	cases.
,, ,,	,, mild,	19	,,
,, cold	,, severe,	17	,,
,, ,,	,, mild,	12	,,

(This leaves four cases with average values.)

It thus appears that warm summers have been distinctly more often followed by mild winters than by severe ones; but the difference in the other case, of cold summers, is less pronounced. In this representation, wet is left out of account, the mean temperatures of summer and winter being alone considered, and in relation to the averages. But we might limit our attention to summers that have been both cold and wet, as this last summer has been. (Cold summers have not always an excess of rain.) Of such there appears to have been nineteen. Now taking all those with a mean temperature under 60°·5 (the average mean temperature of summer below 61°·2), I find that nine were followed by severe winters and only three by mild winters; total, twelve. As the past summer comes in this group, the chances seem in favour of a severe winter.

A. B. M.

Personal.

I DID not think it worth while to correct an error into which the reporters of the ephemeral Press fell in prefixing the words "his own" to the word "work" in the account of my recent speech at Liverpool, where I had said that my new sphere afforded me a larger opportunity for work: simply.

I do not know how best to correct it, or whether it is now possible, but I see it has been reproduced in your University Intelligence on p. 70, and an error incorporated in NATURE is of rather permanent character, and may be misleading to my friends.

OLIVER LODGE.

Birmingham, November 21.

MATHEMATICS IN THE CAMBRIDGE LOCALS.

ON May 29 (vol. lxvi. p. 117), we announced an important change in the geometry of the *Oxford* local examinations for 1903. Quoting from the notice which had just been issued, attention was directed to the important statement that "Questions will be set so as to bring out as far as possible a knowledge of the principles of geometry, a smaller proportion than heretofore consisting of propositions as enunciated in Euclid. Any solution which shows an accurate method of geometrical reasoning will be accepted. No question will be set involving necessarily the use of angles greater than two right angles. Geometrical proofs of the theorems in Book ii. will not be insisted upon." We have now received the schedules in geometry that have been adopted for the *Cambridge* preliminary and junior local examinations in 1903. In these, we are glad to see that the Cambridge Syndicate has adopted to an even greater extent the reforms suggested by the recent British Association Committee. For the preliminary, junior and senior examinations:—"Any proof of a proposition will be accepted which appears to the examiners to form part of a logical order of treatment of the subject. In the proof of theorems and deductions from them, the use of hypothetical constructions is permitted." No schedule will be published for the senior examination. The importance of the schedules now published for the preliminary and junior examinations will be apparent when it is considered that they may be said to cover the work done by the boys and girls in all secondary schools up to the age of sixteen years, and the work of such older boys and girls as are not trying for marks of distinction. Their influence is great, and we heartily welcome the important change that they place much greater stress upon observation, measurement and experiment than on abstract reasoning. It is to be observed also that there is no mere pretence of accuracy:—"Every candidate must be provided with a ruler graduated in inches and tenths of an inch, and in centimetres and millimetres, a small set square, a protractor, compasses furnished with a hard pencil point, and a hard pencil." This mention of the hard pencil is business-like; as soon as boys understand that in their measurements of lines they must not make errors of even one-hundredth of an inch, their true scientific education begins. As for demonstrative geometry, a great number of Euclid's propositions are left out altogether. Books ii. and iv. have completely disappeared. Twenty-eight out of the forty-nine propositions of Book i. have to be studied for the preliminary and junior. Of the thirty-seven propositions of Book iii., only ten have to be studied for the preliminary and four more for the junior. Of the thirty-five propositions of Book vi., only thirteen are required for the junior. The most important part of the geometry examination is called practical geometry, and there is every inducement to all teachers now to dwell largely on experimental geometry, as all good teachers have done for many years.

We have reason to believe that in dealing with arithmetic, algebra and trigonometry, the syndicate will follow, as closely as it has done in geometry, the recommendations of the British Association Committee as drawn up by Prof. Forsyth. Should this be so, we are assured of a very great reform in the teaching of mathematics in all the secondary schools of England. This consummation will be further assured by recognition of the reform, which will surely come soon, on the part of the Civil Service Commissioners and all other examining bodies in the kingdom. We may say, then, that every average boy looking forward to a career in the Civil Service, in the Navy, in the Army, in any of the professions, will have had an incubus lifted from his life, and a much greater load will have been lifted from the spirits of his father and mother. Boys susceptible of being crammed for examinations will no longer have an unfair advantage over their far wiser and more sensible but reputedly stupid fellow competitors. There will, moreover, be a chance that boys from schools will be able to take better and fuller advantage of the instruction given in technical colleges.

To the educationist, the reform, however far-reaching in its results, may appear small; he may think that it should have been effected long ago. This view, however, does not in our opinion do justice to the services of the reformers. It leaves out of account the strength of the opposition. This reform needed that many men should work in an unhopeful, heart-breaking way for it for many years, and its importance is not diminished by its coming

at last quite suddenly, and as if miraculously, like the fall of the walls of Jericho.

In criticism of the schedules, we may perhaps be allowed to say that personally we wish the syndicate had not followed Euclid so closely. All the practical geometry of the syllabus is mere illustration of Euclid. There are, for example, other angles than 90° easily to be drawn; arithmetical computation and experimental mensuration give new avenues to geometrical ideas, and the more avenues we can offer to pupils the better. Where the syllabus says "division of straight lines into a given number of equal parts," there appears to us too much restraint. There is no reason why a line should not be divided into many parts in any proportions, and a most educational exercise it would be. And what is the use of hiding the fact that a "preliminary" candidate cannot be prevented from having a good working knowledge of Book vi., although it is wise enough to keep the demonstrations to a later stage? Any boy understands that maps may be drawn to different scales, and this is almost the whole of the sixth book of Euclid. As for construction of tangents to a circle and "construction of common tangents to two circles," we would let a student draw these without introducing any idea of difficulty and we would ask him, by dropping perpendiculars on tangents from centres, to find the real points of contact. As soon as a boy can draw a right-angled triangle, measuring the sides and using arithmetic to find sines, cosines and tangents, he ought to begin trigonometry. If he knows the mere definition of *tan* A, he ought at once, by merely exercising his common sense, to be able to draw the angle the tangent of which is given. A common-sense knowledge of right-angled triangles is really a knowledge of solution of triangles in general. But until the artificial bulkheads between the various water-tight compartments of mathematics are swept away, we suppose that it will not be possible to give to very young schoolboys the power to solve trigonometrical problems. If the syndicate would condescend to study the elementary syllabuses of Science Subjects I. and V_{p} of the Education Department, we think these courses of studies might become much easier and much more valuable.

But is not ingratitude the meanest of sins? And may it not show wisdom in the syndicate that it avoids changes which may seem to be too sudden and too great? Besides, it is to be recollected that almost every candidate who has followed this course has also taken a course in experimental science, into which weighing and measuring, the uses of squared paper and logarithms, and the ideas of the calculus have entered in all sorts of commonsense ways. Even taken by themselves, the schedules mark a great step in our experiment of finding a method of teaching mathematics suitable for boys of the Anglo-Saxon race. A beginning has been made in disenchanting the English school system of those pedagogic dogmas which have tied teachers and pupils hand and foot. Teachers and examiners will ask for more and more freedom as they find that it is altogether good. Hitherto, the average English boy has believed himself to be stupid because he was unable to reason about things unknown to him; hitherto, the average English teacher of mathematics has thought of himself as a dull, tired usher because he has had no interest in teaching; in future, pupils and teachers will feel with complacent pride that they have come to their inheritance as thinking, useful human beings. We look forward to very great results, and we are not going to give credit in particular to any one of the ten or twenty names that rise before us of the men who have helped to make this reform. Those who are dead had their reward in knowing that they helped towards a reform that was certain to come; those who are alive have the reward of knowing that they were commissioned to keep alight the torches lit by their much-loved predecessors.

With the exception of the Society of Arts, no institution of the country has been so successful in initiating scientific reform as the British Association. A Committee was appointed in 1874 (the present writer is proud to think he was a member of it) for improving science teaching in schools, and another for improving mathematical teaching, and although the members of these Committees were mostly men of influence, their efforts led to no important results for many years. But ten years afterwards, the report of a British Association Committee on the teaching of science acted on the scholastic world like the prince's kiss in the story of the Sleeping Beauty, and in 1901 the British Association proceedings in the new Education Section acted in much the same magical way in relation to the teaching of mathematics. Many mathematical masters were feeling hopeless about reform, but without jealousy, with great enthusiasm, with the most wonderful forgetfulness of differences in small matters, they joined together to assist the British Association Committee of Mathematicians. There can be no doubt that this evidence of a desire for reform among the schoolmasters had a great effect upon the members of the Committee who were not in immediate touch with the schools. All the tact, patience and resourcefulness of a chairman eminent for these qualities might have been unavailing in dealing with a Committee the members of which were all men of great individuality had it not been for the schoolmasters' memorial. Anyone who knows the history of this reform must recognise its peculiarly English characteristics—the conservative clinging to past methods because of the recognisable good in them, even among the most radical reformers; the efforts of individuals in low and high positions gradually making converts in spite of the seeming hopelessness of reform; the unwillingness of men in high positions to lend their names to the movement, the virtue of which they were aware of, so long as they thought that only unrest and disturbance could accompany it; and their concerted action as soon as it was evident that a great reform was possible. And now, because it has occurred in the English way, we know that the reform is real, that it will have a fair chance, that it will go on year after year for many a year to come. This is no case of a thin end of a wedge, for no force is really required. It would be bad policy to make too great a change at once. Freedom has been given to teachers, a freedom much sighed for, a freedom which will create enthusiasm. Those who are most determined to make the reform complete are most anxious to proceed cautiously and to smother intemperate zeal.

JOHN PERRY.

THE THEORY OF THE GAS MANTLE.

A NUMBER of papers have been recently published which deal, either directly or indirectly, with the cause of the high efficiency of the incandescent gas mantle.[1] Space does not permit us to enter at all fully into the details of these papers, but it is of interest to consider some of the questions which they raise.

The high luminosity of the mantle and its still more remarkable dependence on a particular composition have long been recognised as facts calling for some special explanation, and many have been the hypotheses advanced to account for them. The simplest of these is that which

[1] "Zur Theorie des Auerlichtes," by W. Nernst and E. Bose (*Physikalische Zeitschrift*, 1900, i. 289).
"Theory of the Incandescent Mantle," by A. H. White, H. Russell and A. F. Traver (*Journal Gas Lighting*), lxxvii. p. 879, and lxxix. p. 892).
"Theory of the Incandescent Mantle," by A. H. White and A. F. Traver (*Journ. Soc. Chem. Industry*, 1902, xxi. p. 1012).
"The Conditions Determinative of Chemical Change and of Electrical Conduction in Gases and on the Phenomena of Luminosity," by Prof. H. E. Armstrong, F.R.S. (*The Chemical News*, May 23 and 30, 1902).
"The History of the Invention of Incandescent Gas Lighting," by Auer von Welsbach (*The Chemical News*, May 30, 1902, p. 254).

regards the mantle's luminosity as an ordinary high temperature effect; as showing how the phenomena are accounted for by this explanation, we may quote the view put forward by Mr. J. Swinburne (*Journal* of the Inst. Elect. Eng., vol. xxvii. p. 161). Mr. Swinburne will have nothing to do with selective emissivity, but states that "all bodies" (presumably solid bodies) "at the same temperature give out light of the same colour." The Bunsen flame, he argues, in which the mantle is immersed, is extremely hot, and the mantle's luminosity is due to its very nearly attaining this temperature. A bad radiator (such as thoria) will reach the same temperature as the flame, but as it radiates so little energy will give but little light; what light it does give, however, will be of high luminous efficiency. A good radiator (such as ceria) will radiate energy so fast that it will not attain anything like the flame's temperature. It is, therefore, only necessary to add sufficient ceria to the thoria to increase the emissivity enough to get a good quantity of radiated energy, but not enough to lower the temperature unduly, in order to get a composition giving a brilliantly luminous mantle. This explanation does not appear to us sufficient, especially when one considers that it is polished, and not white, bodies which are bad radiators, so that if it is legitimate to argue from their behaviour at low temperature, thoria would be expected to be but little inferior as a radiator to ceria or even carbon. Also there seems some reason to think that selective emission is more probably the rule than the exception (see, for example, the work of Nichols and Blaker, published in the *Physical Review*).

Le Châtelier and also Nernst (*loc. cit.*), arrive at the same final result as Mr. Swinburne—namely, that the mantle is so bright because it more nearly approaches the temperature of the flame than any other body similarly placed—but by a different argument. The experiments which they made led them to conclude that the emissivity of the mantle is poor in the region of the red rays; hence there is little energy lost in non-luminous radiations, and the mantle can in consequence come up to the high temperature of the flame, at which it begins to radiate well, especially in the region from the green to the violet. The selective emissivity of the mantle material has therefore a double effect; it increases the luminosity at a given (high) temperature, and it enables the mantle to attain a higher temperature than a black body, because the total loss of energy by radiation is diminished. Bunte, on the other hand, claims that the assumption of selective emissivity is unnecessary, and that the mantle is at a higher temperature than the flame (*Berichte* Deut. Chem. Ges., 1898, i. 5). This view is supported by experiments he performed, in which different substances were raised to incandescence in pairs in the inside of an electrically heated tube; no appreciable difference could be observed in the light given by carbon, thoria, ceria or the material of the mantles. It remains to be explained how the temperature of the mantle can be higher than that of the flame. This is due, he and Killing suggest, to the catalytic action of the ceria, which, by oscillating between a low and high state of oxidation, increases the rate of combustion at the mantle surface and so raises its temperature. The thoria is necessary, according to Killing, to give a large surface over which the ceria molecules are spread: and Bunte suggests that it also acts as an insulator between the ceria molecules, enabling them to maintain the high temperature that their catalytic action produces.

Obviously, the simplest method of testing the accuracy of some of these different hypotheses is to measure the temperatures of mantles of different composition. An attempt to do this has been made quite recently by Messrs. White, Russell and Traver (*loc. cit.*). The temperatures were measured by means of small thermocouples, and (by making measurements with couples of different sizes and so obtaining data for extrapolation) they claim to have arrived at a method giving with considerable certainty the temperatures of flame and mantle. Even if the accuracy of the absolute values thus obtained be impugned, the relative results are not so subject to the same objections. These experimenters find that the temperature of the mantles and flame is from 1500° C. to 1700° C.; that the mantle is at a slightly lower temperature than the flame and at very nearly the same temperature whatever its composition; and, especially, that a pure thoria mantle is at a slightly higher temperature than one of thoria and ceria. Some actual results illustrating these points may be quoted from their paper:—

Composition of Mantle. Per cent.	Temperature of Mantle. C.	Temperature of flame. C.	Candle-power per sq. in.
100 thoria	1560°	1630°	3·8
99·5 thoria & 0·5 ceria	1520°	1630°	34·0

The mantles used are said to have been identical in every respect except in their chemical composition. The differences in temperature are not very great, but, such as they are, they do not harmonise with the theory of le Châtelier and Nernst, since they show the thoria mantle to be the hotter; at the same time, they support this theory as against that of Bunte by showing the mantle to be at a lower temperature than the flame. The results also support the views of Mr. Swinburne, which require that the order of the temperature should be the same as that observed. In some other experiments, the results were less conclusive, the illumination varying from 2·5 to 48 candles with practically no temperature difference. Mantles with a high percentage of ceria were not tested. The authors themselves conclude that the illumination is to a greater degree a specific function of the material than it is of the temperature, and that the particular thoria-ceria mixture is a solid solution capable of transforming the heat of the flame into light more economically than any other substance yet known.

If this explanation is to be accepted, the mechanism by which this transformation is effected remains to be explained. In that part of the paper by Prof. H. E. Armstrong (*loc. cit.*) which deals with the question of luminosity, we find a suggestion as to what this mechanism is. Prof. Armstrong's paper is of a comprehensive and far-reaching character, dealing with many things besides luminosity in general and that of the mantle in particular, but it is only its bearing on these questions that we can consider here. Prof. Armstrong thinks that "luminosity and line-spectra are the expressions—the visible signs—of the changes attending the formation of molecules from their atoms, or, speaking generally, *that they are consequences of chemical changes*." Applying this to the Welsbach mantle, after referring to Bunte's hypothesis, he says, "this undoubtedly must be the case; but I would go further, and regard *the chemical changes* occurring at the surface as the direct seat, or origin as it were, of the luminosity. Probably a higher oxide is alternately decomposed and reformed—in other words, *the process is one of oscillatory or recurrent oxidation*." This process, then, gives direct birth to the luminous radiations and accounts for the high efficiency of incandescent oxides generally, such as the lime and zirconia light and the Nernst glower. A somewhat similar conclusion is arrived at by Dr. Auer von Welsbach (*loc. cit.*), who considers that the ceria when in one or other state of oxidation can form a compound with the thoria: hence "if reduction takes place, there is also decomposition, and if oxidation, there is recombination of these elements; these reactions may go on several million times a second, and molecular shocks are produced which give rise to luminous oscillations of the ether, and

the body becomes incandescent." Both Prof. Armstrong and Dr. Welsbach attribute the importance of the special composition of the mantle to this particular mixture forming a solid solution of a dilution favourable to the occurrence of the oscillatory changes.

We have endeavoured to put forward a summary, of necessity brief, of some of the principal theories which have been advanced to account for the luminosity of the mantle. Although it is true that some of these theories, if regarded as individually sufficient to account for the phenomena, lead to conclusions mutually inconsistent, yet there is no reason why they should not all contain some part of the truth, unless the experiments of Messrs. White, Russell and Traver be considered as sufficiently conclusive against the idea of the mantle being hotter than the flame. Such a result does not preclude the possibility of catalytic action, for the additional energy thereby developed may be all dissipated in luminous radiations. It seems that the most satisfactory explanation that the present experimental data justify is that the high luminosity is due to a combination of the good radiating power, the high temperature and the selective emissivity of the mantle. The first accounts for the high candle-power at the temperature attained; the second, which is due partly to the selective emissivity diminishing the useless radiation losses and partly, no doubt, to the catalytic action of the ceria molecules, is responsible for the high luminous efficiency of the light, so far as this is a function of the temperature; whilst the third, most probably due to the recurrent chemical changes, accounts for the high luminous efficiency so far as it is a function of the material. Thus all these causes, operating together and assisting one another, combine to produce one of the most efficient artificial illuminants that the ingenuity of man has devised.

MAURICE SOLOMON.

THE EXPLANATION OF A REMARKABLE CASE OF GEOGRAPHICAL DISTRIBUTION AMONG FISHES.

MOST text-books and papers discussing geographical distribution have made much of the range of a genus of small fishes, somewhat resembling trout, the Galaxias, commonly described as true fresh-water forms, which have long been known from the extreme south of South America, New Zealand, Tasmania and Southern Australia. The discovery, within the last few years, of a species of the same genus in fresh water near Cape Town, whence it had previously been described as a loach by F. de Castelnau, has added to the interest, and has been adduced as a further argument in support of the former existence of an Antarctic continent. In alluding to this discovery when discussing the distribution of African fresh-water fishes in the introduction to my work "Les Poissons du Bassin du Congo," in 1901, I observed that, contrary to the prevailing notion, all species of Galaxias are not confined to fresh water and that the fact of some living both in the sea and in rivers suffices to explain the curious distribution of the genus; pointing out that in all probability these fishes were formerly more widely distributed in the seas south of the tropic of Capricorn and that certain species, adapting themselves entirely to fresh-water life, have become localised at the distant points where they are now known to exist. Although as recently as October last the distinguished American ichthyologist D. S. Jordan wrote (*Science*, xiv. p. 20) "We know nothing of the power of Galaxias to survive submergence in salt water, if carried in a marine current," it is an established fact, ascertained some years ago by F. E. Clarke in New Zealand and by R. Vallentin in the Falkland Islands, that *Galaxias attenuatus* lives also in the sea. In New Zealand, it periodically descends to the sea, where it spawns, from January to March, and returns from March to May. In accordance with these marine habits, this species has a much wider range than any of the others, being known from Chili, Patagonia, Tierra del Fuego, the Falkland Islands, New Zealand, Tasmania and Southern Australia.

I now wish to draw attention to a communication made by Captain F. W. Hutton in the last number of the *Transactions* of the New Zealand Institute (xxxiv. p. 198), "On a Marine Galaxias from the Auckland Islands." This fish, named *Galaxias bollansi*, was taken out of the mouth of a specimen of *Merganser australis* during the collecting excursion to the southern islands of New Zealand made in January, 1901, by His Excellency the Earl of Ranfurly.

It is hoped that by giving greater publicity to these discoveries, the family Galaxiidæ will no longer be included among those strictly confined to fresh waters and that students of the geographical distribution of animals will be furnished with a clue to a problem that has so often been discussed on insufficient data. As observed by Jordan (*l.c.*), "all anomalies in distribution cease to be such when the facts necessary to understand them are at our hand."

Of the fresh-water species of Galaxias, eight are known from New Zealand and the neighbouring islands, seven from New South Wales, three or four from South Australia, one from West Australia, two from Tasmania, seven from South America, from Chili southwards, and one from the Cape of Good Hope.

G. A. BOULENGER.

LOCAL MAGNETIC FOCUS IN HEBRIDES.

IN the course of a recent survey in the Hebrides, Captain A. Mostyn Field, in H.M.S. *Research*, found and examined an area in the entrance of East

FIG. 1.—Examination in 1902 by H.M.S. *Research* of an area of magnetic disturbance in East Loch Roag, Lewis.
Lines of equal disturbance westerly from the norma declination shown in continuous line.
Lines of equal disturbance easterly from the normal declination shown in broken line.
Normal declination 22° W.
The figures express degrees and decimal parts.
Depth of water over area from 15 to 17 fathoms.

Loch Roag, Lewis, where there is considerable local magnetic disturbance. A plan showing the deviation from the normal declination of the compass needle at

different positions in the area is here given, and will probably be of interest. Unfortunately, no special magnetic instruments were on board, and therefore no observations on the dip or force could be made. It is hoped to complete the observations later. The maximum deviation is 11° W.

The remarkable point in this instance is not only the magnitude of the disturbing force, the depth of water and therefore the distance of the compass from the bottom being 100 feet, but that the north point of the needle is repelled from the apparent line of magnetic disturbance, and not attracted towards it as is usually the case in northern latitudes. W. J. L. WHARTON.

Admiralty, November 15.

THE NEEDS OF KING'S COLLEGE, LONDON.

A PUBLIC meeting was held on Wednesday, November 19, under the presidency of Lord Selborne, to assist the appeal being made to secure the adequate endowment and equipment of King's College, London. Many men prominent in every department of human learning were present, among whom may be mentioned the Bishops of London and Rochester, Lord Glenesk, Sir A. W. Rücker, F.R.S., Sir John Wolfe Barry, F.R.S., Sir Philip Magnus, Sir W. H. Preece, F.R.S., Mr. A. Siemens, Profs. Jeffrey Bell, W. G. Adams, F.R.S., J. M. Thomson, F.R.S., W. D. Halliburton, F.R.S., W. H. Hudson and D. S. Capper.

The following message from the King was read by the Bishop of London:—

"His Majesty is thoroughly in sympathy with the proposal to raise by subscription a large fund for the endowment of King's College as a constituent of the newly-developed University of London, and wishes the movement for that purpose all success."

The Prime Minister also sent a letter in support of the appeal. He remarked, in the course of the letter, that "It would be a serious misfortune to the interests of higher education in the metropolis if, through the burden of debt and the want of proper endowment, King's College was not able to do its part in the great work which I trust lies before the reconstituted University. Higher education cannot be made self-supporting, and is, nevertheless, one of the greatest of our national needs."

Lord Selborne, in explaining the objects of the meeting, referred in high terms of praise to the work accomplished in the past by King's College in training men adequately to undertake a noble part in the civilisation and humanisation of the world. During the course of his remarks, he referred to the value of science in the following words, which we quote from the *Times* report:—

They were met to try to help King's College to go on in the future preaching the gospel of learning and of work, the gospel of research and applied science on which the real strength of the Empire was built. Was it a great thing that King's College, with its history and distinctive features, should appeal to them for that endowment which was absolutely necessary? That effort was only part of a great movement through which they were passing at this moment. There was a fresh wave of enthusiasm for university teaching sweeping over the land. In London, in the provinces, there were movements for the extension of universities, for the founding of universities, for the development of higher education. Why? He thought it was because there was a general belief that in the university teaching of this country men were taught what they wanted to know by men who knew how to teach. They felt that the higher part of education was not lost sight of in these universities, certainly not in King's College.

It was unanimously resolved, on the motion of Sir R. Jebb,

"That, in view of the distinguished services which have been rendered by King's College to higher education and research in London, it is of the highest importance that the work of the College, in its new connection with the University of London, should receive support adequate for its effective continuance and progress."

In seconding the resolution, Sir J. W. Barry said:—

It was necessary to bring before all interested in the wellbeing of the University of London the absolute necessity of the cultivation of science and the promotion of research. They knew the story of the exultant professor who said he was investigating a subject which could not be of any use to anybody, and that was why he was so much interested in it. But that was probably only a partial view of that professor, as experience showed that researches which appeared to be of no practical use often turned out to be most valuable adjuncts to human knowledge. What was wanted was not merely to educate workmen in a technical way, but to educate masters and directors. There was no longer a possibility of the great manufactures of this country being conducted successfully without scientific knowledge from top to bottom of the whole of the people engaged.

A resolution proposed by the Bishop of London and seconded by Sir Douglas Fox pledged the meeting to use every effort to raise a sum sufficient to secure "the liberation of the College from debt, the maintenance of the efficiency of the College in laboratories and equipment for higher teaching and research, and the adequate endowment of its professorships."

NOTES.

IT is with deep regret that we announce the death of Sir William Roberts-Austen, K.C.B., F.R.S., on Saturday last, at the age of fifty-nine.

THE Academy of Natural Sciences of Philadelphia has, on the recommendation of its special committee, consisting of Messrs. Theo. D. Rand, Amos P. Brown, R. A. F. Penrose, jun., and H. F. Osborn, has conferred the gold medal of the Hayden memorial geological award for 1902 on Sir Archibald Geikie, F.R.S.

THE trawling vessel s.s. *Huxley*, which has been chartered and fitted out by the Marine Biological Association for service in connection with the International North Sea Investigations, will be alongside Fish Wharf, Billingsgate (by London Bridge) during the afternoon of Tuesday next, December 2. The president of the Association has issued invitations to an inaugural inspection of the vessel to be held on that day.

A NEW building to accommodate the French Academy of Medicine was opened on Tuesday, M. Loubet and M. Chaumié, Minister of Education, being among the guests present. Dr. A. Riche, president of the Academy, gave an address upon the history of the Academy and the contributions made to medical science by its members. "The Academy is happy," he is reported by the *Times* correspondent to have said, "to take possession of a dwelling worthy of France, which it owes to the liberality of the Government of the Republic, and whereby it obtains the means of better serving the interests of the public health."

THE formation of a British committee to take part in the movement for the erection of a memorial statue of the late Prof. Virchow at Berlin was referred to a fortnight ago (p. 35). The inaugural meeting of the committee was held on Friday last, when Lord Lister, who was in the chair, described the origin of the movement and the ready support that has been given to it. A general committee has been formed containing nearly one hundred names of men distinguished by their work in various branches of natural science and medicine; and a form of appeal

has been decided upon. At Friday's meeting, Lord Lister was appointed chairman of the memorial committee; Lord Avebury hon. treasurer; and Sir Felix Semon hon. secretary. It is to be hoped that the response to the appeal for subscriptions will be prompt and generous, so that Great Britain may take a worthy share in the erection of a monument to a man whose genius was used to benefit the whole world. Contributions should be sent to "the Hon. Treasurer of the Virchow Memorial, care of Messrs. Robarts, Lubbock, and Co., 15 Lombard Street, London, E.C.," who will send an acknowledgment to the individual contributors. When the list has been closed, the hon. treasurer will forward the amount to the treasurer of the Berlin committee, together with a list of the contributors, but the amount of the individual contributions will not be stated. All who appreciate Virchow's services to science and humanity should, therefore, not hesitate to pay their tribute to the memory of one of the greatest men of our time.

THE Liverpool correspondent of the Central News states that the Nobel prize of 3000*l*. for researches in connection with malaria will be a personal one to Major Ross, principal of the Liverpool School of Tropical Medicine. According to the Stockholm correspondent of the *Daily Chronicle*, the prize for medicine will be awarded to Prof. Finsen, the Danish discoverer of the treatment by red light for lupus, and the prize for physics to Prof. S. A. Arrhenius.

THE directors of the Ben Nevis Observatories intimated, in a memorandum dated June, 1902, that the observatories at the top of Ben Nevis and in Fort-William were to be discontinued at the beginning of October, 1902. But, in consequence of a proposal by the Treasury to make an inquiry into the administration of the grant to the Meteorological Council, it was widely felt that an effort should be made to keep the observatories at work until the inquiry had been completed. The directors are now able to state that they have succeeded in obtaining the necessary funds, and that there will be no stoppage of the work at the observatories until October, 1904; that is, the work will go on as hitherto for at least two more years. One generous donor is to provide the whole funds necessary for the second year. This prolongation will give ample time to make such arrangements as may be consequent on the report of the committee of inquiry.

A VIOLENT shock of earthquake is reported to have occurred during the night of November 20 at Oued Marsa, in Algeria.

DR. GILBERT T. MORGAN has succeeded Prof. W. P. Wynne, F.R.S., as editor of the *Journal* of the Chemical Society.

THE inaugural address prepared by Mr. J. Swinburne, president of the Institution of Electrical Engineers, will be delivered at an extra meeting, to be held on Thursday, December 4. Mr. Swinburne's illness prevented the address from being read at the meeting of the Institution on November 13.

OWING, it is supposed, to a defect in the heating apparatus, a fire broke out at midnight of November 18 in the Zoological Gardens at Amsterdam. The outbreak started in the birds' gallery, the centre of which is occupied by rare apes. Fortunately, the loss of life was not great, though Keetje, the popular female orang-utan, was suffocated.

LORD EDMOND FITZMAURICE, M.P., chairman of the Wilts County Council, at the last meeting of the Council made a statement with regard to his negotiations with Sir Edmund Antrobus respecting Stonehenge. Though nothing has yet been definitely decided upon, Lord Edmond expects to be able to place before the Council, in February next, a scheme to arrange satisfactorily for the future of Stonehenge.

PROF. GUIDO CORA informs us that a severe snowfall has occurred in several parts of Piedmont. At Costigliole d'Asti, during the morning of November 19, the snow attained a height of a foot (30 cm.) in the most exposed spots. Another fall of snow took place on November 20-21. During the nights, the temperature has been very severe, and in the morning of November 23, at 8 a.m., the thermometer reached $-7°$ C., an extraordinarily low temperature for such a season. In Alessandria and Ivrea, also on November 19, the fall of snow was 20 cm. and 30 cm. thick.

A CREMATORIUM, established by the London Crematorium Company (Limited), was opened at Golder's Green, Hendon, on November 22, when an address was given by Sir Henry Thompson. The crematorium at Woking is too far from London to be of much use to the metropolis, but it is hoped that the institution now available, being within five miles of the Marble Arch, will do much to supply a real deficiency.

THE *Athenaeum* announces that the Vienna Academy of Sciences is making the necessary preparations for a fifth expedition out of the funds placed at its disposal by the Treitzsche Stiftung. It is to start in January, 1903, under the leadership of Hofrat Franz Steindacher, the director of the Vienna Natural History Museum. Dr. Pentor, of the same institution, will accompany the expedition as entomologist, and Othmar Reiser, the director of the Bosnian Museum at Sarajevo, as ornithologist. The expedition will land at Paranagua, in Brazil, and thence proceed to the study of the fauna of the hitherto unexplored districts of Piauhy and Maranhao.

A CORRESPONDENT writes:—"A semi-official announcement in the *Transvaal Leader* of October 23 records the formation of a regularly constituted Department of Agriculture in the Transvaal, with Mr. F. B. Smith, the recently appointed agricultural adviser to Lord Milner, as director. Forestry will be represented on the staff by Mr. Chas. E. Legat, of Edinburgh University, from the Cape Forestry Department; fruit by Mr. Davis, late manager of Mr Rhodes's fruit farms; and poultry by Mr. Bourlay, from England. A veterinary branch has been created, but the appointment of principal veterinary surgeon has not been filled. The *Agricultural Journal* was taken in hand some little time back, Mr. Burton being editor. The appointment of a forester has not been made a moment too soon, for he must select a suitable place and set about establishing a Government nursery of fruit and forest trees on the lines of the Government nurseries at Tokai, near Cape Town, where special attention is paid to the propagation of the splendid indigenous timber trees of South Africa. It is much better to plant stretches of veldt with wattles and gums than not to plant them at all; but where these grow, yellow-wood, laurel, assegai, Cape ash and white pear will also grow, than which there is no better timber for cabinet and waggon work. Afforestation should go hand in hand with irrigation in conserving the rainfall of the country."

IN the opening address which Sir William Preece delivered at the Society of Arts on November 19 (published in the *Journal* of the Society for November 21), he showed that the commercial conduct of industrial processes arising from the practical application of discoveries follows distinct laws, which may be said to constitute a science of business. Selecting the industries of water, gas, railways and telegraphs, a series of diagrams was given to exhibit graphically the comparative rates of growth of capital, revenue and expenditure. Several directions in which advance is necessary if Great Britain is to compete successfully with other progressive nations were mentioned. In the course of his address, Sir William Preece said:—"The Germans have an admirable Intelligence Department all over the world. If

any electric development is foreshadowed or suggested in any one of our colonies, especially those in which my firm acts as consulting engineer, we at once receive intimation of the fact from Germany and often from America. We never once have received similar information from any British source! I have endeavoured, to the best of my ability, on every occasion to point out that the retardation in commercial progress in the United Kingdom is not due so much to want of scientific education in the men as in the masters. It is the masters who have allowed the Americans and the Germans to oust them out of their own markets, not by any superiority in the quality of their goods, but by lower prices, by superior knowledge of the demands of the markets, by the establishment of new markets, by better direct communication with foreign countries, by superior methods of business ways, by establishing regular intelligence departments, and, above all, by possessing and exercising superior commercial technical knowledge. There is a science in business as in manufacture. We want our business men to be technically educated. Their brains must be trained as the Germans have been trained—to guide their business habits by language, observation, generalisation and common sense. They must lay aside the habits of their fathers. It is very satisfactory to find our new Universities establishing commercial faculties."

WE have received from Mr. G. G. Davis, director of the Meteorological Service of the Argentine Republic, vol. xiv. (1901) of the *Anales* (xi + 520 large quarto pages). At the time of the last published organisation report (1897), the system embraced 156 stations of various classes, including a few in Paraguay; six stations are provided with self-recording instruments of the most approved patterns, and the observations are all taken and reduced with much care. At four of the principal observing stations, elaborate discussions of the climate, under each element, are published in the volume in question, and form a very valuable contribution to the meteorology of South America.

WE learn from the Report on the administration of the Meteorological Department of the Government of India in 1901–2 that at the end of the year the total number of observatories was 235, of which 186 were maintained by the Government. Seven only were of the first class, furnished with automatic instruments for continuous records of the various meteorological elements. Rainfall was observed at 2389 stations, and seismological observations were satisfactorily recorded by means of Milne's self-registering instrument at three stations; the curves of the latter have been forwarded to the Earthquake Investigation Committee of the British Association. The movements of the upper clouds by means of photogrammeters have already been published for Allahabad; similar observations have recently been made at Simla, and the results are ready for publication. The important work of collection of observations from ships' logs has been continued with much activity at Bombay and Calcutta, and the results are utilised in the preparation of pilot charts, giving month by month the normal meteorological conditions over the Indian seas. These seas were remarkably free from severe storms during the year ending March 31, 1902, there being only seven disturbances, of which four were of slight intensity; due warning was given in all cases to the ports concerned.

THE most recent addition to the valuable series of wind charts published and in preparation by the Meteorological Office shows the mean direction and force of winds round those parts of the coasts of South America which lie south of the equator ("Wind Charts for the Coastal Regions of South America," Meteorological Office Official Publications, No. 159). The coastal regions are broken up into areas from two to five degrees "square," and in each is shown a wind rose, represented by arrows which fly with the winds and show the frequency of the winds by their length, and the force by their thickness. The charts embody the results of 264,639 observations of wind, the numbers ranging from 20,033 for September to 24,072 for January. In addition to the wind roses, mean isobars are given for the same areas. The atlas forms an advance part of the series of charts for the South Atlantic Ocean and the eastern margin of the South Pacific Ocean, in course of preparation under the direction of Commander Campbell Hepworth. Maps of this kind furnish material to the investigator as well as to the navigator which is absolutely inaccessible elsewhere. As illustrating the unique value of such charts, the light thrown on the distribution of cyclonic winter rainfall far up the east coast of South America may be mentioned, a distribution which no charts of mean pressure would account for. We look forward with the more interest to the completed charts of the South Atlantic, inasmuch as they will give a still more extended opportunity of studying the external relations and internal eeonomy of an oceanic area of low mean pressure.

WE have received from Messrs. J. W. Gray and Son a pamphlet on scientific protection against lightning, written by Mr. A. Hands. The writer gives a careful explanation of the principles which must be observed in erecting lightning conductors; as the pamphlet is written in non-technical language, it is to be hoped it may be the means of disseminating information amongst the public, since there are few subjects on which more ignorance and superstition exist. The importance of careful protection may be gathered from the fact that Mr. Hands estimates the damage caused annually by lightning in this country alone at from 50,000*l.* to 100,000*l.*

THE *Engineering Magazine* for November contains an interesting review of wireless telegraphy from the pen of Mr. A. F. Collins. The writer gives a brief historical *résumé* and explains the theoretical basis of the subject, and then proceeds to a detailed examination of the different systems of Hertzian telegraphy which have been developed in the past few years. Those who have attempted to follow the development know that the number of workers has been large and that each has evolved a system having certain distinctive features, and they will welcome an account which describes and illustrates the peculiarities of each. Mr. Collins describes the systems worked out by Mr. Marconi in England, Messrs. Slaby and Arco and Braun in Germany, Messrs. Popoff and Ducretet in France, Messrs. Fessenden and de Forest in America, Senor Severa in Spain, and the repeating system tried by M. Guarini in Belgium.

Die Zeitschrift für das gesammte Brauwesen publishes a highly interesting notice, by Dr. Klöcker, of Prof. Emil Chr. Hansen, written on the occasion of the celebration of the twenty-five years' connection of the eminent investigator with Carlsberg. Hansen's early years shadowed nothing of the career which he ultimately carved out for himself in the scientific world; indeed, a talent for portrait painting led him to migrate from his home at Ribe to Copenhagen with the intention of studying art. Here, however, he worked hard at science, and after passing his examinations at the Polytechnik, he devoted his ability and indomitable energy to botanical studies, and in 1876 he obtained the gold medal of the University for his treatise on Danish manure-moulds. In 1879, he was appointed director of the physiological department of the Carlsberg Laboratory, founded by the enlightened brewer, J. C. Jacobsen. Hansen's work on yeasts has made his name known in every quarter of the globe, and his methods and discoveries have inaugurated a new era in the history of brewing. In the new Fermentation Institute opened about two years ago, of which Hansen is director, neither money nor skill has been spared to supply him

and his able assistants, Drs. Kocker and Schiönning, with very possible facility for carrying on researches which have rendered Carlsberg so famous. The scientific world, indeed, is apt to forget, dazzled by the renown of the laboratory, that a successful brewery exists at Carlsberg which originally called into existence and supplied the wherewithal for the equipment and conduct of Hansen's Institute.

THE firms of Heraeus, of Hanau, and Dr. Siebert and Kühn, of Cassel, have undertaken the commercial manufacture of flasks, &c., from quartz. The quartz is melted in an oxyhydrogen furnace, and worked and blown to the desired shape. At present, the cost of these quartz vessels is somewhat high, but if their use becomes at all general, it is hoped that it will be possible to considerably reduce it. The accompanying photograph, taken from the *Zeitschrift für Elektrochemie* of November 13, shows one of the vessels made by these firms; it will be seen that the art of turning out such finished work as in glass blowing has not yet been attained. We recently pointed out some of the

valuable properties that quartz vessels possess, in a note on a paper by Mr. Hutton on the fusion of quartz in the electric furnace; we do not know whether Mr. Hutton's process has been taken up as yet with a view to its commercial use. It is a matter for regret that this new and possibly very important industry is apparently to be added to those which our manufacturers at home lack either the ability or energy to tackle with success.

FROM the Report of the Medical Officer of Health for the City of London, we gather that a commendable sanitary supervision is being exercised within the City area. A detailed inspection of kitchens of restaurants, &c., was commenced early in the year. With regard to tuberculosis, the Medical Officer says:—"Although probably not the most important, there can be little doubt as to the causal effect of tuberculous meat and milk," and 24 samples of milk were examined by Dr. Klein for the presence of the tubercle bacillus, but with negative results. During 1901, of 392 samples of milk analysed, 21·2 per cent. were found to be adulterated; but of 30 samples of milk taken from the churns on their arrival at the railway stations from the country, all were of excellent quality, showing that it is the City dealer who is the delinquent.

We have received from the author, Dr. R. von Wettstein, a copy of an essay on neo-Lamarckism and its relation to Darwinism, published in the *Sitzungsberichte* of the German Association of Naturalists and Artists.

The whole of parts iii. and iv. of the *Bulletin* of the Society of Naturalists of Moscow is devoted to an elaborate and profusely illustrated memoir, by Monsieur N. K. Koltzoff, on the development of the skull of the lamprey, *Petromyzon planeri*, in relation to the doctrine of the segmentation of the vertebrate head. It is concluded that the lampreys and their immediate relatives are descended from an ancestral form—the hypothetical Octotrema—furnished with eight pairs of gill-slits. This, in turn, was derived from an earlier form with a still larger number of slits.

To the issue of *La Belgique Coloniale* of November 9, Dr. Forsyth Major contributes some important notes on the okapi skins and skeleton received from the Congo Free State in Belgium, and placed at his disposal for description. The specimens appear to demonstrate that there are two forms of okapi, distinguishable from one another by size, colour, the striping on the legs and the proportions of the skull. For the one represented by the Belgian examples, the author suggests the name *Ocapia lebrechtsi*, in honour of the Secretary of the Interior for Belgium. This form is now definitely known to be horned in the male and hornless in the female; but the author does not at present consider himself justified in stating that the same condition obtains in the form represented by the mounted hornless skin in the Natural History Museum.

IN a paper published in the *Bulletin* of the American Museum (vol. xvi. art. 25), Dr. J. E. Duerden emphasises the importance of boring algas in the disintegration of corals. "Nearly every fragment of dead coral in the West Indies is marked by a number of green specks, indicating the tunnels of an alga, and these in time lead to the breaking up of the whole mass." The author is inclined to believe that boring algas have more to do with the formation of lagoons in coral islands than has the solution of the coral-substance by the carbonic acid contained in the water. "It is just in such quiet spots as lagoons that the various boring algæ would be expected to grow most favourably, and by their incessant ramifications lead to the ultimate disintegration of any block of coral, following it even when reduced to fragments." Nevertheless, it is not to be assumed that this is by any means the sole agency in lagoon-formation.

THE whole of parts i. to iii. of vol. xxvi. of *Notes* from the Leyden Museum is occupied by an important paper on the fresh-water fishes of Borneo, by Prof. L. Vaillant, of the Paris Museum. It appears that the expedition recently dispatched to Borneo by the Society for the Encouragement of the Scientific Exploration of the Dutch Colonies succeeded in ascending a river on one side of the island and descending by another on the opposite side, thus effecting a complete traverse. In spite of many difficulties, a large collection of fresh-water fishes was made, which includes a number of new species. The importance of the collection lies, however, in the proof afforded, that the fresh-water fish-fauna of Borneo differs essentially from that of Celebes—notably in the presence of carps (Cyprinidæ) and cat-fishes (Siluridæ), which are totally wanting in the latter island. It is incidentally mentioned that the fresh-water fishes of Palawan and Balabac are intermediate between those of Borneo and the Philippines, with a preponderance of Bornean types.

THE publications in a European language of the Earthquake Investigation Committee of Japan have now reached their eleventh number. This last issue, which is by Dr. F. Ōmori,

treats of the macro-seismic measurements made in Tokio between September, 1887, and July, 1889. These measurements, which are given in tabular forms, refer to the periods, amplitudes, directions and durations of different earthquakes. One map shows the origins of the earthquakes which were felt in Tokio, many of which are within a radius of 30 miles from that city, whilst all, with the exception of two or three, originated at a distance of not more than 75 miles. A second map shows the distribution of origins of earthquakes which were not felt in Tokio. The distance of these from that town approximately vary between 10 and 130 miles. These various origins may be divided into zones. One of them, which is suboceanic, runs parallel with the eastern coast line. The remainder are inland, and practically run from the backbone of the country at right angles to the Pacific coast.

AMONG the recently published memoirs of the Geological Survey are two relating to the coal-fields of North Staffordshire and South Wales. Both are explanatory of the new series Geological Survey maps. "The Geology of the Country around Stoke-upon-Trent," by Mr. Walcot Gibson and Mr. C. B. Wedd, is accompanied by two editions of the map, sheet 123, one with and one without the drift deposits, and both are colour-printed. This is a distinct improvement on the old hand-coloured maps, and the execution by the Ordnance Survey leaves nothing to be desired. The price also (1*s.* 6*d.*) is very moderate. The memoir contains a concise account of the Pottery Coal-field, and it will be noticed that the higher portions of the Coal-measures, previously regarded as Permian, are now subdivided and represented on the maps. The recognition of their true position has a very important bearing on further explorations for coal in the northern-midland area. The Triassic and superficial deposits are described, and there is a chapter on economic and applied geology. "The Geology of the South Wales Coal-field, part iii., the Country around Cardiff," is by Mr. A. Strahan and Mr. T. C. Cantrill. It is likewise an explanation of the geological map, sheet 263, which at present has been issued only in the hand-coloured form. The area described is just outside the limits of the great coal-field, but it includes the bordering rocks of Lower Carboniferous and Old Red Sandstone, and a little area of Silurian rocks by the Rhymney River. It also takes in a small portion of Somerset, near Weston-super-Mare. Resting irregularly on the older formations are the Keuper conglomerates and marls, the Rhætic beds and the Lower Lias. A particular description is given of the Rhætic beds, as they first received recognition by the Geological Survey in the conspicuous headland of Penarth. The Glacial and post-Glacial deposits, the water-supply and economic products receive due attention, and there is a full bibliography of geological books and papers relating to the South Wales Coal-field.

THE Irish gold ornaments which a few years ago were acquired by the British Museum have been the source of much departmental correspondence and opposed opinions, the excitement being due to the fact that these valuable and interesting specimens are lodged in the British Museum rather than in the Irish National Museum in Dublin. One argument for their retention in London was that, although they were found in Irish soil, there was no proof that they were of Irish manufacture. In the current number of the *Journal* of the Royal Society of Antiquaries of Ireland (part iii. vol. xxxii. p. 211), there is a paper by Mr. R. Cochrane which conclusively proves that these are genuine Irish objects, and Mr. Cochrane concludes that these *ex voto* objects, especially the golden boat, were connected with St. Columba's voyage to Drumceat, in A.D. 575 or 596, when he was accompanied by the Scottish King Aedan, and their deliverance from the dangers of shipwreck may have furnished the *motif*. There is a note substantially to the same effect, by the Rev. J. M'Keefry, in the same *Journal* (p. 266). Mr. Cochrane's paper is illustrated by a map and several illustrations borrowed from Mr. Arthur J. Evans's paper "On a Votive Deposit of Gold Objects found on the North-west Coast of Ireland" (*Archaeologia*, vol. lv. p. 391).

THE first part (pp. 424, figs. 412) of a new "Lehrbuch der vergleichenden Anatomie," by Prof. B. Haller, of the University of Heidelberg, has just been published by the house of Gustav Fischer, Jena. The work will be reviewed when it has been completed.

THE September issue of *Himmel und Erde* contains a very readable article, from the pen of Dr. H. Wagner, on natural colouring matters. Many interesting facts concerning the early history of these colouring matters are detailed, and the successful attempts at the replacement of several of these by synthetic products are described. In another article, by Herr Kürchhoff, an account is given of the trials which have been made with turbines as motive power on ships.

A FOURTH edition, revised and enlarged, of Prof. R. C. Carpenter's book on "Heating and Ventilating Buildings" has recently been published. In the review of the first edition of the work, in our issue for February 27, 1896, the author was congratulated on producing a really good book on a subject seldom treated scientifically. It is gratifying to find that the book has met with the success it deserves. In its revised form, it should continue to be used largely by heating engineers and architects. The book is published in this country by Messrs. Chapman and Hall, Ltd.

THE little book edited by Prof. Perry, F.R.S., containing an account of the discussion on the teaching of mathematics which took place at the Glasgow meeting of the British Association in 1901, has reached a second edition. The book is enlarged by the addition of the Report of the British Association Committee upon the Teaching of Elementary Mathematics (drawn up by the chairman, Prof. Forsyth, F.R.S.) which was presented at the Belfast meeting this year, and of the letter addressed to this committee by twenty-two mathematical masters in public schools. The book is published by Messrs. Macmillan and Co., Ltd., at 2*s.* net.

THE first part of a new volume (the third) of the "International Catalogue of Scientific Literature" has been published. The subject is "Physiology, Including Pharmacology and Experimental Pathology," and the second part of the volume referring to it will be issued shortly. The publication of the physiology volume in two parts has been considered advisable, instead of waiting until all the material for the year 1901 has been collected, but in future years, when the organisation of the work has been fully developed, the volume on physiology will be issued as one publication each year. The general scheme of the "International Catalogue" may be judged from the notices of the two volumes on botany and chemistry in NATURE of July 3 and September 4 (vol. lxvi. pp. 217 and 436). The first annual issue will consist of thirteen complete volumes and four volumes made up of two parts each. Three instalments have now been published, and of the remainder of the issue four are announced as in the press and fourteen in preparation. The price of the complete issue is 18*l.*

THE products of the decomposition of normal cupric acetate under the influence of heat have been frequently investigated, but no perfectly definite results have been obtained. Messrs. Harcourt and Angel, as the result of a very careful research, have found that the decomposition products are acetic acid, water, cuprous acetate, carbon dioxide, carbon monoxide and a residue containing copper, carbon and small quantities of oxygen and hydrogen. A trace of acetone is also obtained as a result of the decomposition.

SOME interesting facts concerning the velocity of crystallisation have been found as the result of an investigation by Dr. von Pickardt, published in the current number of the *Zeitschrift fur physikalische Chemie*. The velocity of crystallisation of super-cooled benzophenone is diminished to the same extent when equimolecular quantities of the most various substances are dissolved in it. The diminution of the velocity for any one dissolved body is, moreover, not proportional to its concentration, but to the square root of this. The regularities which have been observed may be utilised in a practical way for the determination of the molecular weights of substances dissolved in the crystallising medium.

A NEW fortnightly journal—the *Biochemisches Centralblatt*—is to make its appearance very shortly. The editor is Dr. Carl Oppenheimer, and the directors of the undertaking are all men well known for their contributions to biochemistry. It is not intended that the new journal shall serve as a medium for the publication of original papers; its chief object will be to give an abstract of all papers dealing with biochemical subjects published in other journals. The only original contributions which will find a place in the *Centralblatt* will be reviews of the condition and progress of small specialised branches of the subject, and it is proposed that each fortnightly issue shall contain such a *résumé*. The first number will appear early in December. The publishers are Gebrüder Borntraeger, Dessauer Strasse 29, Berlin S.W., and the yearly subscription is 30 marks.

THE examination of the electrical conductivity of a large number of substances dissolved in liquid hydrocyanic acid by Messrs. Kahlenberg and Schlundt (*Journal of Physical Chemistry*, October, 1902) has shown that while some salts are not such good conductors as their corresponding aqueous solutions, others conduct much better. Solutions of acids in liquid hydrocyanic acid are generally much poorer conductors than aqueous solutions, and the authors conclude that electrolytic conducting power is essentially determined by the specific nature of the compound formed when solute and solvent act on each other to form the solution. Certain chemical changes which have been investigated in hydrocyanic acid solution present remarkable peculiarities. It is found, for instance, that whereas trichloracetic acid readily attacks metallic magnesium and sodium carbonate, it has no action on zinc or calcium carbonate.

THE question of the influence of moisture on the combination of hydrogen and chlorine has been advanced another stage by the recent experiments of Messrs. Mellor and Russell. Great precautions were taken to ensure the purity of the gases used in the experiments, the hydrogen being prepared by the action of steam on metallic sodium and the product purified by absorption in palladium. Pure chlorine was obtained by the electrolysis of fused silver chloride. After the gases had been left in contact with phosphorus pentoxide for nine months in the dark, it was found that a small spark at once caused a violent explosion, and complete combination took place. The mixture of dry gases could, however, be heated to 450° C. without explosion taking place, whereas a moist mixture in a similar bulb exploded at about 260° C. With the dry mixture it was further found that in sunlight no explosion takes place, but that the combination of the gases is very slow. The experiments show clearly that the presence of moisture has very considerable influence on the union of the two gases.

THE additions to the Zoological Society's Gardens during the past week include a Lesser White-nosed Monkey (*Cercopithecus petaurista*) from West Africa, presented by Mr. W. A. Filbert; a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Mr. C. A. Rawlins; a Lanner Falcon (*Falco lanarius*) from Egypt, presented by Dixon Bey; a Globose Curassow (*Crax globicera*) from Central America, presented by the Hon. Mrs. Lawly; a Stone Curlew (*Œdicnemus scolopax*) European, presented by Mr. A. W. Arrowsmith; eight Dwarf Chameleons (*Chamaeleon pumilus*) from South Africa, presented by Miss Kay; a Horned Lizard (*Phrynosoma cornutum*) from Mexico, presented by Mr. C. W. Farquharson; seven Viperine Snakes (*Tropidonotus viperinus*) European, presented by the Rev. F. W. Haines; two Smooth-headed Capuchins (*Cebus monachus*) from South-East Brazil, a Macaque Monkey (*Macacus cynomolgus*) from India, six Mountain Witch Ground Doves (*Geotrygon cristata*) from Jamaica, two Changeable Lorikeets (*Ptilosclera versicolor*) from North-West Australia, a Suricate (*Suricata tetradactyla*) from South Africa, deposited; an English Wild Cow (*Bos taurus*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN DECEMBER:—

Dec. 1. 6h. 37m. to 10h. 19m. Transit of Jupiter's Sat. III. (Ganymede).
1. 5h. 15m. Minimum of Algol (β Persei).
4. 7h. 38m. to 8h. 33m. Moon occults β Capricorni (mag. 3·4).
5. 7h. Moon in conjunction with Jupiter. Jupiter, 5° 52′ S.
10. 7h. 8m. to 8h. 22m. Moon occults ζ^1 Piscium (mag. 4·2).
10. 20h. Venus in conjunction with Uranus. Venus, 0° 8′ S.
11–12. Epoch of Geminid meteoric shower.
13. 13h. 53m. to 14h. 56m. Moon occults δ^1 Tauri (mag. 4·0).
13. 14h. 27m. to 15h. 23m. Moon occults δ^2 Tauri (mag 4·7).
14. 16h. 52m. to 17h. 0m. Moon occults 120 Tauri (mag. 5·3).
15. Venus. Illuminated portion of disc = 0·998, of Mars = 0·904.
15. 18h. 24m. to 18h. 42m. Moon occults 26 Geminorum (mag. 5·1).
16. 3h. 34m. to 8h. 29m. Transit of Jupiter's Sat. IV. (Callisto).
16. 5h. 49m. to 6h. 32m. Moon occults λ Geminorum (mag. 3·6).
16. 12h. 27m. to 13h. 20m. Moon occults 68 Geminorum (mag. 5·0).
17. 18h. 37m. to 19h. 36m. Moon occults A^2 Cancri (mag. 5·8).
18. 10h. 9m. Minimum of Algol (β Persei).
21. 6h. 58m. Minimum of Algol (β Persei).
21. 15h. 0m. Moon in conjunction with Mars. Mars, 4° 22′ N.
22. 7h. 0m. Sun enters Capricornus. Winter commences.
30. 0h. 6m. to 3h. 49m. Transit of Jupiter's Sat. III. (Ganymede).
31. 5h. 0m. Moon in conjunction with Saturn. Saturn, 5° 20′ S.

EARLY OBSERVATIONS OF NOVA PERSEI.—In *Circular* No. 66 of the Harvard College Observatory, Prof. Pickering details the results which have been obtained from the measurement of the photographs of the region of Nova Persei which were obtained during the years 1890, 1893 and 1894.

These measurements indicate that the star on the Harvard photographs, which was pointed out by Father Zwack, of the Georgetown College Observatory, and also announced by M. S. Blakjo (*Astronomische Nachrichten*, 157, 193), is a variable which for several years has oscillated between the thirteenth and fourteenth magnitudes, and they also lead to the conclusion that it was, for that period, within one or two seconds of arc of the Nova's position, the difference in position being less than the probable errors of measurement.

COMET 1902 *c* (GRIGG).—A communication from Mr. P. Baracchi, director of the Melbourne Observatory, to No. 3828 of the *Astronomische Nachrichten* states that a search was made for this comet on the first available evening after Mr. Grigg's announcement of its discovery, but without success; nor has the comet been found by any of the Australian observatories. This may be accounted for by the prevalence of bright moonlight on the available nights and by the statement of Mr. Grigg that the object was an extremely faint one.

Enclosed with this communication is a list of the observations made by the discoverer. These observations state that the comet, when first seen, appeared as a faint nebula and was about twice the diameter of Jupiter, the atmosphere never being quite clear. Fourteen observations were made between July 23, when the comet was first seen, and August 3, but after the latter date, bad weather and bright moonlight prevented any further observations.

The instrument used was a $3\frac{1}{2}$-inch refractor, and the N.A. clock stars β, γ and δ Virginis, and ν Virginis, were observed as "near" stars, the apparent position of the last named being taken as 11h. 40m. 52s. $+ 7° 4'.5$.

From the observations made on July 24, 27 and 30, Mr. Grigg has computed the following corrected elements:—

$$T = 1902 \text{ June } 20{\cdot}33 \text{ G.M.T.}$$

$$\begin{aligned} \omega &= 301^\circ\ 46'{\cdot}1 \\ \Omega &= 217\ 31{\cdot}4 \\ i &= 16\ 42{\cdot}9 \\ \log q &= 9{\cdot}76618. \end{aligned}$$

The position for August 3 as computed from these elements differs by + 1m. 36s. and + 4′ from the observed position on that date.

The computed position at perihelion was $\alpha = 113° 34'$, $\delta = + 15° 23'$, about 10° north of Procyon, the apparent distance from the sun being 25° E., 6° S. The longitude of the comet from the sun would then increase, and the comet would pass through Cancer towards Regulus until it reached Virgo at the time of its discovery by Mr. Grigg.

APPARENT DEVIATIONS FROM NEWTON'S LAW OF GRAVITATION.—In a paper read at the Göttingen meeting of the Astronomische Gesellschaft on August 4, Herr Peter Lebedew reviewed the various theories which have ever been proposed to account for the apparent contradiction to the law of gravitation as observed in the repulsion of comets' tails from the sun, and he finally accepts the theory of Kepler, which attributes the repulsive force to solar radiation.

The author stated that he had recently confirmed the quantitative relation expressed in the formula for this repulsion, due to Maxwell and Bartoli.

For a spherical body, the diameter of which is great as compared with the wave-lengths of the solar radiation, the resulting action (F) is expressed, in gravitational units, by the formula

$$F = 1 - \frac{1}{10{,}000} \cdot \frac{1}{r\delta}$$

where r is the radius in centimetres and δ is the density of the body as compared with that of water. For dust particles, the diameters of which are comparable with the wave-lengths of the solar radiation, the above relation does not hold good.

This relation explains the varying behaviour of different parts of a comet, for it is obvious that, in a cometary nucleus made up of meteorites of various dimensions and densities, we should expect varying values of F.

TOTAL LIGHT OF ALL THE STARS.—Mr. Gavin J. Burns contributes to No. 3, vol. xvi. of the *Astrophysical Journal* an interesting account of some results he has obtained whilst attempting to estimate the total light of all the stars.

In the first place, he determined the relative brightness of different parts of the sky by observing these different parts through varying thicknesses of ordinary clear glass, and then determining what proportion of the total incident light was transmitted by a unit thickness of glass. He found that the luminosity of the Milky Way varies from two to three times the luminosity of the rest of the sky.

Secondly, he compared the luminosity of the stars with that of the normal sky by the method of putting the star image out of focus until its apparent brightness was equal to that of the surrounding sky; by this process he deduced, from the mean of several independent observations of various stars, that half a square degree of non-Galactic sky gives as much light as a fifth-magnitude star. From further observations, Mr. Burns found that, given a perfectly black background, stars as faint as the eighth magnitude would be readily visible.

WEST INDIAN VOLCANIC ERUPTIONS.

AS a panacea for much ignorance, the subtle fluid of Franklin stands next to superstition. If you cannot explain the angry workings of a volcano by a Pluto, a Vulcan or the strugglings of the damned, tell the man in the street that it is due to electricity and he is happy. At the present moment, in seventeen columns of the *Revue Scientifique* of September 6, M. Arthur Tarquin offers to the world an electrical theory of volcanic action which, to a great extent, is novel. At the outset we are told that the earth is entirely governed by the sun, and as its energy varies so will various activities on the earth vary. In establishing such a connection for volcanic activity, M. Tarquin, however, poses as a special pleader. In Tokio, for example, he says that earthquakes (*sic*) are most numerous about the times when sun-spots are at a maximum and *at a minimum*. Dr. E. Naumann, who examined the earthquake registers of Japan, however, failed to find such a connection, and others who have worked with materials relating to other countries have arrived at similar conclusions. As another example of incompleteness in statement, we are told that at the "*moment précis*" of the eruption in Martinique, with a mathematical exactitude magnetic needles at observatories throughout the world were violently disturbed. Even if we admit this to have been the case, we fail to see why similar phenomena were not observed with the more violent eruption which took place the day previously in St. Vincent.

As solar energy penetrates denser and denser layers of the earth's atmosphere, the same becomes warmer and warmer; why, therefore, asks M. Tarquin, should not the internal heat of the earth be explained by similar reasoning? This heating he apparently regards as the result of an increasing resistance to the passage of electricity. The oceans are regarded as vast accumulators. Electric potential is greater where ocean currents meet with obstacles, as, for example, where the Gulf stream passes the Antilles, and it is, therefore, in such places where volcanic activity is pronounced.

So convinced was M. Tarquin of the truth of his theory that he brought the same to the notice of M. le Ministre des Colonies, but it apparently received but small consideration. An official commission was sent to Martinique, but it neither foretold the eruption of July 9 nor that of August 27. On the contrary, it concurred in the return of the inhabitants to their deserted homes and the establishment of brigades of soldiers at Morne Rouge and other places, whilst the chief of the scientific mission issued in the official journal a letter assuring the inhabitants of safety.

This advice M. Tarquin holds to have been based on classical but false hypotheses respecting the cause of volcanic activity, and the exposition of these views lulled many into a feeling of security which they paid for with their lives. The theory of the "pyrophiles" is dangerous to humanity.

The *Revue Scientifique* of September 13 contains a report by the delegates of the Paris Academie des Sciences on the eruption in Martinique of May 8.

This first refers to a chronological account of the eruptions and various volcanic manifestations before the destruction of St. Pierre, and gives a description of the crater of Mont Pelée. By the eruption many fissures were formed, the existence of which is recognised by lines of steam vents. These continued beneath the sea, and accounted, no doubt, for the interruption of the cables and the numbers of dead fish observed on May 5. From these fumaroles steam and sulphuretted hydrogen escape, and round their orifices crystals of sulphur and sal-ammoniac are found. Their temperature at a depth of 0·10m. is about 400° C. Along the beds of the rivers Blanche and Sèche, and particularly near their mouths, these vents are very vigorous, but they vary in their activity and give rise to variations in the temperature of the water in the rivers.

The cinders which fell at Prêcheur formed a layer about 25 centimetres in thickness. At Carbet lapilli one centimetre in diameter were common. Some fragments were larger, and were

similar to those which fell at Fort de France and François on May 8 and 20. On July 9 the character of the ejectamenta became more pumiceous. Bombs 1·3m. in diameter were projected 800 metres. There does not appear to have been any change in the depth of the ocean near to St. Pierre.

On May 8 at the time of the eruption the sea at Fort de France receded 1m., and there were five or six undulations at intervals of about five minutes. Similar movements were also observed on May 20 and 26, June 6 and July 9. From May 7 to May 10 an unusually strong current was observed on the west coast. Each eruption was accompanied by a barometric oscillation from 1 to 3mm. in amount.

In *McClure's Magazine* for August, and in the *Fortnightly Review* for September, Prof. Angelo Heilprin contributes an article on "Mont Pelée in its Might."

For the first time we are told that for three months before the fatal explosion of May 8 Pelée had been rumbling, and that there had been occasional emissions of steam. The hour at which this explosion took place is fixed by the s.s. *Pouyer Quertier* and by the cable office at Fort de France at 8h. 2m. a.m., but according to the dial of the Hôpital Militaire of St. Pierre the time was 7h. 52m. a.m.

The first explosion would therefore appear to have resulted in ruin the distribution of which was quaquaversal. It might, for instance, have been produced by the explosion of a gas cloud. The latter, which left ruins with a definite orientation, may have had the character of a blast propagated in one direction.

No doubt, Prof. Heilprin concludes, there were numerous electric explosions, unmistakable evidence of which is found in perforated pottery and metal wares.

In the *Popular Science Monthly* for August, Dr. Thomas A. Jaggar gives an account of his visit to Martinique and St. Vincent. His first landing at St. Pierre was on May 21, the day after the second great eruption of Mont Pelée. Masonry had been completely destroyed, there was an absence of large volcanic fragments, and "everything was coated with a green-grey powder or sand." No sign of molten rock was found either here or in St. Vincent. At the latter island La Soufrière was ascended twice, after which Dr. Jaggar proceeded to Barbados to learn something of the dust showers which had covered that island.

At Walliabou and Richmond the same fiery blast swept down from La Soufrière as that which swept down on St. Pierre, and just as St. Pierre is buried so is Richmond buried, the ashes at the northern end of the town being 45 feet in thickness and three feet at the southern end. The masonry in the village was swept over, and 5-foot blocks of the same were blown to distances of 40 feet. On the west sea front of the Soufrière there are now vertical walls of earth in certain places 50 feet in height where before there was a village

M. M. Ballou, in his "Equatorial Africa," writing in 1892, says that "it is confidently predicted (that Mont Pelée) will one day deluge St. Pierre with ashes and lava, repeating the story of Pompeii," a prediction, Dr. Jaggar remarks, based on "well-authenticated data."

Before this last eruption, so far back as January, the lake in the crater at Pelée was warm and the odour of sulphuretted hydrogen was perceived. In April, steam was emitted and rumblings were heard. From April 24 there were actual eruptions.

In St. Vincent, local earthquakes had been on the increase for a year, and so far back as May, 1901, people were frightened away from the north-west slope of the Soufrière by rumblings and quakings. The lake bubbled and sulphurous coatings were found on the rocks. In short, the signals were so pronounced that the leeward slopes of the Soufrière were abandoned, and hence the small loss of life. Had the Governments of both islands maintained vulcanological stations, the records of "tremors, sounds, sights, smells and temperatures" would no doubt have formed an increasing series of warnings.

In the Blue-book (Cd. 1201) we find 144 official communications relating to the volcanic eruptions in St. Vincent and Martinique in May, 1902. These, as may be expected, are varied in their character. Some refer to earthquakes, others to eruptions. Many are requests for assistance, whilst others are expressions of sympathy. In communication No. 129, Mr. Secretary Chamberlain calls the attention of the Board of Trade to the bravery of Captain Freeman and suggests that it should not be allowed to pass without recognition. The reply to this states that the Board has decided to award Captain Freeman a piece of plate in recognition of his gallantry. Other communications deal with the mineralogical character of the ejectamenta, personal experiences within the devastated zone, pecuniary losses and other matters. Although many of the notes in this volume have but a small scientific value, there yet remains much not to be overlooked by those who compile the history of these terrible disasters.

Dates of Volcanic Eruptions in Central America and the West Indies (Rockstroh-Fuchs).

West Indian eruptions are marked ×.
Unusual seismic disturbances are marked —.

From the above, which is chiefly compiled from the writings of Rockstroh and Fuchs, it will be noticed that *all* the West Indian eruptions have been accompanied by unusual seismic disturbances either in the West Indies themselves or in neighbouring rock folds.

J. MILNE.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—In consequence of the large number of students in the department of anatomy, it is proposed to appoint two additional demonstrators, to be paid from the fees received for instruction.

The State Medicine Syndicate report that ninety candidates have been examined by them in the present year; of these, fifty-two were successful in obtaining the University diploma in public health. The Syndicate propose that a second grant of 1000*l.* be made from the funds in their hands toward the new Medical School buildings, in which provision will be made for teaching and examinations in sanitary science.

The Sedgwick Memorial Museum of Geology is nearly ready for occupation; the building syndicate estimate the cost for structure and fittings at more than 45,000*l.* Of this, some 27,000*l.* comes from the accumulated subscriptions to the memorial fund, 3000*l.* will be obtained from the University Press profits, and the balance probably from the benefaction fund.

THE Right Hon. Sir William Hart Dyke, Bart., M.P., will distribute the prizes at the Merchant Venturers' Technical College, Bristol, on Friday, December 12.

THE *Athenaeum* announces that Sir William Muir has resigned the post of principal of the University of Edinburgh, which he has held since 1885.

IN his inaugural address at the opening of the session of the Royal College of Science, Prof. Perry expressed his anxiety for the creation of a fund to provide bursaries to assist the national scholars and other Government students. We are glad to hear that this fund has been started with a gift of 100*l.* from the Drapers' Company, to be divided equally among ten of the scholars. The Company do not pledge themselves to continue this help.

LOCAL museums and local natural history societies can be of much assistance to nature-study in schools by directing attention to observations of natural objects. We are, therefore, glad to see that there will be a conference on nature-study at the Stepney Borough Museum on December 3, at 5.30 p.m.,

when Mr. A. D. Hall, director of the Rothamsted Agricultural Experiment Station, will give an address. The chief object of the conference is the development of the work of the museum with the schools.

ABOUT six hundred teachers and school managers from all parts of the East Riding met at Beverley on Saturday last, at a conference on nature-study. Lord Herries, chairman of the Technical Education Committee of the East Riding County Council, presided, and an address was given by Prof. Miall, who advised his hearers not to use stuffed animals and dried plants in the class-room, but wherever possible to study living animals and plants. A representative committee was elected to promote nature-study in the East Riding and Hull.

WE learn from the *British Medical Journal* that the Board of Trustees of the Johns Hopkins University, Baltimore, has accepted an offer made by Dr. and Mrs. Christian Herter, of New York, to give 5000*l*. to found a memorial lectureship in the medical department of the University, "designed to promote a more intimate knowledge of the researches of foreign investigators in the realm of medical science." This end is to be secured by inviting each year some eminent worker in physiology or pathology to deliver one or more lectures at the Johns Hopkins University upon a subject with which his name is associated. The lecturer will receive as an honorarium the annual income of the endowment. The selection of the lecturer will be made by a committee consisting of Dr. Welch, Dr. Osler and Dr. Abel.

THE Gordon Memorial College at Khartoum, which Lord Kitchener opened recently, is now ready for the chemical and bacteriological research laboratories presented by Mr. Henry S. Wellcome during his recent visit to the Soudan. The fixtures and appliances, made in England, have already been shipped. The equipment for scientific work is most complete in every detail, and will be equal to that in any similar laboratories in Europe. The Sirdar has appointed as director of these research laboratories Dr. Andrew Balfour, of Edinburgh, who has done good work in bacteriology. The Soudan presents exceptional opportunities for the study of tropical diseases, especially malaria, typhoid and dysentery, and it is anticipated that the results of the investigations of Dr. Balfour and his staff will be of the greatest importance. Apart from the original researches and general sanitary work, Dr. Balfour and his staff will devote their attention to the study of the cereals, textile fibres and various matters affecting the development of the agricultural and mineral resources of the country. Dr. Balfour leaves England on December 11, and will be entertained at dinner at the Princes' Restaurant, Piccadilly, on December 8.

A POST-GRADUATE course for the training of teachers in secondary schools will be commenced in January at the London Day Training College, Clare Market, W.C. Candidates for the one year's course of professional training must be graduates, or must have undergone a course of university study and passed an examination equivalent to that for a university degree in arts or in science. All students will receive instruction in the theory, history and art of education, so as to prepare them for the examination for the teacher's diploma of the University of London, and will also go through a course of practical work in approved secondary schools. All the principles studied in the lecture room will be exemplified in the schools, and visits of observation will be made to schools of marked excellence or of special educational interest. Candidates should make application for admission to the course for graduates not later than December 8. Applications should be addressed to the Secretary of the Technical Education Board of the London County Council, 116 St. Martin's Lane, W.C.

THE report of the Indian Universities Commission, to which attention was directed in these columns on September 4, has given rise to many expressions of dissatisfaction in the native Press of India. A resolution explaining the attitude of the Governor-General in Council towards the report was recently circulated among local governments and administrations with a view to evoke full discussion, so that, before coming to a final conclusion, the Government of India may know exactly what is thought by all persons concerned in Indian education. The resolution makes it quite clear that neither the Government nor the Commission desires to initiate a policy tending to make education the monopoly of the rich. At the same time, it is pointed out that a certain minimum standard of efficiency is necessary, and this is only possible if the expenditure reaches a certain amount which entails fees that some would-be students may find it difficult to pay. The Government, however, contemplates the provision of scholarships for the more able boys and an endowment to cheapen education for poor students. The *Pioneer Mail* is of opinion that the resolution may indefinitely postpone the thorough reform of Indian university education.

ON Monday afternoon, Lord Dudley, in laying the foundation-stone of a new technical institute at Belfast, remarked that if we are to hold our own in the great war of the world, we must see that the soldiers of industry are equipped with the best training that can possibly be given. Replying to the toast of his health at a dinner on Monday evening, Lord Dudley is reported by the *Times* correspondent to have said that the scheme of technical instruction in Belfast was, he understood, incomplete in respect to the fact that it did not include opportunities of learning all that modern science had to tell about the different subjects included in its course. How this defect could be remedied was a subject for careful consideration on their part. The most obvious course would be to make their scheme culminate in the Queen's College and to link that college to their institute. The great obstacle was one of expense; but he could promise them, if they put forward a scheme of that nature, and it was sufficiently supported by local efforts, that the Irish Government would consider it carefully on its merits and bring before the Treasury its claims for assistance from the public funds.

SCIENTIFIC SERIALS.

Journal of Botany, November.—The article by Mr. H. N. Dixon on new varieties of British mosses will interest bryologists. In addition, Mr. E. S. Salmon contributes some bryological notes. The monotypic genus Osculatia instituted by De Notaris is referred to Bryum. and three species of Schwetschkea, C. Müller, are confirmed, while a fourth is assigned to Leskea.—Mr. Spencer Moore describes South African plants, collected mostly by Mr. T. Ommaney and Capt. Barrett-Hamilton, of which several species are new.—The catalogue of British Algæ compiled by Mr. A. E. Batters continues the Rhodophyceæ which began in the last number. —There is presented a brief sketch and portrait of Mr. T. Comber, who made a special study of the Diatomaceæ.

American Journal of Science, November.—Observations on the eruptions of 1902 of La Soufrière, St. Vincent, and Mont Pelée, Martinique, by E. T. Hovey. The first ascent of La Soufrière after the eruption was made on May 7, when the crater was found to be practically unchanged in diameter. The "new" crater of 1812 appears to have taken no part in the eruptions, and although there are many ancient lava beds in the island, no stream of melted lava has issued from the Soufrière during the present eruption. The paper is accompanied by two maps, showing the devastated areas on the two islands, and sixteen photographs.—On the reflection of electric waves at the free end of a parallel wire system, by H. A. Bumstead.—The Upper Permian in Western Texas, by G. H. Girty.—The reduction of vanadic acid by the action of hydrochloric acid, by F. A. Gooch and L. B. Stookey. The reduction of vanadium pentoxide to the trioxide by the action of hot concentrated hydrochloric acid has been suggested as the basis of a quantitative method for the estimation of vanadic acid, but the results of previous work have been contradictory. It is shown by the author that, by the adoption of suitable precautions, the reaction can be made nearly complete, but the method is not a suitable one for the determination of vanadic acid, except when this substance is present in very small amount.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, November 14.—Prof. S. P. Thompson, president, in the chair.—A paper on the theory of the aluminium anode, by W. W. Taylor and J. K. H. Inglis, was read by Mr. Inglis. Aluminium is very slowly acted upon by dilute sulphuric acid even at moderately high temperatures. With dilute hydrochloric acid, the action is violent, and it is found that if a little hydrochloric acid or soluble chloride be added to dilute sulphuric acid, the action is as violent as with hydrochloric acid

of the same concentration. The object of the present paper is to find an explanation of this anomalous behaviour of sulphuric acid, and of the effect produced by the addition of chloride. It has long been known that, when an aluminium electrode is employed as anode in a solution of a sulphate or sulphuric acid, there is a very great resistance offered to the current, and that this resistance is due to a film which separates the electrode from the solution. If the aluminium is the kathode, or if other acids are substituted for sulphuric acid, this great resistance does not exist. It seems probable that the two phenomena are related, and that the film is also the cause of the slow action of sulphuric acid on aluminium. The authors have attempted to establish a theory which will explain these phenomena. The influence of certain salts of potassium in various concentrations was investigated, and the authors conclude that the presence of certain ions enables a large current to pass through the cell. The reason seems to be that the film of aluminium hydroxide with which the anode is covered is permeable to certain ions but impermeable to others. The anomalous behaviour in sulphuric acid would then be due to the impermeability of the film to the SO_4'' ions and also to the $Al^{\cdots}$ ions. Further experiments gave support to the view that the abnormal behaviour of aluminium anodes in sulphuric acid is due to impermeability.—A paper on a determination of the ratio of the specific heats at constant pressure and at constant volume for air and steam was read by Mr. Mackower. The method employed in this paper is similar to that used by Lummer and Pringsheim, and consists in allowing the gas under investigation to expand adiabatically and measuring the lowering of temperature caused by such expansion. The author's value for the ratio of the two specific heats in the case of air is 1·401. The observations with steam were similar to those in the preceding experiments, but special precautions were necessary to prevent the condensation of the steam in the tubes leading to the vessel. The results for steam were not sufficiently accurate to justify the application of corrections for radiation and for conduction and convection. The values of γ deduced from two series of experiments were 1·307 and 1·304.

Royal Astronomical Society, November 14.—Dr. J. W. L. Glaisher, F.R.S., president, in the chair.—Dr. Isaac Roberts read a paper on Sir W. Herschel's nebulous regions, compared with photographs of the same regions taken simultaneously with the 20in. reflector and 5in. Cooke lens. The results show that on forty-eight of the areas described by Herschel as nebulous there is no visible trace of diffused nebulosity, while on the remaining four there is nebulosity with very characteristic features. Photographs of these remarkable nebulous regions were thrown on the screen.—Prof. H. H. Turner read a paper on the suggestion made by Sir D. Gill that the brighter stars are, as a whole, rotating with respect to the fainter stars as a whole. A comparison of photographs taken at Oxford between 1892 and 1902 indicated a relative motion of the brighter stars of about the same amount as that found by Sir D. Gill, but in the opposite direction. Prof. Turner made the suggestion that the stars nearest to the sun may be, generally speaking, intrinsically fainter than those of the Milky Way, and there would thus for some regions be a discontinuity in the law by which fainter stars are, as a whole, more distant than brighter stars.—The secretary read a paper on the same subject communicated by the Astronomer Royal. A comparison has been made between Groombridge's catalogue (1810) and the Greenwich second ten-year catalogue (1890). The results, so far obtained, could not be taken as affording evidence of the cosmical movement suggested by Sir D. Gill.—Mr. E. T. Whittaker read a paper on the general solution of Laplace's equation and of the differential equation of wave-motions, and on an undulatory explanation of gravitation. The principal result was the general solution, by means of a definite integral, of the well-known partial differential equation which is satisfied by all Newtonian potential functions. It was then shown that a definite integral of a similar type furnished the general solution of the partial differential equation which occurs in the theories of light, sound and electromagnetic waves. From relations between the two solutions thus obtained, it was shown that any disturbance which can be represented by a solution of Laplace's equation can be compounded from simple uniform undulatory disturbances, and it was suggested that this analysis might furnish the explanation of the propagation of gravity.—Photographs of Perrine's Comet, taken at Greenwich, &c., were shown on the screen. On one of the Greenwich photographs, no less than seven tails were shown, one of them a degree in length.—A paper by Dr. Max Wolf on stereoscopic pictures of Perrine's Comet was read, and the photographs exhibited.—The secretary read papers by Mr. Percival Lowell on an expedition to determine the best situation for an observatory and on a proposed standard scale of "seeing."—Mr. H. C. Plummer gave a short account of his second paper on the images formed by a parabolic mirror.—Other papers were taken as read.

Geological Society, November 5.—Prof. Charles Lapworth, F.R.S., president, in the chair.—The secretary read a communication, transmitted by the Rt. Hon. the Secretary of State for the Colonies, from Mr. H. Powell, Curator, Botanic Station, St. Vincent, to Dr. D. Morris, C.M.G., Imperial Commissioner of Agriculture for the West Indies, referring to the eruption of the Soufrière on September 3 and 4. At 3 p.m. on September 3, the corrected barometrical reading was 29·947, and the attached thermometer 85° F. Mr. Powell was informed that during the day a lot of matter was ejected over the western lip of the old crater down the Laricor or Roseau Valley to the sea. At 9.55 p.m., as seen at the Botanic Station, the eruption commenced in earnest; flashes of flame and lightning were visible over the Soufrière at intervals of twenty to thirty seconds, with frequent longer intervals. At 10.30 p.m., the corrected reading of the mercurial barometer was 30·105 and the attached thermometer 81°·5 F. From about this hour, the discharges and accompanying noises increased in frequency and severity, and at 1.30 a.m. (September 4) the Soufrière was in full eruption. From this hour to 2 a.m., the eruption was more severe than on May 7, the explosions seeming to be louder and more continuous, and the electric discharges, owing, doubtless, to its being night, immeasurably grander and more awe-inspiring. At 2 a.m., the corrected barometrical reading was 30·045 and the temperature 81° F., and at 3 a.m. the corrected reading was 30·035. The marvellous electric display was checked by a heavy shower from the east, and the roar was correspondingly lessened. From about 1.30 a.m., a cloud black as gunpowder was seen advancing southward from the Soufrière, and at 2.30 this cloud had assumed a circular form and was overhead of the Botanic Station. The discharges from this cloud and to northward were exceedingly numerous and severe, and the appearance generally was as though myriads of long, fiery serpents were darting hither and thither, and a constant crackling noise was heard, in addition to the roar of the volcano. The chief disturbances seemed to be west of the Soufrière, in the direction of Martinique; and the writer is strongly of opinion, from observations at the time, that Mont Pelée and the Soufrière were in action together, but so far no news has come from Martinique. At 3 a.m. (September 4), the discharges and roar to the west nearly subsided, and the Soufrière alone seemed in action, but more on the windward side. From 3 to 4 a.m., the eruption gradually slackened, and at the latter hour had nearly ceased. The next morning, the barometer was normal at 29·950.—A second communication (also received through the Secretary of State for the Colonies) was read, dated Grenada, September 23, from Sir R. B. Llewelyn, Governor of the Windward Islands, expressing the hope that some scientific observers might be induced to go out to the West Indies and settle there for some time, in order to accumulate information as to volcanic and kindred phenomena.—The fossil flora of the Cumberland coalfield, and the palæobotanical evidence with regard to the age of the beds, by Mr. E. A. Newell Arber. The succession of Upper Carboniferous rocks in the region in question is apparently twofold—an arenaceous series, 600 feet thick, consisting of massive sandstones alternating with shales and fireclays, overlying argillaceous and carbonaceous deposits, the latter forming the productive portion of the coalfield and containing three great coal-seams, traceable throughout the district. The Upper or Sandstone series has yielded very few plant-remains from its upper division, but from the lower division a long list of plants is given. A consideration of the palæobotanical evidence has led to a reclassification of the rocks.—Some remarks upon Mr. E. A. Newell Arber's communication: on the Clarke collection of fossil plants from New South Wales, by Dr. F. Kurtz. Agreement was expressed with Mr. Arber's identification of *Rhiptozamites Goepperti*, which was taken to be a synonym of *Noeggerathiopsis Hislopi*. *Podozamites elongatus*, however, was regarded as different from *Noeggerathiopsis Hislopi*. It was not considered that there is sufficient evidence to warrant the separation of *Otopteris ovata* from *Rhacopteris inaequilatera*, in which species it may be retained, perhaps as a variety. *Rh. inaequilatera*

has been found in the Argentine, and has been described by Geinitz as *Otopteris argentina*.—On a new boring at Caythorpe (Lincolnshire), by Mr. Henry Preston. This boring, after piercing Northampton Sands, passed through 199 feet of Upper Lias, 19 feet of Marlstone, and into the Middle Liassic Clays. With the aid of other shallow wells in the Lincolnshire Limestone, this rock is shown to have a decided dip to the west down the face of the escarpment, as though it had settled down upon the eroded surface of the Upper Liassic Clay. This settlement is probably the cause of a continuous spring flowing from the junction, and it has given rise to an underestimate of the thickness of the Upper Lias.

Linnean Society, November 6.—Prof. S. H. Vines, F.R.S., president, in the chair.—Mr. H. J. Elwes, F.R.S., gave a lecture, illustrated by a specially prepared map and lantern slides, entitled "Notes of a Natural History Journey in Chile," which he performed in the winter of 1901-02, spending five months on the trip. The lecturer confined his remarks to the country which has only recently become accessible, between Mulchen and Puerto Montt. From Buenos Ayres to Santiago is a three days' railway journey, broken by the Andine pass between Puente del Inca and Salto de Soldado, which has to be performed on mules. It was evident that the forests which cover the mountains and extend into the plain had never clothed the outer valleys, though a six hours' ride into the mountains will bring the traveller to abundant groves of the Chilian "cypress," *Libocedrus chilensis*. The most striking plant is *Puya coerulea*. The lecturer visited the beautiful gardens of the late Madame Cousino at Lota; on the hill-sides, large plantations of the Californian *Pinus insignis* are rapidly changing the aspect of the country. Nothing is more striking in the central valley of Chile tranversed by the railway than the wonderful growth of introduced trees, which oust the natives. Lombardy poplars form avenues along the country roads; European oaks, thistles and introduced conifers give the aspect of Italy rather than of South America. This region may rival California as a fruit-producing country. The Agricultural College at Santiago is excellently found, its equipment surpassing anything in England. The lecturer visited the Baths of Chillan, at an elevation of about 6000 feet, where many plants and insects were collected; here the beech forests clothe the mountains, and here also a considerable quantity of the curious orchid Chloræa was obtained with some difficulty. The long fleshy roots were deeply buried in sand and stones amid the bushes and bamboo, *Chusquea andina*; those plants sent to Kew from Concepcion are growing fairly well. At Lolco, a farm on the Bio-bio river, may alpine plants were found. From Los Arcos past Lago Alumine to the Quillen river, few birds were noted, and mammals were very scarce. The extraordinary configuration of the rocks was mentioned. Early in February, the weather broke and several wet days ensued. San Martin is described as very beautifully situated, and will probably hereafter be much resorted to by visitors. The edge of the great Patagonian pampa was reached where the river Limay issues from the Nahuel-Huapi lake; from Puerto Blest to Puerto Montt, an easy track is now available, past the shores of Lago Frio, where *Fitzroya patagonica* was noted; from this lake, a magnificent view of Tronador volcano was obtained, the glaciers of which on the west side descend to about 2000 feet near Casapanque; avalanches were constantly falling from the mountain's precipices, with a noise which gave rise to its name. Here were beech trees, and a growth of *Gunnera chilensis* on the débris brought by the glacier, which was found to be of extreme interest. Lago Todos Santos is buried in forest.

MANCHESTER.

Literary and Philosophical Society, November 18.—Mr. Charles Bailey, president, in the chair.—A paper by Mr. Lionel Adams on a contribution to our knowledge of the mole (*Talpa Europaea*) was communicated by Mr. W. E. Hoyle. The writer, who has been studying the mole for the last four years in the neighbourhood of Stafford, called attention to the singular neglect of this interesting species by naturalists since the time of Le Court (the well-known scientific mole catcher) and Geoffroy Saint-Hilaire at the beginning of the last century, the statements of these observers having been accepted by subsequent writers—with trifling exceptions—without any attempt at verification. The mole has been credited with making its "fortress" on a uniform plan, with exactly the same number of galleries and runs communicating with the nest in precisely the same way, but the writer pointed out that, though he had dissected more than 300 fortresses, he had never found two alike or a single one corresponding to the time-honoured figure in the text-books. His observations showed that the tunnels in the interior of the fortress are not contrived as a means of escape from enemies, but are merely formed incidentally in the process of excavation and in piling up the superincumbent mound. There is, however, one exception to this, viz. the "boltrun," which is a tunnel leading out of the bottom of the nest. The conclusion was also arrived at that, though the mole is not actually blind, its power of vision is extremely limited and it finds its prey by scent alone. Instances were given of the mole eating the eggs of pheasants and partridges, after having undermined the nests, a fact which had hitherto escaped notice.—Mr. F. F. Laidlaw read a paper on some new species of marine planarians from Torres Strait and the Pacific.

PARIS.

Academy of Sciences, November 17.—M. Albert Gaudry in the chair.—On the impurities in compressed oxygen, and on their effect on combustions carried out in the calorimetric bomb, by M. Berthelot. Commercial compressed oxygen appears to be made in three ways, from barium peroxide, peroxide of manganese together with an alkaline hydrate and by the electrolysis of water. Samples of gas prepared in these three ways were examined for oxides of carbon, hydrogen and hydrocarbons, with the result that the amounts of these impurities were found to be too small to have any effect on the use of the gas for calorimetric determinations, and even when used for the estimation of carbon and hydrogen no error is introduced except in the case of the oxygen prepared electrolytically, when an appreciable amount of hydrogen may be present for which a correction is necessary.—On the recent publications of the Observatory of Paris: "Stellar Catalogue," part iv.; "Photographic Catalogue," vol. i.; *Annales*, Observations of 1898; *Memoires* (23); and *Bulletin* of the International Committee (3), by M. Lœwy.—On the determination of the exact position of a mercury meniscus illuminated by a bundle of horizontal rays, by M. G. Lippmann. The difficulties of determining the exact position of a mercury surface are well known, and various devices have been suggested for overcoming them. The method suggested by the author is to illuminate the surface of the mercury by a bundle of horizontal light rays, formed by a collimator placed approximately in a line with the reading telescope. The outline of the mercury meniscus is then seen as a perfectly sharp line, and good observations can be made with a microscope furnished with a micrometer eyepiece. The extreme variation of a set of ten observations carried out in this way was 0·005 mm., with a mean error of about 0·0025 mm.—A simplification of Foucault's pendulum, by M. d'Arsonval. The form described was designed by M. Cannivel, and is noteworthy for its simplicity and cheapness.—The localisation of normal arsenic in some organs of animals and plants, by M. Armand Gautier. The author has applied the methods previously described by him to the examination of the feathers of birds, some marine and freshwater algæ, coal, sea-water and rocks. The conclusion is drawn that arsenic appears to be as widely spread as nitrogen and phosphorus. It is invariably found, although in small proportion, in primitive rocks, soil, sea-water, plants, especially in algæ, and in terrestrial and marine animals. In the latter, it is especially localised in those organs of ectodermic origin which are concerned with sensation and reproduction.—On the specific differences between the two diseases *Nagana* and *Mal de Caderas*, by MM. A. Laveran and F. Mesnil. These two diseases have many points of resemblance, but on close examination prove to be two specifically distinct diseases.—Effect of the excision of the madreporite in starfish, by M. V. Delage.—On the law of pressures in cannon, by M. E. Vallier.—On the analogy between the X-rays and the Hertzian oscillations, by M. P. Duhem.—On the recent sunset glows at Bordeaux, by M. E. Esclangon. The facts observed do not fit in with the hypothesis of cosmic dust either of terrestrial or extra-terrestrial origin. The effects produced can be better explained by the assumption of the production of finely divided ice particles in the upper regions of the atmosphere; the sudden disappearance of the phenomenon was found to correspond with a sudden rise of temperature.—On the approximate representation of functions, by M. W. Stekloff.—On the structure of finite groups, by M. E. Cartan.—On bipolar electrodes, by MM. Andre Brochet and C. L.

Barillet.—On the time constant characteristic of the disappearance of the radio-activity induced by radium in a closed space, by M. P. Curie.—On atmospheric hydrogen, by M. A. Leduc. Confirmation of the view recently expressed by Lord Rayleigh that the actual amount of hydrogen free in the atmosphere is only about one-sixth to one-eighth that given by M. Gautier.—On the oxalomolybdites, by M. Bailhache.—Some remarks on musculamine, a base derived from muscles, by M. S. Posternak. The base recently described by MM Étard and Vila, and which they isolated from the products of hydrolysis of the muscle of veal, appears from its properties and analysis to be identical with cadaverine, pentamethylenediamine, and hence is not a triamine as supposed by MM. Etard and Vila. It would, however appear to be the first example of the direct formation of cadaverine by the hydrolysis of an albuminoid by means of acids.—On the variation in the reserve hydrocarbons in the stem and root of ligneous plants, by M. Leclerc du Sablon.—*Landolphia Pierrei* considered as a source of caoutchouc, by M. Henri Hua.—The influence of organic materials on the development and anatomical structure of some phanerogams, by M. Jules Laurent. The author has shown in previous publications that certain organic materials, such as glucose, saccharose and inert sugar, form excellent food substances for green plants. These results are now extended to glycerol and humic acid.—The analogy between the Carpathians and the Alps, by M. Maurice Lugeon.—The electrolysis of metallic salts in the tissues, by M. André Poëy.—An apparatus for determining the duration of luminous impressions on the retina, by M. Maurice Dupont. The apparatus described has been applied to the determination of the duration of the persistence of images on the retina, under normal conditions and in pathological cases.—The production of sleep and of general anæsthesia by electric currents, by M. S. Leduc. The production of sleep and of general anæsthesia in animals by means of electric currents has been described in a previous paper, but the method gave rise to some pain at the commencement; by introducing into the circuit a rheostat without self-induction, and taking from three to five minutes to attain the full intensity of the current, these inconveniences can be removed.—The reproduction of an unlimited number of phonograms in wax for phonographic museums, by M. L. Azoulay.—The production of fixed colours on all kinds of leather by the use of salts of molybdenum combined with tanning materials, by M. Emm. Pozzi-Escot.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 27.

ROYAL SOCIETY, at 4.30.—Experiments on the Effect of Mineral Starvation on the Parasitism of the Uredine Fungus *Puccinia dispersa* on Species of Bromus: Prof. H. M. Ward, F.R.S.—Note upon Descending Intrinsic Spinal Tracts in the Mammalian Cord: Prof. C. S. Sherrington, F.R.S., and Dr. E. E. Laslett.—The Inter-relationship of Variola and Vaccinia: Dr. S. Monckton Copeman.—The Colour-Physiology of Higher Crustacea: F. Keeble and Dr. F. W. Gamble.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—On Electrons: Sir Oliver Lodge, F.R.S.

FRIDAY, NOVEMBER 28.

PHYSICAL SOCIETY, at 5.—A Slide-Rule for Powers of Numbers: Prof. J. Perry, F.R.S.—A Lecture Experiment to determine the Value of the Mechanical Equivalent of Heat: Prof. Callendar, F.R.S.—A Portable Capillary Electrometer: S. W. J. Smith.

MONDAY, DECEMBER 1.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Influence of Impurities on the Specific Gravity of Sulphuric Acid: Arthur Marshall.—The Interaction of Sulphurous and Nitrous Acids as affecting various Absorbents employed in Testing the Gases escaping from Vitriol Chambers: R. Forbes Carpenter and J. E. Linder.—Note on the Determination of the Strength of Sulphuric Acid: Arthur Marshall.

VICTORIA INSTITUTE, at 4.30.—The Babylonian Story of the Creation: Dr. T. G. Pinches.

SOCIETY OF ARTS, at 8.—The Future of Coal Gas and Allied Illuminants: Prof. Vivian B. Lewes.

TUESDAY, DECEMBER 2.

INSTITUTION OF CIVIL ENGINEERS, at 8.—High-Speed Electrical Generating Plant: T. H. Minshall.

ZOOLOGICAL SOCIETY, at 8.30.—Features of Animal Life in Southern Mexico: Dr. Hans Gadow, F.R.S.—On the Variation of the Elk: Dr. Einar Lönnberg.—On the Crustacea collected during the "Skeat Expedition" to the Malay Peninsula. Part II.: W. F. Lanchester.

WEDNESDAY, DECEMBER 3.

SOCIETY OF ARTS, at 8.—Some Aspects of Photographic Development: Alfred Watkins.

The Constitution of Enolic Benzoylcamphor; (2) Note on the Isomeric Benzoyl Derivatives from Isonitrosocamphor: M. O. Forster.—The Constitution of the Products of Nitration of Meta-acetoluidide: J. B. Cohen and H. D. Dakin.

AERONAUTICAL SOCIETY, at 8.—Presidential Address. Recent Aëronautical Progress: Major B. F. S. Baden-Powell.—The Contributions of Balloon Investigations to Meteorology: Dr. W. N. Shaw, F.R.S.—The Kite Equipment of the Scottish National Antarctic Expedition: John Anderson.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Extra Meeting for the Inaugural Address by the President, Mr. J. Swinburne.

FRIDAY, DECEMBER 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Erection of Steel Bridges, Sheffield Extension of the London and North-Western Railway: A. Reynolds.

CONTENTS.

THURSDAY, DECEMBER 4, 1902.

DR. NANSEN'S OCEANOGRAPHY OF THE NORTH POLAR BASIN.

The Norwegian North Polar Expedition, 1893-1896, *Scientific Results*. Edited by Fridtjof Nansen. Vol. iii. Published by the Fridtjof Nansen Fund for the Advancement of Science. Pp. xii + 428; 88 Plates. (London: Longmans, Green and Co., 1902.)

THIS volume discusses at great length the not very numerous observations on the physical conditions of the water in the Arctic Sea which were made on board the *Fram* during her memorable drift. The matter is dealt with in two memoirs, both by Dr. Nansen, the first on the oceanography of the North Polar Basin, the second on hydrometers and the surface tension of liquids. The second memoir may be considered as an appendix to the first, a great part of which also deals with methods and discusses experiments carried out after the return of the expedition.

We must, in the first place, express gratitude to Dr. Nansen for his choice of the English language as the medium by which the official account of his expedition is made public; a choice which brings at least this reward, that his volumes will find their natural place beside the magnificent record of the *Challenger* expedition.

It is natural to look at the contents of this volume from the separate points of view of methods and results. As to methods, it must be confessed that the key-note is one of regret mingled with hope. "What might have been" if the experience gained during the voyage had been available before it started is insisted upon almost too much; and we are sometimes tempted to forget, in dealing with the results, that the high degree of possible precision lay latent in the methods and was not actually attained. Dr. Nansen, indeed, loses no opportunity of disclaiming higher accuracy than his instruments as they were handled could give, and we have rarely seen a scientific man more candid in blaming himself for neglecting precautions which, after all, few specialists in his subject, if any, thought necessary at the time of his departure.

The methods most fully dealt with are those of determining the temperature and density of sea-water at various depths. Two methods of observing the temperature were usually used, one involving the use of the Pettersson insulating water-bottle and the other the reversing thermometer on Negretti and Zambra's principle. The insulating water-bottle is an apparatus which encloses at a given depth a large sample of water, partly in a central tube, partly between the members of a series of concentric outer tubes having no communication between them. It is thus apparent that before the temperature in the inner tube can change, the temperature of each of the concentric water-jackets must be changed to a greater degree. The important question is how long a time may be allowed to elapse before the temperature in the inner tube changes by an amount appreciable on the thermometer. The actual water-bottle used on the voyage was lost, and its constants could not be tested. Two other water-bottles of apparently identical construction gave on examination distinctly different results, and differences were also found when the external temperature was changed in various ways. It seems probable, however, that with one of the improved water-bottles on this principle, the constants of which have been elaborately determined before use, it may be possible to arrive at temperature readings to something approaching the hundredth of a centigrade degree; but this will be the result of applying many corrections, some of considerable magnitude. The question is not definitely settled, but it is clear at least that no error exceeding one-tenth of a centigrade degree should occur with a water-bottle of this description when skilfully handled. The peculiar virtues and failings of the Negretti and Zambra reversing thermometer are familiar to all who have had occasion to use that beautiful but capricious instrument for deep-sea work. Dr. Nansen discusses the various corrections which have to be applied, and in their case also he suggests improvements which should lead to increased precision and certainty. For the *Fram* expedition, the reversing thermometers gave readings the error of which in almost all cases could be guaranteed not to exceed $\pm 0^{\circ}\cdot 1$ C.

The determination of density received a great deal of attention, for just as Dr. Nansen believes that observations of sea-temperature should be correct to one-hundredth of a centigrade degree, so he believes that the density of sea-water should be obtained with a degree of precision sufficient to indicate a difference as small as one unit in the fifth place of decimals, when the density of distilled water is taken as unity. But in the case of density, as in that of temperature, the results of the *Fram* did not realise the desired ideal. The investigation as to why this was so occupied much time and led to the interesting study in hydrometry which forms the second paper. We cannot follow the experiments in detail, and it must suffice to say that the villain of the piece was finally exposed and found to be grease. Variations in surface tension due to observing with unwashed hands or wiping the hydrometer with a towel not above reproach led to the most distressing irregularities. It was shown that an ordinary stem-reading hydrometer could give good results if the glass was perfectly clean and the surface of the water swept free from impurities by careful brushing with a piece of clean paper. But better results can be obtained by using hydrometers of total immersion, which act in the heart of the liquid untroubled by surface tension or capillarity. Dr. Nansen finds the best results when using a jar with vacuum jacket on the principle employed by Prof. Dewar for handling liquid air, thus preventing change of temperature by radiation. The stemless hydrometer is weighted so as just to float in the sample of sea-water the temperature of which is read by means of a very sensitive thermometer. The temperature is then raised by stirring with a tube containing warm water, and the exact temperature at which the hydrometer begins to sink is noted; a tube of cold water is then used as a stirring rod until the hydrometer begins to rise again, and thus by one or two operations the temperature at which the sample has the precise density of the weighted hydrometer can be ascertained with high precision. Other methods of determining salinity were tried on board, the

refractometer and an apparatus for measuring electrical resistance having been experimented with. Both gave fair results, but were troublesome and consequently not much used. The electrical method required the use of a standard solution of potassium chloride the resistance of which was balanced against that of the sample by means of a slide-wire Wheatstone's bridge, a telephone being used instead of a galvanometer. In the long run, the indications of the stem-reading hydrometers had to be relied on for the tables of specific gravity and salinity published in the memoir.

Samples of sea-water were brought back for chemical analysis, but they were not numerous enough to enable any definite conclusions to be drawn. So far as they went, they showed great similarity between the chemical composition of the salts in Arctic Sea water and in average ocean water, the freezing of the surface appearing to exercise very little selective action on the dissolved salts.

The observations of temperature and density are printed in full with critical remarks, and the data are utilised to throw light on the circulation of the water in the North Polar Basin, the results of other expeditions being considered simultaneously, so far as they affect the region under discussion. Dr. Nansen endeavours to arrive at the circulation of water in the sea by calculating the density *in situ* and representing this on maps and sections by isopyknals, which bear the same relation to the circulation of the sea that isobars do to the circulation of the air, and by isosteres or lines of equal specific volume. The flow of water is deviated from the direction of the density gradient, both for horizontal and vertical movement, by the rotation of the earth, and the amount of this deviation being calculated, it is possible to estimate the circulatory force of the sea due to differences of density alone, supposing that there was no wind. But the wind, acting on the surface water or even on the ice, probably has a greater influence on the movement of the water than the isopyknal gradient; hence a large part of the discussion is occupied by the consideration of the wind-drift and its rotational deviation. It is quite impossible in the limited space of a review to enter critically into the methods by which Dr. Nansen arrives at his conclusions; indeed, the only criticism we are prepared to make is that he has perhaps given too much detail, erring towards diffuseness rather than towards conciseness. However, we can give no more concise statement of the general conclusion as to the Arctic Sea than in Dr. Nansen's own words:—

"We have thus, in our discussion of the distribution of salinity and temperature in the North Polar Basin, arrived at the conclusion that there are at least four systems of currents in a vertical section from the surface to the bottom, along the route of the *Fram*, viz.,

"(1) A surface current of water with low salinity (from about 29 per mille to 32 per mille), perhaps 20m. or 30m. deep, running towards the north-west and west;

"(2) An underlying, slow current of water with a lighter salinity and a very low temperature, running in a different direction, and consisting of surface water from other parts of the Polar Sea. The absolute minimum of temperature is situated in this current, at about 50m. or 60m.;

"(3) A current of relatively warm water with salinities of from 35·1 per mille to 35·3 per mille, coming from the Gulf Stream west of Spitzbergen, and running towards the east at depths below 250m., the maximum of temperature being situated in the water of this current at depths of from 350m. to 450m.; and

"(4) An extremely slow current of colder water, filling the deepest part of the basin between 900m. or 1000m. and the bottom. This water is the heaviest water of the preceding current, which has been cooled down and has sunk towards the bottom; it has a salinity of about 35·29 per mille. It is possible that this water forms to some extent a spiral current under the preceding current, running in a similar direction."

The relation between the water of the North Polar Basin and that of the Norwegian Sea requires additional observations before it can be fully explained, and at every step of the discussion new questions are raised which future investigations must settle.

The fresh surface layer of water in the Arctic Sea is attributed by Dr. Nansen mainly to the inflow from the great rivers of Siberia. In the mass of very slightly warmer water filling the vast hollow of the central Arctic Sea below the zone of maximum temperature, there is unundoubtedly a small but distinct rise of temperature towards the bottom, and this is attributed to the influence of the internal heat of the earth.

We feel that it has been possible to give only an inadequate idea of the value and originality of this great contribution to oceanography, and we have laid stress rather on the methods than the results, because it is by the experience gained in arriving at these methods that Dr. Nansen, as Director of the International Marine Laboratory, will be able to make the physical work of the International Council for the Study of the Sea fuller and more accurate than any similar oceanographical investigation that has gone before it.

H. R. M.

ANIMAL HISTOLOGY.

Lehrbuch der vergleichenden Histologie der Tiere. By Dr. Karl Camillo Schneider. Pp. xiv+988. (Jena: Gustav Fischer, 1902.) Price 24 marks.

WE have only one serious fault to find with this book and it reflects no discredit on the author. That any book should be issued to the public in such a form that the mere operation of cutting the leaves—to say nothing of perusing the pages—involves its falling to pieces can only be characterised as a grave fault, although it is common in scientific books which are "made in Germany." Another fault usual in books hailing from the same quarter, and against which we have frequently protested, is absent in this one, for it contains an index, although not a very complete or well-arranged index. For example, we find "mehrreihiges Epithel," "mehrschichtiges Epithel," indexed, not with "Epithel" the substantive, but in the alphabetical situation of the adjective, where no one would think of looking for them. The art and science of index making has not, it must be confessed, up to the present made much progress in Germany, a fact the more remarkable since it is the country which beyond all others is a producer of books imperatively demanding efficient indices.

For the work itself as a text-book of comparative histology we have nothing but praise. The letterpress

is well written and well printed, and the illustrations are numerous and accurate, and are also beautifully reproduced. By far the majority are original, although the author has, not unwisely, availed himself of good figures by other workers, especially in the domain of vertebrate histology, which has hitherto been more completely exploited than that of Invertebrata. Such a book as this fills an important hiatus in our series of text-books, and it is to be hoped that before long we shall see an English translation. It is certainly strange, considering the importance of the subject and the necessity that so many workers must have felt to be informed regarding what is known as to the minute structure of the tissues and organs in this or that class of animals, that no effort has been made, since the work of Leydig, which was published as long ago as the middle of the last century, to furnish, on modern lines, such an account of minute structure as is ably given by Dr. Schneider in this volume. Oppel's "Vergleichende Histologie" deals, it is true, with a part of the subject, but in a different manner, giving an account, more or less historical and bibliographical, of researches which have been made into the structure of particular organs and groups of organs in Vertebrata, with occasional original observations interspered; while in the book before us we find a description of structure founded mainly on the author's own observations on certain types in each class of the animal kingdom, and merely supplemented by occasional references to the work of other authors. Both methods have their value. That of Oppel tends to produce a book which is a veritable storehouse of information on the more limited subject with which it deals, but it suffers from the disadvantage that such a work must necessarily be enormously bulky and proportionately slow in coming to completion, and as a matter of fact Oppel's book, two or three volumes of which have already been noticed in NATURE, is not only very far from that stage, but it would almost appear—from the present rate of progress—that the end would never be reached at all; whereas in the work before us we have an account of the minute structure of all classes of animals which is, so far as it goes, complete, and is not unduly large considering the vast extent of the subject.

As a matter of fact, Dr. Schneider's work is compounded of three distinct parts, each of which might very well have been published as a separate book. The first of these—under the terms "Cytology" and "Organology"—comprehends an account of the structure of the tissues and organs of animals in general, the resemblances and differences being duly noted; it is, in fact, a general minute anatomy of the animal kingdom. The third or special part, which occupies by far the largest bulk, is also purely histological, but the minute structure is dealt with class by class, beginning with Porifera and ending with Vertebrata. There is in this some unavoidable repetition of the matter contained in the first part. On the other hand, the second part—which is termed "Architektonik"—is not histological at all, but morphological. It deals with the forms of Metazoa and their mode of production, and also includes the consideration of their classification, and such questions as the formation of species and the causes of variation. All this might very well have been omitted in a work dealing with histology—that is to say, a knowledge of the subject might very well have been assumed—in which case the bulk of the volume would have been reduced to more manageable proportions. Moreover, it could have been further reduced by a great diminution of the bibliography, which, although extensive, merely amounts to a collection of titles, for the papers given in it are not specifically referred to in the text. The value of such a list is not apparent, since at best it is sure to be incomplete and could, in fact, be readily compiled more efficiently from well-known publications accessible to everyone. It will appeal to authors who do not take the trouble to search out their own references or to verify them for themselves, but adds no real scientific value to a work of this sort unless the papers quoted have a direct bearing on points treated in the book itself. There are always to be found in the compilation of such lists sins both of omission and of commission—papers of a trivial and unimportant character included, and others of considerable importance omitted altogether. A bibliography, to be of actual value to the readers of a book, must not only have a general relationship to the subject-matter of the work, but a direct specific relationship to the detailed statements and conclusions of the author. As examples of what bibliographies in works on morphology should be like, those given in Balfour's "Comparative Embryology" and in Minot's "Human Embryology" may be instanced. With such as these, which add a definite value to the works which they complete, a bibliography like that in the work under review, even although it contains 36 pages of titles, contrasts unfavourably. In most other respects, Dr. Schneider's book is to be commended as a creditable attempt to supply a want which has been long felt, but which, no doubt, the magnitude of the task has hitherto deterred others from embarking upon.

It should, however, be stated that the author's method is dogmatic rather than critical, and that in disputed and controversial questions he gives the views of the Vienna school of histologists, to which he himself belongs, without, as a rule, so much as hinting that other views are held. If this is a fault, it is one which can be easily forgiven to the author of a text-book, for at least it tends to prevent a confusion of ideas on the part of the learner, to diminish the bulk of the work, and generally to present its contents in a more readable form, and one more useful to the average student.

PHILOSOPHY AND SCIENCE.

The World and the Individual. First Series: The Four Historical Conceptions of Being. By Josiah Royce, Ph.D. Pp. xvi + 588. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1900.) Price 12*s.* 6*d.* net.

The World and the Individual. Second Series: Nature, Man, and the Moral Order. By Josiah Royce, Ph.D. Pp. xvii + 480. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1901.) Price 12*s.* 6*d.* net.

IN the first series of these remarkable Gifford lectures, Prof. Royce gives us the broad outlines of an ontology which serves as the philosophical basis for the special discussion of cosmological and ethical problems contained

in his second volume. As a contribution to the investigation of ultimate metaphysical issues, Prof. Royce's first volume, like previous works by the same writer, deserves high commendation for the frequent grace of its style and the freshness and freedom from unnecessary technicalities with which the problems are presented to the reader. Metaphysics has a bad name with the cultivated public in general on the score of aridity and unintelligibility, but there is nothing in Prof. Royce's lectures that a thoughtful man of ordinary education should find unduly difficult or repellent, and there is much that every such man must find of the highest importance. Writing from a standpoint which may roughly be described as that of Hegelian idealism, but in entire freedom from mechanical adhesion to a master, and often with marked individual originality, Prof. Royce gives us a most instructive discussion of the different senses which have, in the history of human thought, been put upon the concept of Being. We are led by consideration of the complementary errors of realism and mysticism to the definition of real existence in Kantian terms as the valid, that which accords with the conditions of a "possible experience." But validity or genuine possibility must, again, rest on a basis of actual existence as part of a real experience: hence Prof. Royce conducts us from the third, or Kantian, to his own, the fourth, definition of real existence as the completed purpose or meaning of an idea. Space forbids detailed examination of his line of argument, but there are perhaps two main positions of the writer which seem hardly satisfactory as stated. It is not made sufficiently clear how it can be an "idea," in any recognised sense of the word, which ultimately sets all selective attention to work, and generally the relation between thought and will is left in some obscurity. Thus, both in the first and second series of lectures, Prof. Royce often seems to imply the very doubtful view that voluntary attention is the same thing as a volition to attend, but he nowhere explicitly states his position on the question. A minor peculiarity in the first series, which is perhaps open to attack, is the use made of certain logical theories in criticising the Kantian conception of reality. Prof. Royce might reconsider, in the light of objections with which he is no doubt familiar, but which he nowhere meets, the view, adopted by him from the writers on symbolic logic, of the universal proposition as a negative existential judgment.

To the professed metaphysician the most important thing in the two volumes will be the supplementary essay to vol. i., in which ingenious use is made of the modern theory of infinite series, as expounded by Dedekind and others, as the basis of a defence of the conception of the Absolute as a Self against the negative dialectic of Mr. F. H. Bradley. The argument cannot be dealt with here, but one difficulty may be noted. Prof. Royce, if I understand him rightly, assumes a very direct relation between validity and actuality. He appears to take it for granted that if you can reason about an infinite series in mathematics, it must be possible for that series to be actually summed; or again, that every proposition of an infinite series of propositions which would be true if made must actually be thought by some mind. As the infinite series of such minds, according to Prof. Royce's view, in its entirety makes up the mind of God, it would seem to follow that the *infinitus intellectus Dei*, which we are assured knows all that we know, just as we know it, is like nothing so much as an infinitely extended Bradshaw's Guide without an index. Before we can adopt this view, we need, I think, a more searching investigation into the relation of mathematical truth to actual fact than Prof. Royce has supplied. Is it, after all, allowable to assume without criticism that mathematical conceptions must be the exact counterpart of actual existence?

In the second series of his lectures, Prof. Royce uses the metaphysical standpoint secured in the first volume as the basis for a striking theory of the real character of the processes which appear to our senses as the physical order. His general thesis is one which seems inevitable if we accept the premisses of idealism, that what we perceive as physical nature is a vast society of purposive and intelligent beings, which appears to us to be a dead mechanism simply because we have no direct insight into the special nature of the purposive life which animates it. In connection with this general thesis, Prof. Royce supplies an invaluable criticism of the notion of uniformity or "natural law" and a most suggestive attempt at a philosophical interpretation of the empirical facts of evolution.

The concluding essays of the series contain a striking vindication of the doctrine of moral freedom and an ingenious argument for human immortality, in a sense rather different from that commonly put on the term. I hope it is not ungracious, in the presence of such a wealth of suggestive discussion of topics of vital interest, to suggest that Prof. Royce's psychology is sometimes of a doubtful kind. More than once he seems to make the contrast between my self as it is in time and my "self in eternity," with its complete insight into the solution of the problems my temporal self finds insoluble, so sharp as to amount to a positive ascription of two distinct types of existence to the same individual. His eternal self becomes, especially in the last lecture, so much a sort of lesser god, and so remote from the struggling, perplexed creature I know as my temporal self, that it is not quite easy to see how the two can ultimately be one. His doctrine of sin, deeply true as many of his statements are felt to be, again, seems to me to involve the already mentioned confusion between attending voluntarily and willing to attend. Lastly, the argument for the temporal immortality of every self might perhaps be found hardly consistent with the admission of the temporal origination of new selves by evolution. Does not evolution involve the disappearance of selves in precisely the same sense in which it involves their origination? Prof. Royce's argument, if pressed, ought to prove immortality *ex parte ante* as well as *ex parte post*. And, in view of his general acceptance of a clarified Christianity, it is not improper to ask whether Prof. Royce agrees with all serious forms of Christian doctrine in recognising the possibility that some selves may be finally "lost," and, if so, how he interprets such ultimate loss. Misgivings of this kind, however, need in no way detract from our admiration of the courage with which Prof. Royce has essayed the task of bringing idealistic philosophy into line with the positive results of empirical science, and of the vast originality and ability with which that task has been, on the whole, executed. The Gifford trustees are indeed

to be congratulated on having been the immediate causes of the publication of three such works as the Gifford lectures of Profs. Ward, Royce and James. There have been few equally important additions to English philosophical speculation in recent years. A. E. Taylor.

THE PARALLEL RUNNING OF ALTERNATORS.

Der Parallelbetrieb von Wechselstrommaschinen. By Dr. Gustav Benischke. Pp. 55. (Brunswick: Friedrich Vieweg und Sohn, 1902.) Price M. 1.20.

The second volume of "Elektrotechnik in Einzel-Darstellungen," of which the first was mentioned in these columns some time ago, appears in the above form and fully sustains, if it does not surpass, the excellent character of the first volume. Besides the general normal parallel running of alternators, including, of course, polyphase machines, the disturbing influences which make parallel running difficult or impossible are discussed. To the mathematically inclined, the theoretical explanation of the phenomena met with in the parallel running of alternating-current machinery offers exceptional opportunity for a fine display of mathematical calculations and formulæ. Fortunately, Dr. Benischke is not so inclined, and in his preface declares that the physical explanation of the phenomena appeals more directly to one's intelligence than the mathematical, and that, in the cases under consideration, the swinging and falling out of step of alternators, the mathematical method is not much good, as it is not possible thereby to prophesy whether two machines will run in parallel or not. This is, of course, what has been found in practice, and it is now usual in the construction of alternators to so design them that means for the prevention of swinging (Le Blanc's damping rings) can be placed in position should it prove necessary. The author is to be particularly congratulated on chapters x. and xi., in which these matters are discussed, for the very clear and logical manner in which he has put them.

As an introduction, the first three chapters of the book deal with the parallel running of continuous-current machinery, and the question of motor current and division of the load between the parallel sets. With continuous-current generators, the division of the load between the machines is a question for the switchboard attendant, who simply has to regulate the exciting currents, the steam-engine governors doing the rest. With alternators, the task becomes more difficult, for not only have we the additional necessity of the machines being in synchronism one with the other, but also the proper division of the load between the generators can only be attained by concurrent adjustment of both the exciting current and the steam admission. This is due to the fact that increase of the excitation of the unloaded machine is not followed by a diminution in speed due to current flowing, followed by a greater admission of steam, as in a direct-current machine, as the alternator is kept at the same speed always, being in synchronism. The proper division of the load between the alternators becomes, therefore, largely the work of the engine-driver, acting under the instructions received from the switchboard attendant, while the latter has to see that the wattless current given by the machines is kept at a minimum by the proper regulation of the exciting currents. In accordance with German practice, the author recommends the use of an indicating wattmeter or power-factor indicator on each machine to control the power factor. This has not been the usual practice in England, as the matter can just as well be done by regulating to minimum current on the machine ammeters. To-day, recording power-factor indicators are being demanded in England; this is presumably to enable the engineer to have a check on his assistants. They are also, so far as we are aware, only for use on circuits off which synchronous substation machinery is running, where the question of power factor is of greater importance than in the case now considered.

We can now only refer to the other chapters in the book, which treat of the influence of the shape of the current and electromotive-force curves, the electrical connections for parallel running with diagrams, synchronisers, under which we did not find a description of the Lincoln synchroniser, which we think is an omission, parallel running of machines situated on the same axil, and of alternators driven by gas engines. We can warmly recommend the book to all who seek trustworthy and detailed information on this important engineering subject. C. C. G.

OUR BOOK SHELF.

Hand- und Hülfsbuch zur Ausführung physiko-chemischer Messungen. By W. Ostwald und R. Luther. Zweite Auflage. Pp. xii + 492. (Leipzig: W. Engelmann.) Price 15*s.* net.

The second edition of this well-known work will undoubtedly be welcomed by a large circle of students and teachers, the more so since for some time the first edition has been out of print. The cooperation of the original author with Dr. Luther in the production of the second edition has resulted in a considerable number of changes being made in the book; a new work is, in fact, the result. Dr. Luther's long experience as demonstrator and later as subdirector of the Physico-chemical Institute at Leipzig has made him specially fitted for this collaboration, and the value of the book is greatly enhanced by the results of his daily contact with the practical difficulties of students engaged in physico-chemical work.

In the new edition, the headings of the first fifteen chapters agree with those of the first issue. Considerable changes have, however, been made in detail by the introduction of new matter. The sixteenth chapter of the original edition is represented by five chapters in the present one, the headings of which are respectively electrical measurements, electromotive force, conductivity of electrolytes (dielectric constant), quantity of electricity and transport number and finally electrical measurement of temperature. In this portion of the book, the chief work of reconstruction has been performed. The twentieth chapter deals with chemical dynamics, and a new chapter has been added on the application of physico-chemical methods to chemical questions.

Noteworthy alterations in detail are the introduction of a number of new tables of useful data, the use of the new unit for the expression of conductivity values and the inclusion of copious references to original papers dealing with the subject-matter in hand. Special forms of apparatus and details of manipulation which cannot be included in a practical text-book of anything like modest

dimensions are thus placed within easy reach of the student.

Although so rich in material, one or two omissions might with advantage be remedied in a future edition. In the chapter on measurement of pressure, no apparatus such as the differential manometer suitable for the measurement of very small pressures is described. The methods and apparatus so frequently employed in the investigation of transition phenomena of different kinds should also find a place. Such are the use of the Bremer-Frowein tensimeter, the dilatometer, the electric transition cell, &c. Apart from these omissions, the book is undoubtedly excellent. It will be found invaluable to teacher and student alike, and should find a place in every chemical and physical laboratory. H. M. D.

London Birds and Other Sketches. By T. Digby Pigott. New and enlarged edition. Pp. xiii + 256; illustrated. (London: E. Arnold, 1902.) Price 7*s*. 6*d*.

MR. PIGOTT is of opinion that every man, especially as he grows older, ought to have a "hobby," his own being the observation of birds in their native haunts. That he has recorded the results of these observations in a manner acceptable to the public taste may be taken for granted from the fact of his book having reached a third edition. Whether, indeed, he is treating of the wood-pigeons in Kensington Gardens, of the gulls and cormorants on the ornamental water in St. James's Park, of London insects, of the bearded tit in the Norfolk fens or of the sea-birds of the Shetlands and Farne Islands, the author is equally interesting; while the exquisite frontispiece by Mr. Thorburn and the other illustrations confer an additional attraction on a very charming little volume. In several instances, as in the case of gulls essaying to perch on the trees in St. James's Park, Mr. Pigott has new facts regarding bird life to place before his readers. The statement that rooks are not likely again to build in Kensington Gardens will be read with regret by all. On the other hand, bird-lovers will learn with pleasure that the bearded tit is on the increase in the Norfolk reed-brakes. Among the most interesting chapters in the volume are those on birds nesting in the Shetlands and bird life in St. Kilda.

It is, perhaps, a pity that the author did not get some professional ornithologist to look through his proofs. Had this been done, we should not have found the kingfisher, the swift and the nightjar classed as "Passeres" (p. 253) or "Regulus" given as the name of the wren (p. 22), while the statement (p. 5) that the shrikes form a link between other passerines and the birds of prey would perhaps have been modified. R. L.

How to Buy a Camera. By H. C. Shelley. Pp. xii + 144. The "How to Buy" Series. (London: George Newnes, Ltd., 1902.) Price 1*s*. 6*d*. net.

THERE are no doubt many people who would have continued to practise photography if they had had the advice contained in this handy little volume. The amateur has been, and is now, too often led to invest his money in a camera the size and bulk of which renders it impossible for him to carry it about and use except with great inconvenience. The utility, and therefore the value, of a camera to the average photographer is gauged by its facility of erection, lightness and portability, and when these qualities are combined with good workmanship in every respect, photography becomes a pleasure. In the present book, the author gives some very sound advice to the would-be photographer, and he has not forgotten to bear in mind the different sizes of pockets which have to be considered. Chapters are devoted to each of the principal items that the photographer requires, and the author seems to have shown a very fair and impartial judgment in his suggestions as to the best or most serviceable articles to be purchased. A thorough perusal of this book will effectively help anyone who wishes to take up this delightful subject, either as a hobby or as an aid to some portion of his daily work.

Recent Advances in Science. By A. E. Ikin, B.Sc. Pp. 83. (London: Normal Correspondence College Press.) Price 1*s*. net.

ACCORDING to the preface, this book has been written mainly with the object of giving pupil teachers an opportunity of obtaining some general information on the advances made in the past ten or twelve years. Unfortunately, the author shows only a superficial knowledge of his subject, and much of the information is in consequence incorrect. A good deal of it is also out of date, some of the inventions described having long since passed out of use. It may also be objected that technical terms are used much too freely in a book intended for those having no technical knowledge. Mr. Ikin's object in providing the pupil teacher with a sort of general guide to modern scientific progress is a very laudable one, but we fear it will not be realised by the book he has written. A correct description, in non-technical language, of present-day practice in the various branches of applied science would be far more valuable than a book such as this, which is likely, we fear, to do more harm than good to its readers. M. S.

Agricultural Industry and Education in Hungary. Compiled by T. S. Dymond. Pp. 177; with 98 illustrations. (Chelmsford: John Dutton, 1902.) Price 2*s*. 6*d*. net.

THIS is an account of a visit, arranged under the auspices of the Essex Technical Instruction Committee, made by the Essex farmers' party to Hungary in May and June of this year. The tour was conducted by Mr. Dymond, the lecturer in agricultural chemistry in the Essex County Technical Laboratories at Chelmsford. It would appear from these pages that excellent results are likely to follow the opportunities then given to Essex farmers to acquaint themselves with agricultural methods in Hungary. The visitors were impressed by the good farming, the abundant grain and forage crops, the breeding of excellent horses and cattle, the organisation of agricultural industries and the complete measures taken by the State to foster agricultural improvements of every kind. One of the pleasantest pieces of reading in the volume is that describing the hearty welcome extended to the party by the Hungarian authorities and people generally. A guide book, edited by the Minister of Agriculture, containing an itinerary of the journey planned under his direction, and descriptions in English of Hungarian agriculture, was, at Vienna, presented to each visitor. The party was accompanied throughout the fortnight's journey by Mr. György, Dr. Goger and Mr. Szilassy, who, as Hungarian experts in agriculture, gave invaluable assistance.

Le Ciment Armé et ses Applications. By Marie-Auguste Morel. Pp. 158. (Paris: Masson et Cie., 1902.)

THIS book, belonging to the well-known "Aide-mémoire" series, deals briefly with structures produced by the association of cement with iron or steel, distributed in such a manner as to utilise to the fullest extent the special characteristics of each. The volume opens with a description of results obtained in this field of work by numerous French engineers. Among other matters dealt with are the principal systems of applying this plan of construction to floors, girders, arches and pillars, and the materials employed. The book concludes with a set of mathematical expressions for the forms of structure approved by engineers. The text is simplified by the hundred illustrations, which, with a few exceptions, are very clear, and the book is provided with a bibliography.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Becquerel Rays and Radio-activity.

IN your report of the meeting of the Physical Society of October 31, I find the following sentence given as having been said by me in the course of some remarks on Mr. Ridout's paper on the size of atoms, with the four words which I underline accidentally omitted.

"If the electrons, or atoms of electricity, succeeded in getting out of the atoms of matter, they proceeded with *velocities which might exceed* the velocity of light, and the body was radio-active."

The omission of those four words made it appear that I had considered the velocity of the escaping electrions to be essentially the velocity of light. In reality, the electrons may escape with velocities possibly less or possibly more than the velocity of light, but certainly not all with one definite velocity.

It is probable that the electrification of air produced by the breaking up of liquids into drops,[1] by a jet of water falling through air,[2] by water-falls,[3] by the bubbling of air through water and other liquids, and by the shaking up of liquids and gases in a bottle,[4] are all to be explained by the splashing out of electrons in consequence of violent vibrations of molecules of the liquid at surfaces of separation between liquid and gas in rapid relative motion, and at places of disruption between two portions of liquid. KELVIN.

Netherhall, Largs, Ayrshire, November 27.

[The official report of Lord Kelvin's remarks was printed as received.—EDITOR.]

The Conservation of Mass.

WITH reference to the letter from Mr. Sommerville in your present issue, may I state that, in the discussion at the Belfast Meeting of the British Association, I pointed out that the height in the scale pan at which a thing is weighed affects its apparent weight and that the change from this cause is quite within the capacity of the best balances? I also referred to the last report from Sèvres by Dr. Guillaume, who made the interesting statement that it would be certainly possible now to observe that one pair of kilogram weights side by side weighed more than they would do when resting one on the other.[5]

These small differences due to distance from the centre of the earth are, however, considerably smaller than the discrepancies obtained by Dr. Landolt, but I mentioned them as representing the kind of unexpected disturbance that might come in without discovery. C. V. BOYS.

Germs in Space.

I HAVE received the enclosed letter from Mexico with a request to forward it to you; and accordingly I do so, since I suppose it not impossible that the dust of space might contain life germs of some kind. I do not think the suggested bombardment by electric corpuscles sufficient cause, though electric repulsion might sometimes act, and it has been suspected that the earth may have a faint cometary tail; but no such action is needed to account for the existence of cosmic dust of any kind.

Whether the advent of new diseases could be thus accounted for is a possible matter for debate; and incidentally it has struck me to ask whether there can possibly be any physiological discrimination between the, so to speak, windward and leeward sides of the earth on its journey through the ether, giving the morning hours a different "feel" from the afternoon hours. The idea, I admit, is extremely improbable. OLIVER LODGE.

IT is commonly assumed (*cf. e.g.* NATURE of October 16, p. 602) that if life did not originate upon the earth, it must have come upon a meteorite. How it got on the meteorite is not explained.

It occurs to me that there is no reason why small living bodies (*e.g.* spores of bacteria) should not be floating about by themselves in space. We know from recent experiments that the cold of space would not in the least destroy their germinating power, but, on the contrary, would (I presume) preserve them in a dormant state indefinitely.

Now, why should not such bodies gradually settle down upon the earth, without any destructive friction? If this can be, the meteor hypothesis becomes wholly unnecessary. [It is the *same* hypothesis: only the meteors assumed are extra small.—O. L.]

We still have to account for the living bodies in space. Is there any way in which minute particles (as bacterial spores) could leave the earth (or any other planet)? They could be carried far up in atmospheric currents, and my friend Mr. Weinzirl has found bacteria in the mountain air of the arid parts of this country. Is it possible that electric currents (such as produce the aurora) could in some cases carry them far enough to permit them to escape into space? I do not know enough about electricity to judge of this possibility.

THEO. D. A. COCKERELL.

East Las Vegas, New Mexico, U.S.A., November 2.

The Leonid and Bielid Meteor-showers of November, 1902.

IN a letter just now received from Mr. W. H. Milligan, in Belfast, some interesting details are given of observations made in his watch for Leonids at and near the November date of the shower's recently looked for reappearance. As a cloudy state of the sky prevailed generally in England on the nights in question, the result obtained in a prolonged clear view of the sky on at least one of the two most probably predicted mornings of November 15 and 16 for the shower's reappearance, that but one true Leonid, and no sign whatever of any great abundance of the shower, was visible in a watch of 4 hours on the first of those two mornings, possesses considerable interest from the fresh support which it affords to the lately calculated conclusions of very eminent astronomers, that the meteor-stream's celestial route, instead of just crossing the earth's orbit-track, as it did in the shower's three last previous returns and in many bygone centuries, now probably falls, by the effects of planetary perturbations on its course, sufficiently far inside the earth's orbit to no longer give us the magnificent spectacle of a great star-shower.

On the mornings of November 15 and 17, only (on the last of which the sky was overcast in Belfast), could short and tolerably clear views be here obtained of the brightly moonlit sky; and that the shower was indeed feebly active on the former morning was shown by one small true Leonid's appearance at 15h. 52m., of second magnitude, shooting overhead from $134^\circ + 47\frac{1}{2}^\circ$ to $126\frac{1}{2}^\circ + 54^\circ$, about 8° in $\frac{5}{8}$ths of a second, as from a radiant point at $151^\circ + 21^\circ$, the only meteor seen in a brief half-hour of cloudless sky well watched for the Leonids from 3h. 45m. to 4h. 15m. a.m. On the night of November 16–17, no meteor at all was visible in a full hour's watch in clear sky from 11h. 45m. to 12h. 45m. From Mr. A. King, at Leicester, I have just now heard that he observed one meteor only—a Leonid—in a 25m. watch on the latter night, and that in $1\frac{1}{2}$ hours on the early morning of November 13 (the only other cloudless time at Leicester in that November period), he observed 7 meteors, not one of which was a Leonid.

The watch, this year, for Bielid meteors on November 23–24 was about equally unproductive of both periodical and ordinary meteors; for in a watch of 4 hours' duration, from 7h. to 11h. on the first of those two nights (the next night being cloudy), Mr. Milligan reports from Belfast that no Andromede at all was there observed, and in $2\frac{1}{2}$ hours of clear sky, until midnight, here, only two shooting-stars (both in the first hour, and none in the last $1\frac{1}{2}$ hour of the watch) were seen, neither of which were Andromede or Bielid meteors. In $1\frac{1}{2}$ hour on the second night, until moonrise and cloud and rain interfered at 15h., only one true Bielid meteor and two other shooting-stars were here recorded.

Regarding his long watches at Belfast for the Leonids, in their recent period, Mr. Milligan writes thus:—

"Below I give a record of the watches kept. Although the results are few, yet from the fact of having seen three meteors—

two true Leonids and one slow, "stray," spent-looking shooting-star—in the strong moonlight, I should say that had the shower been in any force I should have seen more, and that therefore it must be taken to have been weak and to have gone past us inside the earth's orbit, as it did, presumably, in the past year or two. The radiant point was not determined, but it seemed to be in the usual position."

Date, 1902.	Duration of watch (Local Time*); a.m. From h. m.	To h. m.	Number of Leonids	Other meteors	Remarks. (* Local Times about 25m. slow on Greenwich Time.)
November 13 ..	12 0	1 0	0	0	Clear horizon-belt in E. and S.; cloudy afterwards.
November 14 ...	...	...	..	...	Cloudy throughout.
November 15 ...	12 0	2 0	0	1	Clear; moonlight (2nd magnitude meteor; very slow.)
,, 15 ...	3 0	4 0	0	0	,, ,,
,, 15 ..	6 0	7 0	1	0	,, ,,
November 16 ...	12 0	5 30	...	...	Cloudy.
,, 16 ...	5 45	6 15	0	0	Clear space around Leo.
November 17 ...	...	..	...	...	Cloudy throughout.
November 18 ..	12 0	4 0	0	0	Clear.
,, 18 ...	4 0	5 0	1	0	,,
,, 18 ...	5 0	6 0	.	..	No watch kept.
November 19 ...	5 0	6 0	0	0	Clear.
	Totals ...	...	2	1	

To complete the partial record which these notes supply of the shower's apparent strength this year, at somewhat near its time of greatest brightness, it may be hoped that more favourably observed particulars of the appearance of the Leonids may reach us yet from foreign places, and it might earnestly be wished, as well, that notes of the number of shooting-stars observed may have been kept at any distant station on the globe where possibly some sensible ramification and dense clustering of cometary dust along the wake of the departing meteor-stream may have happened to produce a fairly bright and numerous display of what it now appears probable may have to be known for some time to come, if not perhaps for all coming time, as the traditionally splendid celestial spectacle of the November Leonids. A. S. HERSCHEL.

Observatory House, Slough, November 26.

Vitality and Low Temperatures.

THE remarkable results of the experiments of Prof. Macfadyen and others, on the effects of low temperatures on organic life, render it highly desirable to ascertain how long vitality can be retained under such conditions, and with liquid air now available it becomes possible to extend the inquiry for an indefinite number of years—a generation if necessary.

The fact that organisms, after having been maintained for six months at temperatures far below those at which vital activities are possible, have retained their vitality practically unimpaired, profoundly modifies the conception hitherto attached to the word "life," and if it can be shown that vitality can survive for a protracted period in these circumstances, the conclusion that it is a molecular function seems inevitable.

If such an experimental result were obtained, it would strengthen the possibility of Lord Kelvin's speculation that the origin of life on the earth may have been ultra-terrestrial, and this implies that the ultimate source would probably have to be looked for under conditions not common to, posssibly transcending, our experience. W. J. CALDER.

Stellenbosch, South Africa.

THE BRITISH ACADEMY.

AT a general meeting of the Fellows of the British Academy, held on November 19, the Right Hon. Lord Reay, G.C.S.I., president of the Institute of International Law and president of the Royal Asiatic Society, was elected first president of the Academy.

At the same meeting, the *Times* announces, the following Fellows were elected the first members of the council of the Academy:—Sir W. R. Anson, the Right Hon. James Bryce, Prof. I. Bywater, Prof. T. W. Rhys Davids, the Rev. Prof. S. R. Driver, the Rev. Principal Fairbairn, Sir C. P. Ilbert, K.C.S.I., Sir R. C. Jebb, the Rev. Prof. J. E. B. Mayor, Dr. J. A. H. Murray, Prof. H. F. Pelham, the Rev. Prof. W. W. Skeat, Sir E. Maunde Thompson, K.C.B., Dr. A. W. Ward, Prof. James Ward.

At a meeting of the council, held on November 26, Mr. I. Gollancz, Fellow of the Academy, University lecturer in English at Cambridge, was appointed secretary of the Academy.

In the report of the anniversary meeting of the Royal Society, printed elsewhere in this issue, the position taken by the Royal Society in connection with the constitution of the British Academy is described. By its action, the Society limits its sphere of activity to that of the experimental sciences, and dissociates itself from the scientific study of archæology, philology, philosophy, political economy and similar branches of knowledge. Its scope is thus to be that of the Paris Académie des Sciences—one of the five academies which constitute the Institute of France—and the British Academy will correspond very nearly to the Académie des Inscriptions et Belles-Lettres and the Académie des Sciences morales et politiques. Many men of science regret that the Royal Society has thus ceased to represent the totality of British scientific work, as it formerly did, and has limited its scope to certain branches.

ANOTHER HODGKINS GOLD MEDAL AWARDED.

IN March last, Dr. S. P. Langley, secretary of the Smithsonian Institution, appointed a committee to consider whether any discovery had been made since the award of the first Hodgkins gold medal in 1899, under the general terms of the gift, "the increase and diffusion of more exact knowledge in regard to the nature and properties of atmospheric air in connection with the welfare of man," which would render it proper that such a medal should be again awarded. This committee consisted of the following distinguished men of science:—Mr. Richard Rathbun, assistant secretary of the Smithsonian Institution, chairman; Dr. A. Graham Bell, for electricity; Dr. Ira Remsen, for chemistry; Dr. Charles D. Walcott, for geology; Prof. E. C. Pickering, for astronomy; Dr. Theodore N. Gill, for biology; Prof.

Cleveland Abbe, for meteorology; Mr. William H. Holmes, for anthropology; and Mr. S. W. Stratton, for physics.

Owing to the absence of Mr. Rathbun, Dr. Remsen served as chairman at a meeting of the committee held at the Smithsonian Institution in Washington, April 15. At this meeting, the following resolution was unanimously adopted:—

"That the committee recommend to the secretary of the Smithsonian Institution that it is desirable that one of the Hodgkins gold medals be struck, and that it be

awarded to J. J. Thomson, of Cambridge, England, for his investigations on the conductivity of gases, especially on the gases that compose the atmospheric air."

The finding of the committee being approved by the secretary, steps were at once taken to have the second Hodgkins gold medal struck, under the personal supervision of its designer, M. J. C. Chaplain, of Paris. The medal (one side of which is shown in the accompanying photographic illustration) has recently been received by the Institution, and has been dispatched to Prof. Thomson through the Department of State.

SIR WILLIAM ROBERTS-AUSTEN, K.C.B., F.R.S.

BY the death of Sir William Roberts-Austen, which occurred at his official residence in the Mint on Saturday, November 22, metallurgical science has to deplore the loss of one of its most distinguished representatives. He had been in failing health for some months past, and had suffered from one or two sharp attacks of illness during the last few years, but even his most intimate friends, until a few days before his death, were quite unprepared for the suddenness of his end.

William Chandler Roberts, as he was formerly called, was born in 1843. His father, George Roberts, was of Welsh descent, whilst his mother, Maria Louisa, belonged to the Kentish family of Chandler which intermarried with the Austens. In 1885, at the request of his uncle, the late Major Austen, J.P., of Haffenden and Camborne, in Kent, he obtained Royal license to take the name of Austen.

At the age of eighteen, he entered the Royal School of Mines with the intention of being a mining engineer, but after obtaining the associateship of the school he became, in 1865, a private assistant to the late Prof. Graham, then Master of the Mint, and was employed, at the outset, mainly on the researches in inorganic chemistry and on physical chemistry which continued to occupy Graham until the end of his days. Graham died in 1869, when the Department was reorganised in accordance with the provisions of the Coinage Act of the following year. Under that Act, the Chancellor of the Exchequer became "Master, Worker and Warden" of the Royal Mint. No salary was attached to the office, but it was provided that its duties should "be performed and exercised by his sufficient deputy." In order to provide for the efficient discharge of the scientific work devolving on the Mint, a new post—that of "chemist of the Mint"—was created, and Roberts was selected to fill it, being appointed by Treasury minute of January 7, 1870.

On the death of Mr. Horace Seymour, the late Deputy Master, in June last, Sir William Roberts-Austen was appointed to fill the office *ad interim*, or until his own official connection with the Mint should be severed by resignation. This he had intended should take effect in the spring of the coming year. It may be said, therefore, that Sir William Roberts-Austen had, at one time or other, filled every office in the Mint which a man of his order could aspire to. No more convincing testimony to the manner in which he discharged his official duties, and no more eloquent proof of how he acquitted himself under the great responsibilities of his position, could be adduced than this single fact.

Roberts-Austen was one of the most many-sided men of his time. His intellectual activity found scope for itself in many ways. He had an insatiable capacity for work and he never spared himself. Those who knew him intimately frequently remonstrated with him on the manner in which he incessantly made large drafts on his store of mental and nervous power, with no thought of repose or recuperation. It was rarely that he could be induced to pay much heed to the warnings of his friends, declaring that he found in the very variety of his avocations the relaxation and rest which they desired him at times to take. This was strikingly exemplified by the manner in which he clung, with an interest amounting to affection, to his position as professor of metallurgy in the Royal School of Mines. Roberts-Austen always cherished, as one of the most treasured memories of his life, the recollection of his early association with the Royal School of Mines. Although the Royal School of Mines is to-day incorporated with the Royal College of Science, a fusion of which Roberts-Austen entirely approved and which he loyally supported, his colleagues on the council of the school were more or less dimly conscious that deep down in his mind, "at the back of his head," as the saying goes, he was still apt to regard the school as a corporate entity with a separate existence, with all the powers, privileges and prestige which it enjoyed as a separate entity in his old Jermyn Street days. There was probably no one position he coveted more than its chair of metallurgy, and no incident in his career which gave him a greater sense of pleasure and satisfaction than his appointment, in 1880, to that chair in succession to the late Dr. Percy. The feeling with which he regarded the school is intelligible enough, for it is very human and sprang from his very affection for it. It is akin to that which leads the fond father or doting brother in his secret soul to resent the removal of the daughter or the sister to a new home. No amount of talk about "a larger potentiality for good," "enlarged sphere of activity," "greater measure of advantages," &c., however willingly and sincerely assented to, will entirely subdue and efface the feeling which in the younger and more militant masculine members of a family has been known to degenerate into a secret wish

to punch the head of him who has presumed to impose his own name on his partner.

How loyal he was to the school, how affectionately he guarded its interests and how he studied to enhance its usefulness, I, who was his colleague on the council of the Royal College of Science for upwards of nine years, desire now to bear testimony. It was the wish of his heart, had he been spared, that, after his retirement from the Mint, he might spend his remaining years, or so many of them as the regulations of the Department would have allowed him to spend, in its service. It was possible that he cherished the hope that the erection of the new buildings on the other side of Exhibition Road might have afforded him the opportunity he had long desired, that of creating and equipping a metallurgical laboratory which should be worthy of this country and of an Empire whose sons are engaged in metallurgical work in almost every part of the globe. But if this was not to be, he has at least erected a monument to himself in the record of his past achievement; in the thoroughness and fulness of his teaching; in the scientific enthusiasm with which he sought to lay bare and illumine the problems of physical metallurgy. During the two-and-twenty years he held his chair, he trained a succession of men holding important positions at home and in many parts of the world, who are grateful to him for the stimulating influence of his teaching, who will recall many acts of personal kindness and good will, and who, now that his place in the subterranean lecture-room he loved so well and in which, with all the quickening zeal of a born teacher, he had spent some of the happiest hours of his life, knows him no more, will mourn his loss as that of a dear friend, and will continue to cherish his memory and recall the many kindly traits of head and heart which characterised him.

In the outset of his career as an investigator, Roberts-Austen occupied himself with a number of minor problems in inorganic chemistry, and there is little continuity of thought or effort to be traced in much of his 'prentice work. But there is invariably the note of originality. All his life through, he was strongly attracted by what is odd, uncommon or *bizarre*. Perhaps it was the Celtic blood which ran in his veins which predisposed him to the mysticism which was undoubtedly a feature of his character. Had he lived three hundred years ago, he would have been a typical alchemist and have spent the skill and energy he showed in assaying and minting gold in vain attempts to make it. Science, however, would certainly have been the richer for his efforts, for he was a very acute observer, and although occasionally his preconceptions were liable to run away with him for a time, especially in the direction of scientific heterodoxy, he was staunchly loyal to his facts. Much of his work was influenced by his strong artistic sense and by his passionate regard for beauty of form or colour. The secrets of oriental metallurgy had a singular fascination for him. He would literally gloat over some triumph of Japanese art, and the discovery of by what kind of "pickle," or by what kind of treatment, the lustre or colour or effect on a bronze had been obtained was a delight to him as intense as if he had lighted upon a new metal. The artistic side of his nature found frequent exercise in his work at the Mint, especially in medal-striking. He occasionally chafed under the necessity of having to make use of designs for which he had no sympathy, but he had a real delight in reproducing, with the highest degree of excellence that the resources at his command permitted, artistic work which his trained judgment and fine critical insight perceived to be good and true. Indeed, this sense of "finish" and feeling for artistic excellence, amounting almost to fastidiousness, was seen, not only in his actual manipulative work and in the way in which he arranged and perfected his experimental illustration, but in the manner and form in which he put together and presented any account of his labours. His lectures at the Royal Institution were invariably illustrations of this. Perhaps no man since Tyndall's day ever handled a Friday evening discourse with more tact and skill than did Roberts-Austen. His matter was always fresh, his experiments always interesting, frequently daring and occasionally strikingly original. He never tried to be rhetorical or pretended to be eloquent, but there was a certain literary finish in his sayings, a feeling for epigram, a sense of proportion in arrangement, and, at times, a quiet, subdued touch of humour which altogether made him delightful to listen to.

Of his innate love for science and of the ardour with which he pursued her, innumerable instances might be given. I shall never forget the manner in which he burst into my room, when at South Kensington, and showed me the first fragment of the beautiful rose-coloured alloy of gold and aluminium he had obtained. His delight was so real and unaffected—his joy almost infantile—as he turned and twisted the glittering fragment to the light to illustrate the depth and wonderful brilliancy of its purple. And, too, it was characteristic of him that, as I shared his admiration, he should, unasked, have seized a letter-weight and knocked off a portion of his prize and bade me take it.

I remember, too, a similar occasion when he carried me off to see the first results of his inquiry into the diffusion of solid metals, and when he showed me the little beads of gold cupelled out of the several sections of the block of lead, which had been standing for days and weeks on a plate of the precious metal, all arranged at the proper intervals of the sections on a diagrammatic representation to actual scale of the leaden block. And I may be pardoned if I recall with satisfaction that, as a consequence of that visit, I was the humble instrument of determining, with the powers that were, the Bakerian lecture of 1896.

The Royal Society's Catalogue of Scientific Papers records that Roberts-Austen published some two dozen papers, for the most part singly, but occasionally in collaboration with Sir Norman Lockyer, Prof. Osmond and the late Dr. Alder Wright.

They practically all relate to metallurgical problems, or are connected with the scientific side of his duties as an officer of the Mint. They deal with the spectroscopic characters of alloys; the physical and chemical nature of alloys; the structure of metals; the connection between the properties of metals and the periodic law; and the nature of the hydrogen occluded by palladium and by electro-deposited iron.

In 1890, at the request of the Alloys Research Committee of the Institution of Mechanical Engineers, he began to investigate the effects of small admixture of certain elements on the mechanical and physical properties of the common metals and their alloys. Whilst engaged on that work, he devised the recording pyrometer, an instrument which has proved to be of the greatest value, not only to the investigator in pure science, but also to the practical metallurgist. The results of these investigations are embodied in reports to the Institution of Mechanical Engineers, which afford a mass of valuable information concerning the structure of metals and their alloys, and their behaviour under varying physical conditions.

It was in the domain of physical metallurgy that he specially excelled, and by his unwearied energy, by his skill and resourcefulness as an experimentalist, he has succeeded in clearing up much that was vague and imperfectly understood in that field of inquiry.

He is the author of an "Introduction to the Study of Metallurgy," which has been characterised as a masterly guide to a knowledge of the principles on which the art is based.

This bald outline of Roberts-Austen's scientific work gives, however, a very inadequate idea of his diligence as a man of science or of the influence which he exerted on the progress of science. Such work as he engaged in was, from its very nature, time-consuming, and results were only obtained slowly and laboriously. From his official position, too, and by reason of his attainments, he was constantly pressed to serve upon committees, councils and commissions, into the work of which he never failed to throw himself with characteristic ardour and self-sacrifice. In 1885, he was a member of the executive council of the Inventions Exhibition. In 1889, he served on the British executive council of the Paris Exhibition, and in 1893 on that of the Chicago Exhibition. In the former year, he received the Cross of Chevalier of the Legion of Honour.

He sat with the writer on the Treasury Committee which preceded the establishment of the National Physical Laboratory, and he was also a member of the Board of Trade Committee appointed to inquire into the deterioration of steel rails during use in railway traction.

Since 1899, he had been a member of the Explosives Committee appointed to investigate explosives for use in the Army and Navy and material for the construction of guns.

Concurrently with the services he rendered to the State as a public servant, he did his fair share of labour in the organisation of scientific work as an executive officer of various scientific societies. He joined the Chemical Society in 1866 and served on its council in 1879–81, and became a vice-president in 1895–8.

In 1875 he was elected into the Royal Society, and served as a member of council in 1890–2, and at the time of his death was a member and chairman of some of its committees. He was one of the founders of the Physical Society, of which he was also a vice-president, and was an active member of the Society of Arts, of which he was a member of council and vice-president. He was also an honorary member of the Institution of Civil Engineers, of the Institution of Mechanical Engineers and of the Institution of Mining and Metallurgy.

He was elected president of the Iron and Steel Institute in 1899, and held office until 1901.

In 1888 he was made a C.B., and received his knighthood in the order in 1899.

The University of Durham made him a D.C.L. in 1897, and a year or two later he received the honorary degree of D.Sc. from the Victoria University.

He was a frequent attendant of the meetings of the British Association, and served as one of the general secretaries of the council from 1897 to the year of his death.

His last public lecture was the James Forrest lecture on "Metallurgy in Relation to Engineering," given to the Institution of Civil Engineers on April 23. In special lectures of this kind, Roberts-Austen excelled. They cost him considerable effort, for he spared no trouble to make the occasion worthy of himself and of his subject, and he had his reward in the grateful appreciation of his auditory.

Indeed, no man discharged more faithfully, more honourably or more religiously the obligations he had incurred, or which, by virtue of his position, were thrust upon him. It may be truthfully said of him that whatsoever his hand found to do he did it with all his might.

No sketch of Roberts-Austen would be complete without some allusion to his remarkable social qualities. When at his best he was an admirable talker, bright, witty and amusing; he had a keen sense of humour and was a capital story-teller. He had a dangerous gift, however, which in his later years he was slow to make use of—he was an excellent mimic. In the old days—the days of Rankine, Lord Houghton, Clifford, Aitchison—when the "Red Lions" were wont to hold high carnival, Roberts-Austen occasionally would "let himself go" and exercise his gift to the uproarious merriment of jackals, cubs, lions and lion-kings alike. Indeed, it seemed at times that he was not quite conscious of the faculty he possessed. I have heard him, to my terror, in the course of a conversation gradually copy the tones and inflexions of a man's voice, and seen him reproduce his manner to his very face. There was absolutely no intention to be discourteous in this, and it was done so gradually and with such subtlety that the man was just as insensible of the fact as Roberts himself. I firmly believe that on such occasions the unconscious mimicry had its origin in sympathy.

Some years ago, Roberts-Austen acquired a small place at Chilworth, near Guildford, to which he would repair with Lady Roberts-Austen on all possible occasions. It never meant idleness to him, but there is no doubt that the occasional change from the atmosphere of Tower Hill to the breezy, invigorating air of a Surrey common had some effect in preserving him from the constant inroad he made upon his physical and mental energy. His social instincts made him a good neighbour, and he spent time and no inconsiderable amount of money in improving the lot of those around him. There was one side of his character of which only those who knew him well were made fully aware. It is reflected, however, in the beautifully decorated little chapel which he erected near his house for the benefit of the district, and in which he was wont to minister nearly every Sunday.

T. E. THORPE.

ANNIVERSARY MEETING OF THE ROYAL SOCIETY.

THE anniversary meeting of the Royal Society was held on Monday, December 1, when the report of the Council was presented, and the members of the Council for the ensuing year, whose names have already been given (p. 35), were elected.

The first paragraph of the report refers to the formation of the "British Academy for the Promotion of Historical, Philosophical and Philological Studies" and its incorporation by Royal Charter. The President and Council of the Society were requested by the Privy Council to give their opinion upon a petition which had been presented to the Privy Council praying that the incorporation of the studies above referred to should be "provided for in some relation to the Royal Society." The report states that in the reply the Council of the Royal Society most strongly deprecated any change in organisation being imposed upon the Society from without in order that it might include within itself the studies for which the incorporation of the British Academy is asked, being convinced that such a change would destroy the independent position which the Society now enjoys as the head, in this country, of the mathematical, experimental and natural sciences. The Privy Council subsequently invited the opinion of the Royal Society upon a memorial suggesting that it would be desirable to attempt to organise officially in one institution the several branches of knowledge. The President and Council replied that they could not consent to the Royal Society forming one department of any institution or academy such as that suggested.

The statutes governing the election of Fellows under privileged conditions, under which members of the Privy Council have hitherto been admitted, have been amended. The principal amendment provides that the Council may, once in every two years, recommend to the

Society, for election as Fellows, not more than two persons who, in their opinion, have either rendered conspicuous service to the cause of science or are such that their election would be of signal benefit to the Society.

Among other matters, reference is made in the report to work carried on under the auspices of the Society in connection with malaria, sleeping sickness, the West Indian eruptions, the National Physical Laboratory, the International Catalogue of Scientific Literature, the Royal Society's Catalogue of Scientific Papers, Indian observatories and the International Association of Academies.

In the course of his annual address, the President made the following remarks upon the need for increased facilities and encouragement for higher scientific education and research :—

The supreme value of research in pure science for the success and progress of the national industries of a country can no longer be regarded as a question open to debate, since this principle has not only been accepted in theory, but put in practice on a large scale, at a great original cost, in a neighbouring country, with the most complete success.

The Physikalisch-technische Reichsanstalt of Berlin, largely due to the scientific foresight of von Helmholtz, was instituted in recognition of the principle that all the industrial applications of science rest on the foundation of pure scientific discovery. The institute has for its main objects, (1) the conduct of pure physical research, especially in such directions as are suggested by industrial questions ; (2) the construction and supply of electrical and physical standards ; (3) the verification of instruments of precision for scientific and technical purposes.

The original cost of the institute was more than 200,000*l.*, and its yearly maintenance is not less than 17,000*l.* During the five years that it has been at work, its influence upon the science and the manufacturing interests of Germany has been most remarkable. Besides the publication of numerous memoirs of original research and of papers on technical processes, the direct results of the work of the institute upon the industries of the country have more than justified the prevision of the founders ; largely, we regret to say, to our own national loss, and to the almost complete passing to that country of the renown which was formerly ours in exact scientific measurements, and for the construction of standards and instruments of precision. So true is it, that the investment of public money in scientific research can only be compared to good seed cast into good ground, bringing forth in results a hundred-, or even a thousand-fold.

The sum voted by the Government for our own National Physical Laboratory, an institution second to none in its national importance, was the very modest one of 13,000*l.* for the buildings and equipment, and an annual grant of 4000*l.* for five years in aid of the expenses of conducting the work of the institution.

The supreme necessity in this country of a more systematic application of scientific methods, both in theory and in practice, to our manufactures and industries, which was so wisely insisted upon by the Prince of Wales on the occasion of his admission to the Fellowship of the Society and again in his address at the opening of the National Laboratory, has since been confirmed and enforced in a remarkable way by the individual testimonies of thirteen Fellows of this Society, in the evidence which they recently gave, from their own knowledge and experience, either as teachers of science or as leaders and technical advisers in manufactories or commercial undertakings, before a committee of the London Technical Board.

Their testimony was of no uncertain sound, but showed clearly that the Prince's words of warning were not unneeded, and that, indeed, our industries and commerce are not only in danger, but are actually passing into the hands of other countries, where scientific research is more directly cultivated under the fostering care of the State.

The undoubted present state of apathy of the national mind in relation to the importance of natural knowledge, and its consequent inability to recognise how entirely and without exception, in every undertaking, success must depend upon our so acting in conformity with the laws of Nature that we have her on our side, as our ally, and not working against us, may arise, conceivably, from either of two causes : from a natural want of enterprise and resourcefulness inherent in the national character, or from a system of education which, relatively to the educational training of other countries, fails to develop and strengthen the qualities of mind which are needed for an adequate appreciation of science.

The former of these two possible causes may surely be dismissed at once. We need only look back in history to see how this small northern island, by its own innate energy, has come to be supreme over vast regions on all parts of the earth's surface, and is now the head of an empire which engirths the world.

We are, therefore, left, without power of escape, to the second alternative, namely, that it is our system of higher education which is in fault, clearly through being too mediæval in spirit. In accordance with the traditions of the past, our higher national education deals with words rather than with things ; it is based too exclusively on the memory of what is known, and too little, if at all, on individual observation and reasoning.

The evidence seems clear that the present inappreciative attitude of our public men, and of the influential classes of society generally, towards scientific knowledge and methods of thought must be attributed to the too close adherence of our older Universities, and through them, of our public schools, and all other schools in the country downwards, to the traditional methods of teaching of mediæval times. The incubus of the past makes itself felt, especially in the too strict retention of educational methods in which the first importance is given to the reproduction of knowledge from memory, to the acquiring and applying of what is already known ; with little, if any, guidance and encouragement to the undergraduate student in the direction of research and of independent reasoning.

With the experience of Germany and the United States before us, the direction in which we should look for a remedy for this state of things would seem to be for both the teacher and the student to be less shackled by the hampering fetters of examinational restrictions, and so for the professor to have greater freedom as to what he shall teach, and the student greater freedom as to what line of study and research he may select as being best suited to his tastes and powers.

Into the dry bones of the present academic system of reading and examination must enter the living breath of the spirit of research, that is to say, of the individual efforts of each mind, for itself and in its own way, to seek to extend our knowledge in the direction most suited to its powers, by means of original observation and reasoning, and aided by the imagination—it may be in the field in science, of history and literature, or of art.

One way of bringing about reform in this direction would be to make individual research an indispensable condition of proceeding to degrees higher than the B.A.

In addition to the intellectual influence of a training in research upon the students themselves, the official recognition by the Universities of an original investigation of some subject, as a necessary condition of obtaining the higher academical honours, could scarcely fail to bring about in the public mind a more appreciative attitude in regard to the importance of original reasoning and discovery, and so to a better understanding of the meaning to be attached to natural science and to scientific methods.

It is obvious that with a fuller knowledge and appreciation of science on the part of the nation, a complete change of its practical attitude in respect to science and science questions would necessarily follow, for under such conditions public money would be liberally voted by the Government.

The work of this year's medallists was described as follows :—

COPLEY MEDAL.

Lord Lister, F.R.S.

The Copley Medal is awarded to Lord Lister in recognition of the value of his physiological and pathological researches in regard to their influence on the modern practice of surgery.

When in 1880 a Royal Medal was awarded to him, it was acknowledged that his researches had "not only reformed the whole art of surgery, but given a new impulse to medical science generally." The experience of another twenty years has written out that judgment in still larger letters. Lister's researches have made the world a wholly different world from what it was before.

The main result of those researches, namely, the definite proof that the suppuration of wounds, no less than putrefaction, was the work of living organisms, was not reached as a happy accident; it was the natural outcome of long-continued scientific observation and reasoning, the fruit of the labours of a well-trained scientific mind. Beginning with purely histological and physiological investigations having only an indirect relation to medicine and perhaps still less to surgery, he was gradually led, without changing his method or his mode of thought, to that which has so profoundly influenced both. His work has been a shining example of that which the Royal Society was founded to advance, the shaping of a new philosophy which is for the good of man.

RUMFORD MEDAL.

The Hon. Charles Algernon Parsons, F.R.S.

The Rumford Medal is given to the Hon. Charles Algernon Parsons for his success in the application of the steam turbine to industrial purposes, and for its recent extension to navigation.

The work of Mr. Parsons is of a kind which specially comes under the terms and conditions of the Rumford Medal, as consisting "of new inventions and contrivances by which the generation and preservation and management of heat and of light may be facilitated," and as "shall tend most to the good of mankind."

By his invention and perfection of the steam turbine, he has not only provided a prime mover of exceptional efficiency working at a high speed without vibration, but has taken a step forward which makes an epoch in the history of the application of steam to industry, and which is, probably, the greatest since the time of Watt. The success of the turbine is due to the experimental skill and inventive ability which have enabled him to overcome all difficulties, and to contrive a multitude of details without which the general idea of compound working could not have been translated into practice.

The use of the steam turbine for dynamo driving has been in operation for some time and is rapidly becoming common. Machines of 2000 horse-power and over are now being built. In accordance, however, with the conditions of the Rumford Trust, that the medal shall be awarded for work done within the previous two years, his claims to favourable consideration are based specially on the recent application of the steam turbine to marine navigation. The use of the steam turbine, as is well known, enabled the *Viper* and the *Cobra* to attain speeds hitherto unattainable. It has now been introduced within the last few years in vessels for mercantile purposes on the Clyde, and is being applied to ocean-going vessels.

ROYAL MEDAL.

Prof. Horace Lamb, F.R.S.

A Royal Medal is awarded to Prof. Horace Lamb for his investigations in mathematical physics.

Prof. Lamb has been conspicuous during the last twenty years by the extent and value of his contributions to mathematical physics. His writings have been distinguished by clearness, precision and perfection of form. His early work related to hydrodynamics, the "Treatise on the Motion of Fluids," published in 1879, being one of the first adequate accounts of the modern progress of that subject.

From 1881 to 1884, he published a series of memoirs dealing with the application of harmonic analysis to vibrational problems connected with spheres and other forms of bodies.

In these papers, subjects such as the subsidence of oscillations in viscous matter, the vibrations of spherical elastic solids, free electric vibrations and forced alternating currents were treated with full application to actual phenomena. In the memoirs on electrical motions and oscillations, he developed with remarkable completeness the application of Maxwell's electric theory in this department—including such topics as the surface-concentration of alternating currents—some years before the progress of the applications of electricity had led to independent experimental discovery of the importance of these phenomena.

In 1889–90, he published (*Proc.* Math. Soc. and *Phil. Mag.*) a number of valuable papers on the elastic deformation of plates and shells, which involved many new results, and also did much towards elucidating difficulties that had been encountered in this intricate subject.

Recent work has also included a discussion "On Reciprocal Theorems in Dynamics" (*Proc.* Math. Soc., 1888), a solution of the problem of the diffraction of a train of electric waves by a wire grating (*Proc.* Math. Soc., 1898), and memoirs on the dynamical theory of the refraction and selective absorption of light by gaseous media (*Trans.* Camb. Phil. Soc., 1899, *Proc.* Math. Soc., 1900). In the latter subject, he traversed ground in which he afterwards found that he had been, to a considerable extent, anticipated (in Danish) by L. Lorenz.

His treatise on "Hydrodynamics," 1895, 604 pp. demy octavo, is universally recognised as the standard presentation of that subject. It maintains the best traditions of the British school of mathematical physics.

ROYAL MEDAL.

Prof. Edward Albert Schäfer, F.R.S.

The other Royal Medal is conferred upon Prof. Edward Albert Schäfer for his researches into the functions and minute structure of the central nervous system, especially with regard to the motor and sensory functions of the cortex of the brain.

Prof. Schäfer has contributed to animal physiology much work in various lines of research, and his discoveries regarding the nervous system have been especially numerous, from the time of his demonstration of nerves in the disc of medusa to his late work on the relation of the cerebral cortex of the ape to the sensory functions of the skin. Altogether, his neurological researches rank among the most important of contemporary British contributions to that branch of physiology. It is, however, especially for his work upon the functions of one of the ductless glands—the supra-renal—that he has a claim to recognition as a Royal Medallist. In 1894 he, in conjunction with Dr. G. Oliver, succeeded in demonstrating the existence in the cortex of the supra-renal gland of a substance, called now *adrenalin*, which is the most powerful known stimulant to the cells of visceral and vascular muscles. The discovery has since been confirmed by numerous workers, British and foreign; the original researches were, however, so accurate and exhaustive as to leave little further to be added by any means available at present. The work incidentally revealed absence of this active principle in the diseased supra-renal glands in *Morbus Addisonii*, a malady considered invariably fatal. The investigation laid the first real basis for knowledge of the functions of the supra-renal gland. Recently Prof. Schäfer has, working on lines similar to his adrenalin research, extracted from another ductless gland, the pituitary, a substance exhibiting marked properties as a diuretic.

DAVY MEDAL.

Prof. Svante August Arrhenius.

The Davy Medal is awarded to Prof. Svante August Arrhenius for his application of the theory of dissociation to the explanation of chemical change.

It is not easy to over-estimate the importance of the service rendered to chemistry by Prof. Svante Arrhenius through the publication of his memoir, presented to the Swedish Academy of Sciences on June 6, 1883, entitled "Recherches sur la Conductibilité Galvanique des Electrolytes." As far back as 1886, Sir Oliver Lodge, in referring to the second part of Prof. Arrhenius's memoir, in the Report to the British Association of the Committee on Electrolysis, spoke of it as a distinct step towards a mathematical theory of chemistry, and went so far as to say that "the title affixed to it is 'The Chemical Theory of Electrolytes,' but it is a bigger thing than this—it really is an attempt at an *electrolytic theory of chemistry*." This judgment has since been amply confirmed. Whether the theory be true or not in substance, it has proved to be a working hypothesis of the utmost value, having provided chemists for the first time with the means of fully discussing the phenomena of chemical interchange in dilute solutions of electrolytes mathematically.

Since 1883, Arrhenius has been constantly occupied in extending the application of the views put forward in his first paper.

The conception of the almost complete dissociation into their ions of strong acids and bases and of many salts in dilute solution was fully developed by him in 1887, almost simultaneously with van 't Hoff's extension of the gaseous laws to solutions.

The work of the two philosophers was, in fact, complementary, and the extraordinary development in recent years of physical chemistry must be attributed to the cooperative influence of their concurrent views.

DARWIN MEDAL.

Mr. Francis Galton, F.R.S.

The Darwin Medal is conferred upon Mr. Francis Galton for his numerous contributions to the exact study of heredity and variation contained in "Hereditary Genius," "Natural Inheritance," and other writings.

The work of Mr. Galton has long occupied a unique position in evolutionary studies. His treatise on "Hereditary Genius" (1869) was not only what it claimed to be, the first attempt to investigate the special subject of the inheritance of human faculty in a statistical manner and to arrive at numerical results, but in it exact methods were, for the first time, applied to the general problem of heredity on a comprehensive scale.

The work thus begun was continued and extended in a long series of publications (*see* Bibliography in "Natural Inheritance," pp 219–20), conspicuously in "Natural Inheritance" (1889), a publication which marks a distinct advance in these studies, both by definition of the problems of variation and heredity and by the introduction of novel methods. Subsequently Mr. Galton, with a greater emphasis, enunciated (Roy. Soc. *Proc.*, vol. lxi., 1897, p. 401) the central conclusion to which his long investigations had led him, in the form universally familiar to biologists as "Galton's Law of Heredity," a principle now recognised as of wide application in nature.

Contributing to the total of Mr. Galton's work, numerous other subjects might be mentioned, which he has elucidated with a genius peculiarly Darwinian. In all his researches he has been a pioneer, and indeed, with the single exception of Quetelet, we may almost say that no one preceded him. His work is generally acknowledged to constitute a new departure in biology, and to form a natural continuation of Darwin's labours. Besides their intrinsic value, the special charm of his writings has exercised a notable influence on the minds of others, stimulating them to work in the same fields. It may safely be declared that no one living has contributed more definitely to the progress of evolutionary study, whether by actual discovery or by the fruitful direction of thought, than Mr. Galton.

BUCHANAN MEDAL.

Dr. Sydney A. Monckton Copeman.

The Buchanan Medal, awarded every five years for distinguished services to hygienic science or practice, is given to Dr. Sydney A. Monckton Copeman for his experimental investigations into the bacteriology and comparative pathology of vaccination.

Dr. Copeman is well known, both in this country and abroad, for his contributions to the scientific basis and practice of preventive medicine. His earliest work in this field was an investigation into lead poisoning from drinking water in Yorkshire. The importance and value of his "Report to the British Medical Association" was such as to at once attract the notice of the late Sir George Buchanan, and he was shortly after appointed one of Her Majesty's Inspectors on the Local Government Board. Then he commenced, and in such leisure time as official duties have left him has continuously prosecuted with remarkable success, important researches into the nature of the vaccine *virus*, and on the contaminations, bacterial and other, of vaccine lymph. His work has, besides results of theoretic importance, brought practical results in the form of great improvements in the storage and preservation of lymph used in this country. He has also shown the possibility of obtaining useful vaccine lymph by passage through animals other than the calf. It may also be added that he has contributed a considerable amount of knowledge to the physiological chemistry of animal pigments, and has elaborated a test for distinguishing between the blood pigment of man and that of other mammals, a test which is practicable for medico-legal inquiries.

HUGHES MEDAL.

Prof. Joseph John Thomson, F.R.S.

The Hughes Medal is awarded to Prof. Joseph John Thomson in recognition of his contributions to the advancement of electrical science, especially in connection with the phenomena of electric discharge through rarefied gases.

The explanation of the brilliant and remarkable phenomena attending electric discharge through highly rarefied gas has long remained an enigma, though it was early recognised by Maxwell and other philosophers that the simplicity of the conditions that must prevail in rarefied matter would probably some day furnish the key to much that is fundamental in electrical action. Following at a considerable interval the earlier work of Plücker and Hittorf, the improvement in the production and regulation of high vacua led Crookes into the exploration of a new and very striking class of phenomena, those grouped around the kathode rays, and he adduced much evidence, backed by the authority of Sir George Stokes, to show that these rays consist of streams of electrified particles projected from the kathode to the electric current. The nature and origin of these torrents of particles remained an unsolved question. Though Schuster showed that some kind of subpermanent dissociation of electrolytic character accompanied the electric discharge, his admirably planned attempt to determine the relation between the charges and masses of the kathode particles did not lead to decisive results; while the advances made by Goldstein, Hertz and others in Germany were dominated by the view that the phenomena were due to disturbances propagated in the ether rather than to projected particles. When, in 1889, Prof. J. J. Thomson announced, as the result of his measurements of the magnetic deflection of the kathode rays, their relation to the rays of Lenard, and other properties, that each kathode particle carried the normal electrolytic molecular charge and moved with a velocity which was a considerable fraction of that of radiation, and more especially that the mass of the particles was only about the thousandth part of the mass of the chemical atom, it was felt that, if these conclusions were confirmed, experiment had forced a way into the very ultimate foundations of physical phenomena, into regions which might fairly have been thought to be beyond human scrutiny. Weighty evidence had indeed already been adduced on theoretical grounds that any complete and consistent rationale of the known electrical laws almost demanded that electricity should be of an atomic character, like matter itself; and the magnetic action in spectra, discovered by Zeeman, illustrated and directed attention to this result; but no presumption was anywhere entertained that the electrical atom could so soon become the subject of direct experiment. By virtue of Prof. Thomson's own investigations, and of many others inspired and stimulated by him, this new field of knowledge has been widely extended. It is now known that the conductivities induced in gases by the Röntgen radiation, by chemical action, by radio-active substances, even by a hot wire, are closely connected in character and all take place by electric convection of such ultimate atomic charges.

It can hardly be doubted that the progress of this new department of knowledge will gradually enable us to see one whole stage deeper into the sources of physical phenomena.

NOTES.

AT the meeting of the Royal Society on November 27, the following were elected by ballot foreign members of the Society:—Prof. Waldemar Christofer Brögger, Prof. Gaston Darboux, Prof. Ewald Hering, Mr. George William Hill, Prof. Albert Abraham Michelson, Baron Ferdinand von Richthofen, Graf H. zu Solms-Laubach, and Prof. Julius Thomsen.

THE Emperor of Germany never neglects an opportunity of expressing his appreciation of the important part which science plays in national progress, and his remarks are not only encouraging to workers in all departments of natural knowledge, but also of value in determining the attitude of the public towards scientific work. In a speech at Aix-la-Chapelle in June last, he described the German Empire as mainly intellectual and scientific, and on November 28 he alluded to the same point in the course of a speech delivered at Görlitz, where a "hall of fame" has been erected. From a translation of the text of his

speech given by the Berlin correspondent of the *Times*, we take the following extract :—"We stand on the threshold of the development of new forces; our age demands a race which understands it. The new century is dominated by science—which includes technical skill—and not, like the last century, by philosophy. We must be men of the age. Great is the German in scientific investigation, great in his capacity for organisation and discipline. The freedom of the individual, the strong tendency towards development of individuality which is inherent in our race, is conditioned by subordination to the whole for the good of the whole. May the future, therefore, see the growth of a generation which, in the full recognition of these facts, develops in the course of joyous labour individuals who subordinate themselves to the good of the whole, to the good of the people and of the fatherland. Freedom for thought, freedom in the further development of religion and freedom for our scientific investigation—that is the freedom which I desire for the German people and would win for them."

Dr. Deslandres, astronomer at the Meudon Astro-physical Observatory, has been elected a member of the Paris Academy of Sciences in succession to the late M. Faye.

Prof. E. B. Poulton, F.R.S., will deliver the juvenile lectures at the Society of Arts this year, and has selected as his subject "Means of Defence in the Struggle for Life among Animals." The dates of the lectures will be December 31 and January 7.

We regret to announce that Prof. Ladislava Celakovského, professor of botany in the Bohemian University at Prague, died on November 24, at sixty-nine years of age.

The *Times* reports that the Swedish Academy of Sciences has conferred the Nobel prize of the year 1902 for chemistry on Prof. Emil Fischer, professor of chemistry at the University of Berlin, where he succeeded Prof. von Hofmann in 1892.

The Cape *Agricultural Journal* announces that Dr. A. Loir, of the Pasteur Institute, Paris, has proceeded to Bulawayo to establish a branch of the Institute there for the treatment of rabies by the anti-rabic inoculation method. Dr. Loir is a nephew of the late M. Pasteur, and has been engaged in the establishment of branches of the parent Institute at Sydney, N.S.W., and Tunis.

The death is announced of Prof. O. N. Rood, known by his work in experimental physics. We learn from *Science* that Prof. Rood was born in 1831, and was professor of chemistry and physics at Troy University from 1858 to 1863. For the past thirty-nine years he had been professor of physics in Columbia University. He had been vice-president of the American Association for the Advancement of Science and was a member of the National Academy of Sciences.

The committee of the class including agricultural practice and agricultural statistics at the Paris Exhibition of 1900 has decided to make a grant of 2400 francs to the agricultural section of the Paris Society for the Encouragement of National Industries, to be employed in agricultural research in such a manner as the committee of the Society determines. In his letter to the president of the Society, M. Tisserand, on behalf of the exhibition committee, expresses satisfaction that such a grant is possible as the outcome of the work of the section of the exhibition represented by him.

The Hon. F. M. Alleyne, member of the Legislative Council of Barbadoes, writes to say that in Barbadoes great success has been achieved in the cultivation of sweet potatoes and yams of the very best quality, and an endeavour is now being made to introduce these into this country as vegetable foods. Messrs. W. Pink and Sons, of Portsmouth, are importing regular supplies, and with every parcel receipts are sent for various ways of cooking both sweet potatoes and yams.

A Reuter telegram from Kingstown, St. Vincent, announces that the Soufrière was in violent eruption on November 26. Georgetown and Château Belair have again been deserted. Telephonic communication was interrupted early in the day owing to the fierce lightning. Rumblings could be heard and volcanic clouds seen from Kingstown. According to a telegram from St. Thomas, the steamer *Jare*, which has arrived there, reports that when she passed Mont Pelée on the morning of November 26, the volcano was in violent eruption.

Science states that Prof. J. J. Thomson has been invited to be the first lecturer at Yale University on the Silliman foundation. This lectureship, endowed by the late Benjamin Silliman with 85,000 dollars, is somewhat similar to the Gifford lectures of the Scottish universities, providing for a course of lectures "the general tendency of which may be such as will illustrate the presence and wisdom of God as manifested in the natural and moral world." The lectures, however, must not be "on topics appropriate to polemical or dogmatic theology."

The lecture which Sir Oliver Lodge delivered to the Institution of Electrical Engineers on November 27 was followed with much interest by a large and appreciative audience. The subject was "Electrons," and the lecturer made it his aim to expound the work which had been done in recent years, work in which the names of Crookes, J. J. Thomson, Stoney and Larmor stand out preeminent, rather than to attempt any new contribution to the theory. This was no easy matter before an audience composed chiefly of engineers, but Sir Oliver Lodge's powers were fully equal to giving a simple exposition of a difficult subject and making clear to his listeners the lines of reasoning involved and the legitimate inferences to be drawn from the experimental work.

Reuter's Agency understands that the work of the Commission dispatched to Uganda some months ago by the Royal Society and the Foreign Office to inquire into the cause of the mysterious malady known as "sleeping sickness," which has made such ravages in Central Africa, has not yet been completed. Dr. Low, the pathologist of the Commission, having finished his portion of the work, is returning home, but Dr. Castellan is continuing his bacteriological investigations in the country, and Dr. Christy, the third member of the Commission, as at present arranged, will pursue his studies along the Upper Nile, by which route he will return to England.

M. Calmette has claimed that antivenin, the anti-serum for snake-poison, is to a large extent non-specific, that is to say, cobra anti-serum, for example, would neutralise the venoms of other snakes, though perhaps not so actively as it would cobra venom. This view has been called in question by Prof. Martin and by Captain Lamb, and more recently Dr. Tidswell has found (*Australasian Med. Gaz.*, April 21) that Calmette's antivenin has little or no neutralising power when tested against the venom of the Australian tiger snake.

At a meeting held last week at the Polyclinic in connection with the Prince of Wales's Leprosy Fund, Mr. Jonathan Hutchinson, F.R.S., gave an exposition of his views upon the propagation of leprosy. He stated that he had come to the conclusion, after much study of the question, that the disease is spread only to a very small extent by anything of the nature of personal contagion, and that it is a food-disease, the living bacillus being received into the body by way of the stomach. The one article of food which was to be suspected was badly cured fish, eaten without sufficient cooking. Mr. Hutchinson,

who has only recently returned from South Africa, is shortly starting for a tour in Ceylon and India in order to investigate the ætiology of leprosy.

WE have received an advance copy of the second edition of Merck's Index. The bulk of the work is devoted to an alphabetical list of the multitude of substances which have been introduced of late years for medicinal use and the majority of which are not to be found in the pharmacopœias. Under each heading, the nature, chemical composition and physical properties, the uses and doses of the substance are indicated. Another useful list gives the composition of various test-solutions that are usually referred to under authors' names and the formulæ for which are often difficult to discover. Other tables give the nature and derivation of the organic substances of the materia medica, nature and composition of minerals, indicators, &c. Altogether, the work is a most useful one, both for the practising physician and for the chemist and physiologist, and should find a place in every laboratory.

A COPY of the catalogue of Aurora Borealis observed in Norway from the earliest times until June, 1878, has been received (xxiii + 422 large quarto pages, Christiania, 1902). This comprehensive catalogue was compiled by Prof. M. Tromholt; he died in 1896, and the laborious task of revising the manuscript and preparing the work for publication was undertaken by his friend, Prof. J. F. Schroeter, of the Christiania Observatory. The first portion of the catalogue gives, in chronological order, the year, month and day on which aurora was observed, together with the district and place, a short description of the phenomenon and the source from which the information was obtained, while a second section contains special descriptions of individual displays. The discussion of the results shows that, as regards the whole country, a maximum in the yearly period occurs about the times of the equinoxes (October and March), separated by a minimum in mid-winter. For the northern part of the country, north of 68° 30', the yearly period resembles that of the polar regions, with a maximum about the winter solstice. South of latitude 65°, the periods resemble those of middle latitudes. Prof. Schroeter has also tabulated the observations of Dr. Rubenson's catalogue of Swedish auroræ, and shows that the same results hold, for the yearly period, for the whole of Scandinavia, and for individual districts, as obtain for Norway only.

SOME tests on an interesting battery, in which the depolariser is atmospheric oxygen, are described by G. Rosset in a recent issue of the *Centralblatt für Accumulatoren-Elementen*. The cell consists of a zinc electrode dipping into a solution of salammoniac surrounding a porous jar; a semipermeable membrane of ferrocyanide of copper is formed in the interstices of the jar, which contains a carbon rod dipping into an ammoniacal solution of cupric oxide. When the cell is discharging, the cupric oxide is reduced to the cuprous state, but this diffuses to the surface and is reoxidised by the atmospheric oxygen. The tests show that the depolarising liquid serves for several discharges without renewal in any way, and the constancy of the E.M.F. during discharge is very good. The starting E.M.F. is about 1·25 volts, and this falls slowly to about 0·78 at the end of twenty or thirty days; the internal resistance is about 2·5 ohms. If the air is kept from the depolariser, the E.M.F. falls considerably, but recovers on its being readmitted.

THE Cambridge Scientific Instrument Company has sent us a pamphlet on the measurement of temperature by electrical means, which describes the different types of resistance and thermoelectric thermometers which they manufacture. These thermometers possess the advantage, not only of being suitable for measuring any temperature up to 1000° C. or 1500° C., but also of enabling the reading to be made at any distance from the place at which the high temperature exists. They thus do for thermometry what electrical instruments have done for electrical measurements; it is possible, for example, to read the temperature, say, of a hospital ward in the engine-room instead of in the ward itself, just as it is possible to read in the central station the electrical pressure at the consumers' terminals. The apparatus described in the list before us ranges from the simple thermoelectric couple or resistance wire in a suitable protecting tube to the elaborate Callendar recorders. Instruments reading direct in degrees centigrade can be supplied with the thermometers. The different purposes for which electric thermometry is the best, and often the only, means of measuring temperature are too numerous to mention; the convenience and high accuracy of the method will further recommend it to all who have under their control operations involving temperature regulation.

READERS of NATURE are familiar with the work which has been done by Prof. Kahlenberg tending to disprove the dissociation theory of electrolysis. A short paper summarising the principal arguments against the theory was read by Prof. Kahlenberg before the American Electrochemical Society last April. We commend this paper to all interested in electrochemical theory, especially to those who believe firmly in "ionisation." Briefly, the charges against the hypothesis of Arrhenius are the following. The very generalisation which gave birth to the theory, that abnormal osmotic pressure indicated an electrolyte, and the converse, has not been supported by further experiment. The theory, if it accounts for anything, only accounts for the behaviour of dilute solutions, and is consequently of very limited applicability. There is no experimental evidence, worthy the name, justifying the application of the theory to fused electrolytes. There is no question but that these charges are well supported, and that the ionic theory, if it has given rise to much useful work, has also greatly checked development in some directions, notably that of research with concentrated solutions. It is also a regrettable fact that writers on electrochemical subjects seem to take a pleasure in expressing *facts* in terms of the ionic theory when there is absolutely no necessity for so doing, which, doubtless, to the non-discerning, gives confirmation, in reality fictitious, thereto; without going so far as Prof. Kahlenberg and asserting that the doom of the dissociation hypothesis is already sealed, we believe that those who write in this way are running a great risk of rendering their contributions unintelligible to future generations of electrochemists.

STATISTICS of the mineral production in India for the years 1892 to 1901 have been issued by the Department of Revenue and Agriculture (Calcutta, 1902). The output of coal has increased from $2\frac{1}{2}$ to more than $6\frac{1}{2}$ millions of tons. In the same period, the production of gold has trebled, being 531,766 ounces in 1901, the value being about two millions sterling.

WE have received the general report by the director, Mr. C. L. Griesbach, on the work of the Geological Survey of India for the year ending March 31, 1902. There are brief reports on the field-work carried on in the Madras Presidency, in Burma, Assam, the Punjab, the Himalayan Ranges, Baluchistan and Sind. Inquiries into the occurrence of gold, copper and coal were made in certain districts, without, however, any important economic results. Some of the so-called old workings for gold which abound in Chota Nagpore are nothing more than old prospecting shafts and trenches, and were probably abandoned without the discovery of any paying reefs. One narrow reef gave encouraging results, but only a small outcrop was observed. Prof. R. Zeiller has completed a report on the flora of the Lower

Gondwana Series (permo-Triassic), and this is published with seven plates in the *Palaeontologia Indica* (new series, vol. ii., 1902).

THE annual report of the Geological Commission of the Cape of Good Hope for 1900 (dated 1902) has only just been received. The operations of the Survey were naturally hampered by the war, and the main work was in the districts on the west of the Karoo, including the Cederbergen and part of the country between these mountains and the sea. It was carried on by Messrs. A. W. Rogers and E. H. L. Schwarz, under the direction of Dr. Corstorphine, who has since resigned his position. Their labours have resulted in the discovery of a new formation, the "Ibiquas Series," comprising slates, sandstones and conglomerates, which overlie the Malmesbury beds and underlie the Table Mountain Sandstone. Evidence of local glacial action has been met with in the Table Mountain Sandstone. The Dwyka Conglomerate has been found to rest with marked unconformity on the older rocks as it is traced northwards. Basic dykes and sheets of the same type as those intrusive in the younger rocks of the central Karoo, have been found in nearly all of the older series of strata.

WE have received a report on the Terlingua quicksilver deposits of Brewster County, Texas (*Bulletin* No. 4 of the University of Texas Mineral Survey, 1902), by Mr. B. F. Hill, under the direction of Prof. W. B. Phillips. It is mentioned that at Comanche Spring, a small "seep," seven miles north of the Rio Grande, the limestone bluffs have been covered in a number of places with rude paintings of characteristic Indian design. The artists were without doubt the Comanche Indians, and the vermilion pigment was prepared from cinnabar. Of late years, researches have been made in the district which show that cinnabar and also native mercury occur in the Cretaceous limestones, clays and shales. These strata are invaded by eruptive rocks, to the presence of which the quicksilver deposits are considered to be indirectly due, the ore having been formed from hot springs. The cinnabar is found in definite crystals and in large amorphous masses; other mercury compounds likewise occur, while the native quicksilver is generally mixed with crystalline masses of calcite, and occupies the interstices between them sometimes in a quantity weighing twenty pounds.

THE second part of the *Aarbog* of the Bergen Museum for the current year contains a paper, by Mr. D. Bergendal, on Arctic nemertine worms, in the course of which several new generic and specific types are described. One of the former, Hubrechtella, is named in honour of the illustrious professor of zoology at Utrecht.

BY the discovery of those of the great black species (*Calyptorhynchus macrorhynchus*), which are laid in the hollow branches of gum-trees, Mr. D. le Souëf (*Victoria Naturalist*, vol. xix. No. 6) has succeeded in filling the one remaining gap in our knowledge of the eggs of Australian cockatoos.

ASYMMETRICAL development of the tracheal tubes in the fore-wings of a female specimen of the North American moth *Telea polyphemus* affords, according to Dr. G. Enderlein (*Zool. Jahrb.—Abtheil. für Anatomie*), important evidence as to the phylogeny of the Saturniidæ and the developmental history of the Lepidoptera in general.

MORPHOLOGISTS will be much interested in a paper, by Mr. E. Starks, on the shoulder-girdle of the hemibranchiate fishes (sticklebacks, flute-mouths, trumpet-fish, &c.), published in No. 1301 of the *Proceedings* of the U.S. Museum. Many emendations on previous determinations are made, and it is urged that the group is certainly entitled to rank as a suborder of equal value with the Percesoses.

THE phylogeny of the Proboscidea forms the subject of a paper by Dr. F. Ameghino published in vol. vii. of the *Anales* of the Buenos Aires Museum. The author attempts to show that the Patagonian genius Pyrotherium, which he regards as of Upper Cretaceous age, is the proximate ancestor of the group in question. This form, or its descendants, migrated into Africa, where it gave rise to the recently discovered Palæomastodon and Mœritherium, the former of which is admitted to be the progenitor of the mastodons; the latter spread over the world until one of them reached South America, the home of its ancestors! If, as is quite possible, Pyrotherium is really a proboscidean, it has to be proved, before the author's views can be accepted, first, that it is of Cretaceous age, and, secondly, that it is not itself an immigrant from Africa. It will be unnecessary to follow the author in his attempt to derive Pyrotherium—and so elephants—from a Jurassic (?) South American marsupial.

THE *Monthly Review* for December contains the first part of a contribution by the Rt. Hon. Sir Edward Fry, F.R.S., on the age of the inhabited world and the pace of organic change.

THE annual report of the Liverpool Astronomical Society, a copy of which has just been received, contains an interesting address by the president, Mr. W. E. Plummer, upon the various departments of astronomy in which observers, with or without telescopes, may do useful work if they are inspired by the true scientific spirit.

WE have received numbers 6-11 of vol. xi. and numbers 1-8 of vol. xii. of the *Transactions* of the Academy of Science of St. Louis. The separate parts are each devoted to a single subject, and there is no regular interval of time between the publication of consecutive issues. Many of the contributions are of direct interest only to American men of science, while others will appeal to scientific workers everywhere. Among the latter class in the numbers of this year may be mentioned Mr. A. S. Chessin's essays on the true potential of the force of gravity and on the motion of gyroscopes; and in vol. xi., the reviews of the progress in physics and botany in the nineteenth century, by Prof. F. E. Nipher and Dr. William Trelease respectively, and the paper on some interesting molluscan monstrosities, by Mr. F. C. Baker.

THE October number of the *Journal* of the Sanitary Institute (vol. xxiii. part iii.) contains the addresses to the various sections at the Manchester congress of the Institute. Sir James Crichton-Browne spoke upon the dust problem, and gave an analysis of the dust from a bedroom which contained more than 50 per cent. of organic matter, fragments of animal and vegetable fibres, epithelial scales, starch granules and pollen. Prof. Delépine discussed the epidemic of arsenical poisoning which occurred in the north in 1901, and stated that with Reinsch's test less than one part of arsenious acid in 10,000,000 parts of beer can be detected. Prof. Sherrington gave an interesting address upon school hygiene, and Dr. Shaw one upon the treatment of smoke, printed in NATURE of October 30 (vol. lxvi. p. 667). The popular lecture by Sir W. J. Collins was entitled "The Man *versus* the Microbe," in which he suggests that our views upon the specificity of disease and the immutability of bacteria should be modified in the light of the doctrine of evolution.

THE thirty-fifth volume of the "Journal and Proceedings of the Royal Society of New South Wales," covering the year 1901, provides convincing evidence of the scientific activity which exists in many of the important countries of the British Empire. From time to time, similar portly volumes are received from various colonies, all containing numerous important contributions to science, and it becomes increasingly difficult for a worker in any branch of knowledge to acquaint himself even with the new researches of British men of science. The volume before

us contains, in addition to the annual address by the retiring president, Prof. A. Liversidge, F.R.S., three contributions by the new president, Mr. H. C. Russell, F.R.S., one of which briefly discusses the relation between the moon's motion in declination and the quantity of rain in New South Wales, in which the author is convinced that "seeing the rain is shown so clearly to come in times of abundance, when the moon is in certain degrees of her motion south, and when the moon begins to go north, then droughty conditions prevail for seven or even eight years, a phenomenon repeated for three periods of nineteen years each, that it is either a marvellous coincidence, or there is a law connecting the two phenomena." Mr. R. H. Mathews contributes an important paper on "The Thurrawal Language," and shorter accounts of some aboriginal tribes of Western Australia and of rock-holes used by aborigines for warming water. Mr. J. H. Maiden, Government Botanist and Director of the Botanic Gardens, Sydney, gives an exhaustive summary of the gums, resins and other vegetable exudations of Australia, as well as interesting historical notes relating to the death of Captain Cook. Mr. G. H. Knibbs also writes two important papers, that on a theory of city design being of wide interest. These papers by no means exhaust the important contributions to science contained in the volume, but since reports of the proceedings of the Society regularly appear in our columns under "Societies and Academies," it is unnecessary to refer at any greater length to the scientific work being done in New South Wales.

THE additions to the Zoological Society's Gardens during the past week include two Vervet Monkeys (*Cercopithecus lalandii*) from South Africa, presented by Miss Barlow; an Equine Antelope (*Hippotragus equinus*) from Bechuanaland, presented by Major Chas. Fredk. Minchin, D.S.O.; three Fat Dormice (*Myoxus glis*) European, presented by Dr. L. H. Gough; a Mongoose Lemur (*Lemur mongoz*) from Madagascar, two Mexican Snakes (*Coluber melanoleucus*) from Mexico, deposited; two Snake Fishes (*Polypterus senegalus*) from Fashoda, received in exchange.

ERRATUM—In parenthesis near the end of letter on "Summer and Winter" (p. 81), "The average mean temperature of summer below 61°·2," for *below* read *being*.

OUR ASTRONOMICAL COLUMN.

OBSERVATIONS OF THE PERSEID SHOWER.—Herr Koss, director of the Pola Observatory, communicates to No. 3830 of the *Astronomische Nachrichten* the results of the observations of Perseids made at that observatory on August 8, 9 and 10.

The times of appearance, the exact path, the magnitude and the time of duration of each meteor are recorded for ten Perseids seen on August 8, sixteen seen on August 9, and thirty-three seen on August 10. In addition to these, thirteen Perseids and sixteen sporadic meteors were seen, but not mapped.

The position of the radiant point for August 9 and for August 10 was estimated to be $\alpha = 2h.\ 32m.$, $\delta = +56°\cdot5$ and $\alpha = 3h.\ 2m.$, $\delta = +54°\cdot5$, respectively.

NEW VARIABLE STAR, 16, 1902, DELPHINI.—From photographs taken at Moscow by M. S. Blakjo, Madame Ceraski has found that the star B.D. $+16°\cdot4290$, having the position $\alpha = 20h.\ 25m.\ 59s.\cdot5$, $\delta = +16°\ 57'\cdot2$ (1855), is a variable.

In the catalogue, the magnitude of this object is given as 9·3, and this was confirmed on a negative taken on August 18, 1900. On a plate obtained on August 17, 1901, however, the star does not appear, and, according to the magnitudes of the neighbouring stars which do appear, it must therefore have been fainter than the eleventh magnitude. Visual observations confirmed this latter value (*Astronomische Nachrichten*, No. 3830).

EVOLUTION OF AËROGRAPHY.—In No. 170 of the *Proceedings* of the American Philosophical Society, Mr. Percival Lowell reviews the various steps which have taken place in our knowledge and mapping of the surface of Mars.

By a series of twelve maps, arranged in chronological order, he shows the gradual development in the amount of detail seen and recorded, from the map of Beer and Madler, published in 1840, to that published by himself in 1901. From comparisons of these maps, he divides the history of aërography into three periods, viz., 1840–1876, large dark and light markings shown; 1877–1892, "canals" in bright regions detected; 1893–1902, "canals" in the dark regions detected; and also draws the following three deductions therefrom:—(1) The series agree fundamentally. (2) The regularity of the "canals," as recorded by Schiaparelli, was not due to any predisposition on the part of that observer, but was gradually forced upon him as he became more familiar with the surface of the planet. (3) All the maps show a general evolution, from simple to complex, in the detection of the surface markings of the planet.

A SIMPLIFIED FORM OF FOUCAULT'S PENDULUM.—The reinstallation of Foucault's famous experiment at the Pantheon by MM. Berget and Flammarion has, according to M. D'Arsonval, called forth many ingenious devices for proving the same result by means of a simpler apparatus.

Of these devices, M. D'Arsonval describes, in the *Comptes rendus* for November 17, the one which, in his opinion, is the simplest and best.

The main point of this device is the simplicity of the method of suspension. A steel wire, 0·035mm. in diameter, carries a leaden ball, which is covered with copper and weighs about $2\frac{3}{4}$ lbs., and is fixed to the ceiling by an ordinary nail. Its upper end is then clamped in a metal block, so that it is immovable above the lower face of the block, but free to swing about the point where it enters this face from below, and the block is then screwed to the ceiling or other suitable support. A pendulum suspended in this manner is capable of swinging for about three hours.

The whole apparatus is contained in a small wooden box, which also carries the sand in which the pendulum pointer marks the trace of its plane of swing, and is accompanied by a small model pendulum, which may be used to illustrate the principle of the invariability of the plane of oscillation.

The simplicity, the compact form and the low price (20 francs) of this device should render possible its use in schools and colleges, where hitherto the students have had to depend upon descriptions and illustrations for their knowledge of this important experiment, or else pay a visit to the western galleries of the Victoria and Albert Museum, where a large model may always be seen and, if formal representations be made to the authorities, demonstrations may be given.

PHYSICAL CHEMISTRY APPLIED TO TOXINS AND ANTITOXINS.

A VERY important contribution to our knowledge of the toxins and antitoxins is contained in the "Festskrift" recently published to celebrate the inauguration of the State Serum Institute at Copenhagen, in the form of a paper with the above title by Arrhenius and Madsen. In passing, we note with pleasure that English has been chosen as the international linguistic medium for the entire contents of the volume. The necessity for collaboration between the representatives of different branches of science for the satisfactory study of many of the complex problems of physiology, bacteriology and pathology is gradually becoming generally recognised, and in the present instance we have a striking example of the joint work of two celebrated investigators on a subject lying on the common boundary of their special provinces of knowledge and experience.

It is well known that tetanus toxin, prepared by filtering off the bacteria from a broth culture and saturating with ammonium sulphate, contains two distinct toxic substances, a *spasmin*, which produces the characteristic convulsions, and a *lysin*, which hæmolyses the red blood corpuscles of many animals. In the same way, the antitoxin produced in the serum of animals immunised against tetanus contains two distinct antitoxic substances, an *antispasmin* and an *antilysin*.

It has, moreover, been shown by Madsen that experiments on the properties and mutual relationships of the tetanus lysin and antilysin can be performed with great facility and comparatively great accuracy on blood *in vitro*, the uncertainty attendant upon animal experiments and the great expenditure of time required by them being thus avoided.

The aim of the present investigation was to study the hæmolytic action of tetanus lysin and its reaction with antilysin in the light of ordinary chemical reactions, and to compare both these phenomena with similar actions brought about by substances of known molecular weight, constitution and purity.

The method of estimating the hæmolytic power, which was employed in all the experiments, consisted in allowing the substance under examination to act for a given time upon an emulsion in normal saline, or other liquid, of a known quantity of well-washed blood corpuscles, and then estimating the amount of hæmolysis produced colorimetrically by comparison with standard tubes prepared from varying quantities of the same blood by complete hæmolysis with distilled water.

The investigation falls naturally into two parts, the first of which deals with the hæmolytic action of tetanus lysin compared with that of caustic soda and ammonia.

The hæmolysis of a blood corpuscle by a base such as caustic soda or by tetanus lysin is a phenomenon of considerable complexity and appears to take place in two stages—the combination of the hæmolytic agent with the material of the corpuscle, and the hæmolysis of this compound by the "lysin" which remains free. The three substances under investigation differ from each other in the rate at which they unite with the corpuscles and also in the stability of the compounds which are produced.

Caustic soda combines very rapidly and forms a very stable compound; the consequence of this is that when a certain definite number of blood corpuscles are present, practically the whole of the alkali is taken up and very little hæmolysis occurs. With small amounts of blood, hæmolysis is complete, but as the amount of blood is increased beyond the amount which can be completely hæmolysed, the alkali is thereby withdrawn in increasing amounts from the solution, so that the extent of hæmolysis rapidly diminishes. Tetanolysin, on the other hand, combines much more slowly with the corpuscles and forms a much less stable compound, which is partially decomposed into its constituents, or hydrolysed, by the water of the solution. Hence, in the case of the lysin solutions, there is always some free lysin to effect the hæmolysis of the lysin-corpuscle combination, and, as a consequence, the falling off after the maximum is not nearly so marked. Ammonia takes up a position intermediate between caustic soda and lysin.

All these hæmolytic actions are affected by the presence of certain foreign bodies, among which salts, albumin and serum have hitherto been examined. It seems probable that salts have two distinct effects. In the first place, they probably render the corpuscles more susceptible to the attack of the hæmolytic agent, and hence tend to increase hæmolysis. This tendency is not counteracted in any way in the case of the tetanus lysin, and hence an increase in the action is in this case observed. The compounds of the alkalis with the corpuscles, on the other hand, are affected by salts containing the same ion, much in the same way as a weakly dissociated salt, in which case the dissociation is decreased and the salt then enters less readily into reaction. Hence the caustic-soda combination is affected in this way by sodium salts and, since the diminution of hæmolysis thus produced outweighs the increase due to the effect of the salt on the corpuscles, a nett decrease of action is observed. The ammonia combination is less strongly dissociated than the soda combination, and is therefore still more strongly affected by the presence of ammonium salts.

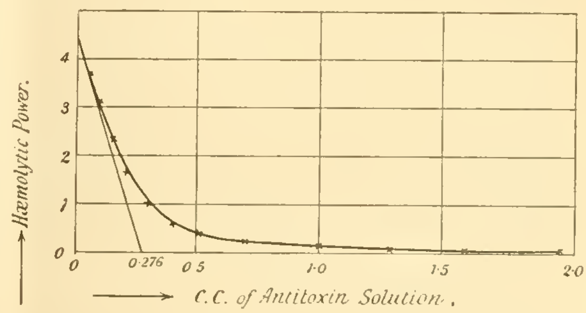
The dissociation spoken of in this case is the electrolytic dissociation of a salt or salt-like compound into its ions, and must not be confused with the hydrolysis mentioned above. Thus a salt-like sodium carbonate is at the same time partly dissociated into its ions, and partly hydrolysed by the water of the solution into caustic soda and carbonic acid; sodium chloride, on the other hand, is much more completely dissociated into its ions, but is practically not hydrolysed at all.

The effect of egg albumin and normal serum is also to diminish the hæmolytic power, both of the bases and of tetanus lysin, but whilst the effect on the bases is very slight, that on the lysin is considerable. It would seem that in each case the albumin combines with the hæmolytic agent, forming a compound in which the hæmolytic power is modified to a certain extent. The properties of caustic soda and ammonia are only slightly affected; those of the tetanus lysin, on the other hand, are more profoundly modified. This explanation is confirmed by the fact that the further addition of albumin exerts no appreciable effect after a certain limit has been reached. Normal serum, on the other hand, has a progressively increasing effect on the lysin, and in fact behaves like a mixture of a large amount of albumin with a small amount of an antitoxin.

Further information is gained as to the nature of the hæmolytic action by the determination of the velocity of the change, and this reveals a still greater complexity. The reaction exhibits a very decided *period of induction*; when the substances are first mixed, the change begins to take place at a very low rate, which gradually increases as the change proceeds. Such a period of induction occurs in certain well-known chemical reactions, although its exact significance is not perfectly understood. In the case under consideration, the authors suggest that it "depends on the circumstance that the red blood corpuscles' cellular membrane must be destroyed before hæmolysis can occur." The actual velocity is found to be proportional to the concentration of the hæmolytic agent, so that if the dose be doubled, the time required to produce a given amount of hæmolysis is halved. This result is of great importance because it shows that the hæmolytic action of bases is not due to the hydroxyl ions, in which case the velocity would be proportional to the square root of the concentration. The same thing is shown by the fact that ammonia acts more rapidly than caustic soda, although it is much less strongly dissociated.

The second part of the investigation deals with the important subject of the action of the antilysin on tetanus lysin.

When increasing quantities of antilysin are added to a fixed amount of lysin, the hæmolytic power of the mixture is not diminished in direct proportion to the amount of antilysin added, but the effect of each successive portion of antilysin is less than that of the preceding one, the diminution of hæmolytic power being rapid at first and then becoming more and more gradual. If the results be plotted with the amounts of



antilysin added as abscissæ and the hæmolytic powers of the resulting mixtures as ordinates (the amount of lysin being constant throughout), a curve of the form shown above results. This curve represents what is usually know as the *toxin spectrum* of Ehrlich.

When we compare this phenomenon with the action of an acid on an alkali, we find that it does not resemble what occurs when an equivalent of hydrochloric acid is added to caustic soda, for in this case the alkalinity diminishes in direct proportion to the acid added, the last portion of acid having exactly the same neutralising effect as the first.

On the other hand, it corresponds precisely with the phenomena observed when a base such as ammonia is treated with a weak acid, like boric acid. In fact, if ammonia be treated as a lysin and boric acid as an antilysin, and hæmolytic experiments be made in precisely the same way as with tetanus lysin and antilysin, the curves of hæmolytic power produced in the two cases are of precisely the same kind. Now the phenomena which occur when boric acid is added to ammonia and in similar cases have been carefully examined by physical chemists, and they are known to be due to the fact that, in a solution of this kind, the ammonium borate which we should expect to be formed is partially hydrolysed by the water into its components, so that the liquid contains ammonium borate, water, free ammonia (ammonium hydrate) and free boric acid. The case is susceptible of mathematical treatment according to Guldberg and Waage's law, and the equivalents of the substances and the coefficient of dissociation can be calculated from the observations.

Precisely the same can be done for the tetanus lysin and antilysin, and the natural conclusion is that these two changes are of the same kind, a reaction taking place in each case between two molecules and resulting in the formation of two molecules of the products. It does not in any way follow that the *substances* concerned are of the same chemical type, and in fact other considerations render this very improbable.

In the particular experiment quoted, the amount of antilysin solution which was chemically equivalent to the lysin employed was 0·276 c.c. When this quantity of antilysin was added, however, the hæmolytic power remained equal to 36 per cent. of the original, whilst even after the addition of seven times the equivalent, the power was still 1·8 per cent. of the original. These facts, nevertheless, do not indicate the presence of a series of lysins of different hæmolytic powers and affinities for antilysin, any more than the precisely similar phenomena observed with ammonia and boric acid indicate the presence of a series of bases possessed of different hæmolytic powers and affinities for boric acid. It is therefore unnecessary to suppose, as Ehrlich has done for diphtheria toxin, that proto-, deutero- and trito-toxins as well as toxones are present.

All the phenomena are explained by the presence of a single lysin, the compound of which with its antilysin is partially decomposed into its constituents by water. Recent experiments of Dreyer and Madsen show that these conclusions may fairly be extended to the constitution of diphtheria toxin.

The deterioration of tetanus lysin is a subject of great interest in connection with the theory of toxins, and its study has also yielded interesting results, although it has not yet been pushed very far. The examination of an altered lysin by the method described above serves to indicate which of its constants—the equivalent or the coefficient of dissociation—has been altered. To take a single example, the hæmolytic power of a solution of lysin was found to have diminished to one-sixth in about five days. Examination showed that its equivalent had not altered, but that its coefficient of dissociation had increased by 50 per cent. As a result of this increase, the hæmolytic power of this lysin would be diminished to a less extent than that of the original lysin by a given dose of antilysin. The effect of deterioration in this case can therefore be explained by supposing a slight change to have occurred in all the molecules of the lysin, "perhaps a transformation into a metameric compound, less toxic," possessing an increased coefficient of dissociation and an undiminished combining power for antilysin. Ehrlich's explanation, on the other hand, would be that five-sixths of the lysin had been converted into a non-hæmolytic substance (toxoid) which had a greater affinity for the antilysin than lysin itself and was therefore "neutralised" first.

This explanation may be applicable in some cases, but, as will be seen, it is not necessarily required by the facts.

A further point of interest is that lysin and antilysin unite slowly and at a rate which can be measured. The investigation of this reaction has been carried out to a certain degree, and its further examination will probably throw more light on the nature of the change which occurs.

If the results of the authors are accepted, a great simplification of the present ideas as to the constitution of toxins will be necessary. A point which is of fundamental importance and appears to call for further examination is the mode of action of the lysin molecule in hæmolysis. In other words, does hæmolysis take place between the lysin-corpuscle and free lysin, as is the case with caustic soda, or does the lysin molecule which forms the combination bring about the hæmolysis by means of another group contained in its molecule?

A. HARDEN.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—An important change has recently been made in the regulations for Responsions. The change affects the examination in the Elements of Geometry. Instead of Euclid's Elements Books i. and ii., with Euclid's axioms and Euclid's sequence of propositions, the subject will in future be defined as the subject-matter of certain specified portions of Euclid's Elements Books i., ii., iii., and the papers will contain elementary questions on this subject-matter and easy deductions from the specified propositions. The regulations state that any method of proof will be accepted which shows clearness and accuracy in geometrical reasoning, and that algebraical proofs of certain propositions in Book ii. will be allowed. The change is to come into force in the Michaelmas term of 1904. The announcement made by the Board of Studies for Responsions, in the *University Gazette* for November 25, reads as follows:—"In the regulations as to the Elements of Geometry (*Examination Statutes*, 1902, p. 18), the words 'Euclid's Elements, Books i., ii. Euclid's axioms will be required, and no proof of any proposition will be admitted which assumes the proof of anything not proved in preceding propositions of Euclid,' have been struck out, and the following words substituted:—'Elementary questions, including propositions enunciated by Euclid and easy deductions therefrom, will be set on the subject-matter contained in the following portions of Euclid's Elements, viz., Book i., the whole, excluding propositions 7, 16, 17, 21; Book ii., the whole, excluding proposition 8; Book iii., the whole, excluding propositions 2, 4–10, 13, 23, 24, 26–29. Any method of proof will be accepted which shows clearness and accuracy in geometrical reasoning. So far as possible, candidates should aim at making the proof of any proposition complete in itself. In the case of propositions 1–7, 9, 10, of Book ii., algebraical proofs will be allowed.' This change will come into force at the examination of Michaelmas term, 1904."

Sir Oliver Lodge has been appointed the Romanes lecturer for next year.

ON Wednesday evening, December 10, a paper on "French Rural Education, and its Lessons for England," will be read by Mr. Cloudesley Brereton at the Society of Arts.

THE clerk of the Privy Council has sent an official notice to the authorities at University College, Liverpool, fixing the hearing of the petition in regard to the proposed Liverpool University for Wednesday, December 17.

THE annual meeting of the Association of Technical Institutions will be held at the Goldsmiths' Hall, London, on Tuesday, January 6, 1903. The president, Lord Avebury, will occupy the chair, and an address will be given by the president-elect, Sir John Wolfe Barry, K.C.B., F.R.S.

MR. J. S. MACDONALD has been appointed to succeed Prof. Myers-Ward in the chair of physiology at Sheffield University College. Mr. Macdonald, who is at present assistant lecturer in physiology at Liverpool University College, takes up his new appointment in January next. Prof. Myers-Ward goes to Charing Cross Hospital as lecturer in physiology.

THE *British Medical Journal* announces that the Board of Trustees of Cornell University, New York, has arranged to purchase sixteen additional acres of land, and to erect new buildings, including the Hall of Physics, for which Mr. John D. Rockefeller gave a quarter of a million dollars, and a Hall of Arts and Humanities, upon which a like amount is to be expended. In connection with this University, it is of interest to notice that professors of the University who reach the age of seventy years will hereafter be retired with a pension. Their salary will be continued for one year, and they will thereafter receive 1500 dollars a year for four years, which time will doubtless be extended. They will act as special lecturers with such duties as may be assigned to them.

WE regret to see that Sir Michael Foster has written to the chairman of his Parliamentary Committee to say he feels compelled to resign his seat as member of Parliament for the University of London. He hoped to be relieved of his duties in the House of Commons at the beginning of the present term, but now, at the request of his committee, has deferred his actual resignation until the close of the present session. Among the names mentioned in connection with the vacancy thus caused are those of Sir Henry Roscoe, for some time vice-chancellor of the University, and Sir John Williams.

WRITING to the *Times*, Mr. A. C. Holzapfel points to the striking difference between English and German fees for scientific instruction. One of his sons studied chemistry at Aachen, and the fees for lectures, laboratory work, breakages, &c., were between 6*l.* and 7*l.* yearly. Another son attended King's College, London, for a course of work similar to that

his brother had had in Germany, and the fee was 47*l.* 13*s.* 9*d.* for a year. The explanation is given by the secretary of the London college, who pointed out in a letter to Mr. Holzapfel that "the continental colleges are endowed by the State, but in England they have to live on the fees of students for the most part, with a very small grant from the State in some cases and what they can raise voluntarily from the public." But it is evident that while the highest form of instruction in science can be obtained at so small a cost, there will never be a lack of properly trained men to look after the manufactures of Germany.

FULL particulars have now been published of the first annual conference of persons in the north of England concerned in primary, secondary, technical and other forms of higher education, which was announced in our issue for July 17. The conference will be divided into four sessions—two meetings on each of the days January 2 and 3, 1903—presided over respectively by Mr. M. E. Sadler, director of special inquiries to the Board of Education; Prof. H. E. Armstrong, F.R.S., Prof. Smithells, F.R.S., and Prof. L. C. Miall, F.R.S. There will be a reception by the Lord Mayor of Manchester of members of the conference on January 2, in the Municipal School of Technology, Manchester, where the meetings will be held, after which various papers will be read. Miss S. A. Burstall, head mistress of the Manchester High School for Girls, will take up the subject of the curriculum in different types of schools. Dr. Kimmins, at the afternoon meeting of the first day, deals with the coordination and delimitation of science teaching in various grades of schools. The methods of teaching experimental science in its early stages will be discussed on the morning of January 3, Mr. W. French, principal of the Storey Institute, Lancaster, taking up physics, and Mr. R. L. Taylor, of the Central School, Manchester, considering chemistry. At the last meeting, Mr. H. W. T. Wager will introduce the subject of methods of nature-study. Great care has been taken to encourage discussion at each meeting; the names of well-known teachers are included in the programme as having promised to contribute to the debates. In connection with the conference, there will be an exhibition of apparatus, preparations and diagrams, such as teachers themselves have prepared or which pupils have made, to illustrate methods of nature-study and the teaching of experimental science. A class-room, fitted up as a model of what it is desired should be provided for the teaching of physics and chemistry in their early stages, will form part of the exhibition. The admission to the conference will be free, by ticket, to be obtained from the honorary secretaries, Dr. H. Lloyd Snape, Director of Education to the Lancashire County Council, and Mr. J. H. Reynolds, Director of Technical Instruction for the city of Manchester and principal of the Manchester Municipal Technical School, which is the office of the conference.

SCIENTIFIC SERIALS.

Transactions of the American Mathematical Society, vol. iii. No. 4 (October).—G. A. Miller, on the groups of order p^m which contain operators of order p^{m-2}. It appears that if $p>2$ and $m>5$, there are two and only two such groups not containing either an invariant cyclic subgroup of order p^{m-2} or else an abelian subgroup of type $(m-2, 1)$. These two groups are conformal respectively with the abelian groups of type $(m-2, 2)$ and of type $(m-2, 1, 1)$.—C. A. Scott, (1) on the circuits of plane curves; (2) on the real inflexions of plane curves.—J. Hadamard, on the theory of plane elastic plates.—E. J. Wilczynski, covariants of systems of differential equations, and applications to the theory of ruled surfaces. The system considered is $y''+p_{11}y'+p_{12}z'+q_{11}y+q_{12}z=0$ and another similar equation with z'' for y''. All covariants can be expressed in terms of three, together with invariants.—A. S. Gale, on the rank, order and class of algebraic minimum curves.—H. F. Blichfeldt, on the determination of the distance between two points in space of m dimensions. Without assuming the continuity and independence of the coordinates, but assuming that distance-relations exist, a series of axioms is laid down and possible forms deduced for the analytical expression for the distance between two points.—H. Maschke, on superosculating quadric surfaces.—E. H. Moore, a definition of abstract groups.—A. Emch, algebraic transformations of a complex variable realised by linkages.

American Journal of Mathematics, vol. xxiv. No. 4 (October).—M. Bôcher, on systems of linear differential equations of the first order. This contains proofs of some existence-theorems by a method of successive approximation.—T. M. Putnam, on the quaternary linear homogeneous group and the ternary linear fractional group. The determinant being unity, and the group being symbolised by substitutions, the canonical forms of the generators fall into eleven principal types, with various subdivisions. The periods of the substitutions are considered, and different commutative subgroups investigated.—A. N. Whitehead, on cardinal numbers. The results of this paper are all expressed in Peano's symbolism, on which there is an introductory section.—G. A. Miller, on a method of constructing all the groups of order p^m (p being any prime).—H. F. Stecker, non-Euclidean properties of plane cubics and of their first and second polars. This is a continuation of a former paper in vol. xxii. of the same journal.

Annals of Mathematics (2) vol. iv. No. 1. (October).—G. A. Bliss, on the geodesic lines on the anchor-ring. The author obtains explicit formulæ, involving elliptic functions, which define a doubly infinite family of geodesics. He also shows that, according to Mangoldt's classification, the points on the inner equator are of the first kind and all others of the second kind. Good illustrative diagrams are given.—H. F. Blickfeldt, proof of a theorem concerning isosceles triangles.—L. E. Dickson, an elementary exposition of Frobenius's theory of group-characters and group-determinants.—E. V. Huntington, on Mr. Ransom's mechanical construction of conics.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, November 19.—Dr. J. Emerson Reynolds, V.P.R.S., president, in the chair.—The "dynamic isomerism" of thiourea and ammonium thiocyanate. When the ammonium salt is heated, there is formed a definite compound of this with 25 per cent. of thiourea formed from it; further, melting-point curves of mixtures of these two substances show that other molecular combinations occur.—Isomeric partially racemic salts containing quinquevalent nitrogen; part 8, resolution of the hydrindamine camphor sulphonates, by Dr. F. S. Kipping. The author has confirmed the theory proposed by him in 1899 to account for the existence of these salts by the resolution of the partially racemic salt into four isomerides.—The oxime of mesoxamide and some allied compounds, by M. A. Whiteley. A description of the disubstituted derivatives of mesoxamide, all of which possess the characteristic properties of furnishing yellow alkali salts and purple ferrous compounds.—Interaction of ketones and aldehydes with acid chlorides, by F. H. Lees. When methyl n-nonylketone is acted upon by benzoyl chloride, there is formed β-benzoxyundecylene; this reaction has been extended to other ketones, and a series of benzoxyolefines so produced.—The synthesis of $\alpha\alpha$-dimethylglutaric acid, hydroxy-$\alpha\alpha$-dimethylglutaric acid, and of the *cis*- and *trans*-modifications of $\alpha\alpha$-dimethylglutaconic acid, by Dr. W. H. Perkin and A. E. Smith.—A reaction of some phenolic colouring matters, by A. G. Perkin and C. R. Wilson. Potassium derivatives of a number of naturally occurring colouring matters have been prepared by interaction with potassium acetate.—Note on mixtures of constant boiling point, by Dr. S. Young. The composition of the mixture of carbon tetrachloride and methyl alcohol having the minimum boiling point is shown to contain 80 per cent. of the former.—The vapour pressures and boiling points of mixed liquids, part 2, by Dr. S. Young and E. C. Fortey. Part 3, by Dr. S. Young. An investigation of the formula proposed by the authors expressing the relation between the vapour pressure of the mixture and those of its constituents. Note on the condensation points of the thorium and radium emanations, by E. Rutherford and F. Soddy. When the emanations from thorium and radium compounds are passed through a copper spiral immersed in liquid air, they are condensed and retained in the copper tube and are volatilised when the temperature is raised to $-125°$ in the case of thorium emanation and to $-130°$ in the case of radium.—Note on the action of barium hydroxide on dimethylvioluric acid, by M. A. Whiteley. The principal product of this action is isonitrosomalondimethylamide.—The determination of strychnine and brucine in nux vomica, by E. Dowzard. The brucine is determined by colorimetric estimation of the tint produced by the solution of the alkaloidal residue in nitric acid.

Entomological Society, November 5.—The Rev. Canon Fowler, president, in the chair.—Mr. H. J. Elwes, F.R.S., exhibited, on behalf of Mrs. Mary de la Bèche Nicholl, a collection of butterflies made by her in February, March and April in Southern Algeria; also a collection of butterflies afterwards made by her in the Picos de Europa in Spain; the latter collection comprised about 85 species and was made in 25 days. Mr. Elwes remarked that these collections contained several interesting species of Erebia, Lycæna and other genera, and included three species from Algeria not at present represented in the British Museum collection.—Dr. Chapman exhibited, and made remarks on, two butterflies taken last July at Bejar, in West Central Spain, both notable as being very decidedly larger than any forms of the same species recorded from any other locality. He stated that one of them belonged to a form of *Lycaena argus* (the *L. aegon* of the British list). They were taken about one-and-a-half miles east or south-east of Bejar on July 9 and following days.—Mr. R. South exhibited four specimens of a large form of *Cupido minima* (*Lycaena minima*) from Cumberland, sent to the Natural History Museum by Mr. Mousley, of Buxton. He also exhibited, on behalf of Mr. J. H. Fowler, of Ringwood, a series of *Lithosia deplana*, Esp., from the New Forest, showing interesting variations in both sexes, but especially in the females. It was stated that Mr. Eustace Bankes had recently recorded somewhat similar aberrations of the species from the Isle of Purbeck.—Mr. Hamilton Druce exhibited a specimen of *Limenitis populi*, L., caught whilst being chased by a small bird in July, 1901, near Riga, Russia; also a specimen of *Sesamia nonagrioides*, Lefeb., bred from a larva found feeding in the interior of a banana.—Mr. J. H. Carpenter exhibited a gynandromorphous specimen of *Lycaena icarus*, having the coloration of the male on the left side and that of the female on the right side, captured on Ranmore Common, Surrey, in June last; also several aberrations of this species from Ranmore Common and the Isle of Wight. He also showed specimens of *Vanessa antiopa*, bred from German larvæ, including a remarkable aberration in which the usual blue spots on the upper wings were entirely absent.—Mr. H. St. J. Donisthorpe exhibited a foreign specimen of *Quedius suturalis*, lent him by Mr. Keys, of Plymouth, and a British specimen taken by himself at Gravesend in 1891; also for comparison a specimen of *Quedius obliteratus* taken at Plymouth. He said that most of the specimens of, so-called, *Quedius suturalis* in British collections were really *Q. obliteratus*.—Mr. Pickett exhibited a remarkable series of *Angerona prunaria*, the result of four years' inter-breeding between dark males from Raindean Wood, near Folkestone, and light-coloured females from Epping Forest; also unicolorous light orange-yellow males, light yellow females, dark orange males sprinkled with black, and other unusual aberrations.—Prof. E. B. Poulton, F.R.S., exhibited a series of lantern slides prepared from negatives taken by his assistant, Mr. A. H. Hamm, of the Hope Department, and Mr. Alfred Robinson, of the Oxford University Museum. The slides represented a series of the larvæ and imagines of British moths photographed under natural conditions.—Prof. Poulton also showed a representation of the pupa of *Limenitis populi* prepared from Portschinski's figure and description, and explained the highly ingenious hypothesis by which the appearances are accounted for by the Russian naturalist.—Mr. C. O. Waterhouse communicated a paper by Mr. L. R. Crawshay entitled "On the Life-History of *Drilus flavescens*, Rossi."

Zoological Society, November 18.—Prof. G. B. Howes, F.R.S., vice-president, in the chair.—Dr. Henry Woodward, F.R.S., exhibited two photographs of the heads of stags of the red deer (*Cervus elaphus*) bred in New Zealand, lent to him for exhibition by Mr. Lewis Karslake. Dr. Woodward read an extract from a letter from Mr. D. Russell, hon. sec. to the Otago Acclimatisation Society, giving an account of the successful naturalisation of the red deer in New Zealand. Two stags and six hinds had been turned out in 1868, and their offspring now numbered between 4000 and 5000 individuals. The carcases of some of these deer weighed from 500 to 600lb.—Mr. J. L. Bonhote exhibited some hybrid ducks which he had bred during the past summer, and pointed out in what manner the crosses partook of their parent forms. Three of the specimens exhibited were crosses between three species, viz. the Indian spot-billed duck, the wild duck and the pintail, both the parents being themselves hybrids, thus proving, with regard to the species enumerated, that the hybrids were perfectly fertile *inter se*.—Mr. Oldfield Thomas, F.R.S., exhibited and made remarks upon a stuffed male and the skull of a female of the East-African representative of the Bongo antelope, recently described by him as *Boocercus euryceros isaaci*, which had been obtained by Mr. F. W. Isaac in the Mau Forest and presented by him to the national collection.—Mr. Thomas also exhibited, on behalf of Mr. Lydekker, the mounted skin of an adult male of the Peking deer (*Cervus* [*Pseudaxis*] *hortulorum*), recently presented by the president and the Duchess of Bedford to the British Museum. Mr. Lydekker believed that an adult specimen of this fine stag had not hitherto been figured. The specimen was in full summer dress.—Dr. A. Smith Woodward, F.R.S., gave an account of excavations for the discovery of early Pliocene mammalian remains which he had recently made near Concud, in the province of Teruel, Spain. The bones had proved to be very abundant in a bed of freshwater marl, but they were in a much more fragmentary condition than those found at Pikermi, in Greece. He had discovered evidence of Hipparion, Rhinoceros, Mastodon, and of several small antelopes, and exhibited some jaws of the first of these genera.—Mr. F. E. Beddard, F.R.S., exhibited the stuffed skin of an Indian elephant still-born in the Society's menagerie in August last, and made some remarks thereon.—A communication was read from Mr. R. Lydekker, F.R.S., containing a description of the Cabul race of the markhor (*Capra falconeri megaceros*).—Dr. Forsyth Major read a paper on the specimens of the okapi that had recently arrived in Brussels from the Congo Free State. The author stated that these specimens, whilst presenting the same specific characters as the specimens formerly received by the Congo State authorities, showed conclusively that the male was alone provided with horns, and that the mode of their development was the same as in the giraffe. The okapi seemed to be a more generalised member of the Giraffidæ than the giraffe, sharing not a few features of alliance with the Upper Miocene Palæotragus (Samotherium). In several characters, it was intermediate between the giraffe and the fossil forms; but, apart from these, some features were pointed out in which it appeared to be even more primitive than its fossil relatives. These last characters went some way to support the assumption that Africa was the original home of the Giraffidæ.—A communication was read from Mr. G. A. Boulenger, F.R.S., containing an account of a second collection of fishes made by Dr. W. J. Ansorge in the Niger Delta. The species—fifty-six in number—were enumerated, four of them being described as new.—A communication from Dr. A. Günther, F.R.S., contained a final account of the fishes collected by the late Mr. R. B. N. Walker, on the Gold Coast. Several new species belonging to the families Chromidæ, Siluridæ and Cyprinidæ were described.

Anthropological Institute, November 25.—Dr. A. C. Haddon, F.R.S., in the chair.—Dr. C. S. Myers read a paper on anthropometric investigations among the native troops of the Egyptian Army. The investigations were confined to the privates and non-commissioned officers of the Egyptian Army. By permission of the Sirdar, 1005 men in the Egyptian battalion quartered at Cairo and 189 men in the Soudanese battalions at Khartoum and Omdurman were examined. Photographs were obtained of 176 Egyptians and thirty-one Soudanese soldiers bare to the waist; two photographs, one full-face, the other profile, were taken of each individual. In both Egypt and Soudan, the subjects measured had been drawn from a very wide area, extending as far westward as Bornu and Barū, and southwards as far as Uganda. It now remained to determine whether definite differences of type exist among the Egyptians from various regions of the Nile valley and among the tribes of the Soudan; also whether the Coptic (pre-Mohammedan) people noticeably differ from the general Moslem population of Egypt. Before publishing the results of this inquiry, the permission of the Sirdar has to be obtained. The material collected will supply the necessary data to permit of the preparation of a report on the physical efficiency of the Egyptian Army.—The Hon. John Abercromby read a paper on the oldest Bronze-age ceramic type in Britain; its close analogies on the Rhine; its probable origin in Central Europe. The oldest type of pottery in Britain is the "drinking cup," for which it is proposed to substitute the shorter term "beaker." Fifty-three of Thurman's three types were shown. Twenty-five interments were described in which the beaker was accompanied by ancient objects; three with large flint daggers, three with buttons with the **V**-shaped perforation below and five with stone wrist-guards, all of which objects belong to the later Neolithic period on the con-

tinent. None of the objects found with the remaining fourteen interments are of later date than the thin, flat, broad knife-dagger. As no other ceramic type in Britain can show such a pedigree, it is clear that the beaker is the oldest, though before it died out several other types of fictilia came into use.

Royal Meteorological Society, November 19.—Mr. W. H. Dines, president, in the chair.—Mr. F. Campbell Bayard read a paper on English climatology, 1881–1900, which was a discussion of the climatological data printed in the *Meteorological Record* from the forty stations of the Royal Meteorological Society, which have been continuous for the whole of the twenty years. The elements dealt with by the author are:—(1) temperature at 9 a.m.; (2) mean minimum temperature; (3) mean maximum temperature; (4) relative humidity; (5) amount of cloud; (6) rainfall; and (7) number of rainy days. The results form a valuable contribution to the climatology of the British Isles.—A paper by Mr. C. V. Bellamy, on the rainfall of Dominica, was also read. This was in continuation of a former paper on the subject, and dealt with all the available rainfall data for the Island of Dominica. From this it appears that the mean annual rainfall of the island is 110 inches. In the neighbouring island of Montserrat, a remarkably heavy rainfall occurred during the night of November 28–29, 1896, when as much as 20·13 inches fell in the space of six or eight hours.

Cambridge.

Philosophical Society, November 10.—Dr. Baker, president, in the chair.—Notes on a vibration magnetometer, and on the ball-ended magnets of Robison, by Mr. G. F. C. Searle. The comparison of the horizontal components of magnetic fields by the method of vibrations presents no difficulty when each field is so nearly uniform that a vibrating magnet several centimetres in length may be used. But when the fields are far from being uniform, the magnet must be quite short. The magnet must in any case be slender, for unless its length be at least ten times its diameter, the magnetic moment varies appreciably when the field varies, even for fields comparable with that of the earth. A simple magnet 1·5 cm. in length and 0·15 cm. in diameter is in many ways practically inefficient. In the vibration magnetometer exhibited to the Society, the magnet is 1·5 cm. in length and 0·15 cm. in diameter. The time of vibration is increased from 1·4 to 6·3 seconds by attaching the magnet to a pointed plumb-bob the mass of which is about fifty times greater than that of the magnet. The bob also carries an aluminium pointer to magnify the motion; this enables the time of vibration to be very exactly determined. Ball-ended magnets were devised by Prof. John Robison, of Edinburgh, about 1770; the author was led, independently, to the same design.—On cavitation in liquids, and its occurrence in lubrication, by Mr. S. Skinner. If water is run into the space between two lenses, arranged so as to show Newton's rings, and if one of the lenses is rolled on the other, a crescent-shaped cavity is developed when the velocity of rolling exceeds a certain critical value. The cavity fills as soon as the rolling ceases. With more viscous liquids, such as lubricating oils or glycerine, the formation of the cavity is more marked. With colourless liquids, the production of the cavity is observed by taking advantage of total internal reflection or by using sodium light and observing the Newtonian rings formed in the cavity. With deeply coloured liquids, the effect may be observed by transmitted light. Instantaneous photographs have been obtained of the effects with lenses rolling on planes, lenses sliding on planes and in some other cases. The effects are shown to agree with Osborne Reynolds's theory of the viscous origin of friction when copiously lubricated surfaces move over one another (*Phil. Trans.* A, 1886). That the maximum negative pressure occurs at some distance from the point of nearest approach is confirmed by these observations, and it appears that the layer of lubricant which separates the surfaces at the point of nearest approach is thinner than the wave-length of sodium light. Cavities of the same character probably occur in all sufficiently lubricated bearings.—On the coral reefs of Pemba Island and British East Africa, by Mr. C. Crossland. The paper shows that the island of Pemba, though very similar in structure to that of Zanzibar, is of separate origin to the mainland, whereas the latter island is a part of the mainland barrier system. The fringing reef of the east coast of Pemba represents an early stage in the formation of that of Zanzibar, while a barrier reef, also a result of erosion, not of growth, encloses large bays on the west coast which are comparable to the lagoon of the Bermuda atoll. The mainland of East Africa is bordered by both fringing and barrier reefs, both of which are formed entirely of dead rock, in which physical agencies have in some cases produced miniature atolls. Wherever growing coral occurs in the East African region, it is seen that the physical conditions (*e.g.* the absence of big waves) are not such as to allow the formation of typical reefs. Finally, some observations on the conditions favourable to coral growth were given, which conditions are present round an oceanic atoll to a much greater degree than near a continental area.—On the theory of aggregates, by Mr. A. N. Whitehead.

Paris.

Academy of Sciences, November 24.—M. Albert Gaudry in the chair.—The velocity of light and the solar parallax, by M. Perrotin. An account of experiments at the Observatory of Nice on the velocity of light. Fizeau's method was used, the total distance traversed by the light being 92 kilometres. As the emission telescope, the 72 cm. objective of the Observatory was utilised, with a 38 cm. objective as collimator. The mean result of 1109 observations was 299,860 kilometres per second in a vacuum. By combining this with the observations on the planet Eros, from which a value of 8″·805 was deduced for the solar parallax, the coefficient of annual aberration was found to be 20″·465, the exact number adopted by the International Astronomical Conference of 1896 at the instance of MM. Lœwy and Newcomb.—On the origin and geographical dispersion of *Lagomys corsicanus*, by M. Ch. Depéret.—Report on the work accomplished by the Brazilian Commission, under the direction of M. Cruls, on the exploration of the principal sources of the Javary, and for the determination of the geographical co-ordinates of several points in this region at points common to Peru, Brazil and Bolivia, by M. Lœwy.—Observations of the sun made at the Observatory of Lyons with the Brunner 16 cm. equatorial during the third quarter of 1902, by M. J. Guillaume. Tables are given showing the number of spots, their distribution in latitude and the distribution of the faculæ in latitude.—On monodrome functions with an isolated essential singular point, by M. Edmond Maillet.—On an extension of the notion of periodicity, by M. E. Esclangon.—On an automatic carburettor for explosion motors, by M. A. Krebs. A theoretical investigation as to the manner in which the area of the orifice air should vary with the pressure of the air and the height of the petrol in the reservoir. Following the indications thus obtained, an apparatus has been constructed in which these conditions are fulfilled, and it has been found that the velocity of the motor can be varied suddenly between very wide limits, an absolutely constant gas mixture being obtained.—On the construction of electrodiapasons with long variable periods, by M. E. Mercadier.—On the ionisation of a salt flame, by M. Georges Moreau. The ionisation of the salt flame was found to decrease according to an exponential function of the distance between the electrodes, and the conclusion is drawn that the unipolar conductivity of a saline vapour is analogous to that of a mass of hydrogen surrounding an incandescent carbon filament, or that of a gaseous mass in contact with a metal illuminated by ultra-violet radiations.—Some observations on uranous oxide, by M. Œchsner de Coninck. Uranyl bromide, ignited in a current of air, loses its bromine, thus differing from the behaviour of the corresponding chloride.—On the combinations of the complex cyanides with fatty amines, by M. P. Chrétien. A study of the salts obtained by the action of hydroferrocyanic acid upon the primary iso-amylamines.—A method for the estimation of glycerol in wine, by M. A. Trillat. The method is based upon the solvent powers of pure acetic ether for glycerol. The glycerol extracted is much purer than that obtained by the usual alcohol-ether method.—On the structure of the muscles of *Anomia ephippium*, by M. Jobert.—On some new or slightly known forms of Rhabditis, by M. Aug. Michel.—The theory of phytons in Gymnosperms, by M. G. Chauveaud.—On the mode of vegetation and reproduction of *Amylomyces Rouxii*, the fungus of Chinese yeast, by M. J. Turquet.—The actual production of native sulphur in the subsoil of the Place de la République, in Paris, by M. Stanisla, Meunier. In the course of the excavations for a railway tunnels native crystallised sulphur has been found in a black clay. Reasons are given for supposing that this deposit has been formed during the last two centuries.—On the general theory of the action of some diastases, by M. Victor Henri. Two hypotheses are examined; supposing that a portion of the ferment

combines with a part of the body undergoing hydrolysis, another part combining with a portion of the products of hydrolysis. It may be supposed either that it is the non-combined part of the ferment which acts upon the bodies to be split up, or, on the other hand, that the unstable compound formed is itself decomposed, regenerating a part of the ferment. It is remarkable that both these hypotheses lead to the same law. Experiments are given showing the action of invertin upon saccharose alone and mixed with invert sugar, and of emulsin upon salicin.

NEW SOUTH WALES.

Royal Society, October 8.—Prof. Warren, president, in the chair.—Occurrence of the mineral gadolinite at Cooglegong, Pilbarra District, West Australia, by Mr. Bernard F. Davis.—Pot experiments to determine the limits of endurance of different farm crops for certain injurious substances, part i. (wheat), by Mr. F. B. Guthrie and Mr. R. Helms. The authors describe experiments to test the effect upon the growth of the wheat-plant of certain substances occasionally found in the soil and in manures, and known when present in excessive quantities to act as plant poisons. The following table summarises the principal results obtained.

Effect upon germination and subsequent growth of wheat of different percentages of injurious substance in the soil.

COOPERATION AMONG INSTRUMENT MAKERS.

L'Industrie Française des Instruments de Précision. Catalogue publie par le Syndicat des Constructeurs en Instruments d'Optique et de Précision.

Microscopes and Microscopical Accessories. Carl Zeiss, Jena; *Physical Apparatus*, Max Kohl, Chemnitz; *Physikalische Apparate*, Ferdinand Ernecke.

THE German catalogue of scientific apparatus at the Paris Exhibition has been frequently mentioned in the pages of NATURE, and its value to students of physics has been noted.

The first work under review in the present article is a consequence of its publication. It is a catalogue of French apparatus of great interest in itself and of real value to the man of science in that it enables him to obtain information in a small compass as to instruments of French construction.

The arrangement differs in some respects from that of the German catalogue, on which it is avowedly based. The object of the latter was to give a complete view of German trade and manufacture; hence the catalogue was arranged in subjects, the apparatus in each subject being grouped under the makers' names; the French catalogue is arranged alphabetically under the makers' names. An index "Table des Specialités" enables the reader to find out readily which of the numerous firms in the catalogue make any special class of apparatus and to refer to the descriptions of their products. For most purposes, the German plan seems more convenient. For a man wishing to buy a spectroscope, it is simpler to have all the spectroscopes grouped together; the plan, however, does not serve to call marked attention to the whole output of any one large firm, and it is natural for a society of instrument makers to arrange their joint catalogue according to the French pattern.

It is not easy in a review to give a full account of the catalogue; it covers some 270 quarto pages, it is clearly printed and well illustrated. The long list of names it contains reminds us what science owes to the skill and workmanship of French mechanicians; it is impossible to turn over the pages without recognising names which are honourably known wherever science has penetrated, and apparatus which has aided and rendered possible some of its greatest discoveries. One name we miss, that of R. König, now no longer with us, who will live, through his acoustical apparatus, as a genius of construction.

The introduction by Cornu, which must have been one of his last pieces of work, adds to the value of the book. M. Cornu gives an interesting history of the development of scientific instruments in France, and of the close alliance between the man of science and the instrument maker from early times up to the present day, and then, noting how instruments of precision have become part of one's daily life, draws attention to the necessity for continued close connection between science and the commercial side of an industry if that industry is to flourish.

The example of Germany has lessons for France as well as for us in England, and mechanical tools introduced in America have become a necessity in French workshops no less than in English. The French instrument-making industry feared for a moment a dangerous rivalry and the diminution of its own trade through the advance of new comers proclaiming themselves so fully equipped.

The catalogue is in part the outcome of this; it helps to show, as M. Cornu claims, that the French industry has nothing to fear from its foreign rivals.

"To complete its successful preparation for the struggle, it is only necessary to adopt, in addition to what it has done, the powerful weapons of association and discipline —a discipline voluntarily accepted in view of general interests; then an intelligent union will lead all efforts to converge towards one common end instead of wasting them in those barren struggles which the thirst after immediate interests provokes in short-sighted minds."

We in England have no Association of Instrument Makers and no catalogue of instruments of precision. The Optical Society, it is true, is doing its best to strengthen the position of opticians, but it is far from covering the whole field.

Does not the fact that our French colleagues have followed the example set by Germany give us food for reflection, and lead us to inquire whether association and discipline might not be helpful to us also?

And this query is pressed home by three recent catalogues of scientific apparatus which have been issued by German firms; the first in English, the second in English, French and German, the third in German. Messrs. Zeiss's list deals with their microscopes, and is most complete. As usual with their lists, it is fully illustrated, while the information about the instruments is given in a convenient form. Details as to the lenses are tabulated, and it is easy to select the particular combination of object-glass and eyepiece most suitable for any desired end. The set of apochromatic objectives is very complete; lenses of 2 and 3 mm. focus and 1·4 numerical aperture are on the market; these, it is stated, are made of permanent glass. The list is an object lesson of the results technical art and skill can produce when resting on a basis of sound scientific investigation.

Messrs. Max Kohl, whose agents in this country are Messrs. Isenthal and Co., have issued a catalogue of nearly 700 pages. They supply almost everything required for teaching purposes in a physical laboratory. Their goods are well known, and the list affords striking evidence of the progress of science in education, in Germany at any rate, if not here. Much of the apparatus is extremely well arranged for the purpose for which it is designed, and the list is one which is sure to be of value in every physical laboratory.

Messrs. Ernecke's catalogue contains an account of their goods, with illustrations of a high class. Though smaller than that of Max Kohl, it commands attention by the wide range covered and the general excellence of the get up. Lists such as the above must prove of advantage to German trade in all countries of the world and be powerful aids in international competition. Their convenience is obvious. We in England specialise more; we go to one firm for resistance boxes, to another for

telescopes, and have nothing exactly corresponding to a vast emporium such as that of Max Kohl. All the more reason, therefore, for the association and discipline urged on his French colleagues and co-workers by Cornu.

R. T. G.

AMERICAN FOOD AND GAME FISHES.

American Food and Game Fishes: a Popular Account of all the Species found in America North of the Equator, with Keys for Ready Identification, Life Histories and Methods of Capture. By David Starr Jordan and Barton Warren Evermann. Pp. l + 573; illustrated with coloured plates and text drawings, and with photographs from life. (London: Hutchinson and Co., 1902.)

DRS. JORDAN AND EVERMANN, who have recently enriched science by the publication, under the auspices of the Smithsonian Institution, of a great work in four volumes describing in detail the 3300 species of fishes distinguished by them in North and Central America, reviewed not long ago in the columns of NATURE, have now prepared another book, intended to

"furnish that which well-informed men and women, and those who desire to become well informed, might wish to know of the food and game fishes which inhabit American waters."

This book, teeming with interest from the full accounts, presented in a charming manner, of the habits, distribution and uses of the more important forms from the point of view of the angler, has been lavishly got up in America. The coloured pictures, as well as the photographs taken from life with marvellous success by Mr. A. Radclyffe Dugmore, could not be surpassed in excellence, and the numerous "process-blocks" which have already appeared in various American publications will, thanks to the perfect accuracy with which the fishes have been delineated, greatly facilitate identifications. Authors and publishers are to be congratulated on the production of such a book, which will undoubtedly have the effect of enlisting a more scientific interest in fishes on the part of many who have hitherto looked upon them as mere objects of sport or curiosity, and to whom the use of the more technical treatises on the subject would be distasteful. In deference to such readers, the systematic aspect has been reduced to the narrowest limits that appear compatible with the proper recognition of the numerous genera and species dealt with. It is to be hoped that not a few whose interest is sure to be awakened by a perusal of this charming book will later turn to the more technical work by the same authors, and improve their knowledge through a study of the relationships existing between the various families of fishes, which are here merely defined without any allusion to the higher groups into which they fall.

American taxonomists have always shown a particular predilection for reducing all divisions of the system to the narrowest possible limits. This tendency is carried to the extreme by Messrs. Jordan and Evermann, who inform us in the introduction that not only the lampreys and hags are to be excluded from the class Pisces, but also the sharks and rays, the lung-fishes and Polypterus, which they regard as only fish-like creatures, fishes in the broad sense of the term, but not "true fishes," and are therefore excluded from the work. Ganoids, on the other hand, are still maintained among fishes proper. In conformity with this method of excessive multiplication of systematic divisions of all grades, the various forms of Salmonidæ which are usually regarded as subspecies, such as the land-locked salmon and the varieties of *Salmo clarkii*, *gairdneri* and *fontinalis*, are all dealt with as distinct species—twenty-six species instead of the four admitted by the same authors in their previous work. True, a few pages before, the authors pertinently remark that

"The non-migratory species (subgenus Trutta) occur in both continents, are extremely closely related and difficult to distinguish, if, indeed, all be not necessarily regarded as forms of a single exceedingly unstable and variable species. The excessive variations in colour and form have given rise to a host of nominal species. European writers have described numerous hybrids among the various species of Salmo, real or nominal, found in their waters. We have thus far failed to find the slightest evidence of any hybridism among American Salmonidæ in a state of nature. Puzzling aberrant or intermediate individuals certainly occur, but such are not necessarily hybrids."

Bearing in mind the authors' tendency to excessive multiplication of species and higher divisions, it is not a little surprising to read in the introduction that the "true fishes" of the whole world are estimated at only 12,000 species, arranged in about 200 families. A careful computation which has recently been made by the reviewer, applying somewhat different canons of classification, has resulted in numbers that are not very different, viz. 11,200 for the species and 160 for the families. The number of species in the American authors' estimate is even far below that given in the article "Ichthyology" in the supplementary volumes of the "Encyclopædia Britannica," viz. 17,000.

The usefulness of the work is enhanced by special chapters on the external characters of fishes from the descriptive point of view, on fly-fishing (by Mr. E. J. Keyser), a glossary of technical terms, and an artificial key to the families of American food and game fishes.

The copy received for review bears the mark of a London publishing firm. But the identical book was issued in May last by Messrs. Doubleday, Page and Co., at New York.

G. A. B.

HUMAN ANATOMY.

Text-Book of Anatomy. Edited by D. J. Cunningham, F.R.S. Pp. xxix + 1309; 824 wood engravings from original drawings. (Edinburgh: Pentland, 1902.)

AT the present time the human anatomist tries to sit as comfortably as he may on the two stools of science and practice. It must be admitted that few do it with success. While his posture evokes the indulgent smile of the man of science, the professed zoologist and morphologist, the man of practice, the surgeon and physician, regards it as altogether unprofitable and impracticable. To reconcile the views of these two contending factions, to make the theory of anatomy assist in its practical application to the sick and the facts of

anatomy illumine the laws of mammalian morphology, is the first and chief difficulty of anyone who now or afterwards undertakes the preparation of a text-book on human anatomy. No living anatomist is likely to be more successful in overcoming this difficulty than Prof. D. J. Cunningham, who is deservedly held in the highest esteem by the surgeon and physician, as well as by the man of science. While admitting that Prof. Cunningham has been more successful than any one of his predecessors, one rises from the study of this work with the feeling that, in spite of rapid improvement, it will take decades of progress to make the theory of anatomy fit its facts as a glove does the hand.

Not a single decade has passed during the last two centuries without someone proclaiming from the house-tops that at last the whole field of human anatomy is explored and finished, and yet the annual output of new research has continually increased. The manner in which this work is produced is evidence of the rapid growth of the subject. It is no longer possible for one man to be intimately acquainted with the more recent work or to supply first-hand information in each of the many departments into which human anatomy has been subdivided, and hence the necessity for a collective effort. Works of reference like the English Quain, the French Poirier, the German Bardeleben, necessarily demand the combined services of specialists, but here, even in a work designed to meet the needs of candidates for a pass degree, the same necessity has been felt. The editor has been fortunate in the selection of his collaborators. To Prof. Young, of Owens College, and Prof. Robinson, of King's College, London, have been assigned the sections on embryology and the vascular system; to Prof. Thomson, of Oxford, that on osteology; to Prof. Paterson, of Liverpool, the muscular and nerve systems; to Dr. Hepburn, of Edinburgh University, the section on joints; to Prof. Howden, of Durham University, the section on the organs of special sense; to Prof. Birmingham, of Dublin, the organs of digestion; to Prof. Dixon, of Cardiff, the urinogenital system; to Dr. Stiles, the section on surgical anatomy; while the editor himself undertook the central nervous system. It may be said at once that each contributor has given, not only the best that is known, but has also made original contributions to his particular section. Some of the sections, such as those on the nervous system, the alimentary system and embryology, gave their authors a greater opportunity than did others, and these opportunities have not in any single case been allowed to slip by.

There is a unity in the work which may be explained by the fact that all the contributors, with one exception, are pupils of the veteran leader of the Edinburgh anatomists, Sir William Turner, to whom the book is most worthily dedicated. This work has all the merits and also all the defects of the Edinburgh school. There are the full and lucid descriptions of the important things, but there is also an over-strenuous endeavour to be thorough by the introduction of masses of unimportant or irrelevant detail. Turn, for instance, to the description of the spermatozoon, and it will be found that the medical student is expected to master more than fifty details concerning its structure; or turn to the descriptions of a bone, a muscle or an artery, and the same crowding of detail will be found. A student who thoroughly prepares himself from this work will present himself to his examiners loaded with more than 60,000 anatomical facts, 75 per cent. of which will appeal to his memory more than to his intelligence, and only a small percentage of which will be of use to him in the practice of his profession. It is a primary defect of the Edinburgh school that, owing to its detachment from the hospitals, it has come to regard the study of anatomy as an end in itself instead of being only the scaffolding on which a student has to lay his knowledge of physiology. On the combined basis of anatomy and physiology he has subsequently to build his knowledge of pathology, surgery and medicine, and all the efforts of the anatomist and physiologist must be bent so as to reach this end. The student, when he comes to build out his mental picture of the circulation, respiration and locomotion of the human body, will find that this work will afford scarcely a better anatomical scaffolding than older and less complete works.

One feels that Prof. Cunningham has let slip an opportunity that occurs to a man only once in a century. With such a powerful syndicate of anatomists behind him he could have disregarded the prejudices of examiners, relegated thousands of useless anatomical details to the limbo of oblivion and made his subject once again live. That he has not done so shows that the principle on which present systems of anatomy are designed meets with his deliberate approval, and it is on those broad lines that most thinking men will join issue with him.

During his study of this work the reviewer has laid it side by side with Bell's "Anatomy," another triumph of the Edinburgh school, but of a century ago. The opinion has been forced on him that the design of the older book is the better of the two. All through Bell's pages, in spite of some crude theories, inaccurate facts and passing personalities, anatomy is made to coquet with physiology and morphology, and all three are invariably made to serve as handmaidens to the surgeon and physician. The ideal treatise of human anatomy will be produced by the man who accepts the principles of the anatomists of the beginning of last century and applies them to the facts at the disposal of anatomists at the beginning of the present one.

The illustrations of this work are all well designed and artistically finished, but the poorness of its binding and its narrow margins, which give it a general appearance of meanness, are out of keeping with the high standard of its contents and the artistic demands of the present day medical student.

A. KEITH.

DIFFERENTIAL CALCULUS FOR BEGINNERS.

Differential Calculus for Beginners. By Alfred Lodge, M.A., with an Introduction by Sir Oliver J. Lodge, D.Sc., F.R.S., LL.D., Principal of the University of Birmingham. Pp. xxv + 278. (London: George Bell and Sons, 1902.) Price 4*s*. 6*d*.

PROF. ALFRED LODGE is so well known among mathematicians as an authority on the teaching of geometry and kindred subjects that the addition of his brother's name to the title-page may appear superfluous.

The introduction by the latter contains a brief statement of the uses and purposes, not only of the differential calculus, but also of the integral calculus and of differential equations. The present volume, however, deals exclusively with the differential calculus, and that only so far as it refers to functions of one and two variables. A notable and important exception to this limitation, however, occurs in the chapter on successive differentiation, where the notion of $D^n y$ naturally leads to that of $D^{-n}y$, in other words, the nth integral of y. Here, however, the notation D^{-n} is alone used, the familiar "F-hole of a violin" being conspicuous by its absence. Probably the latter symbol might advantageously be eliminated from our mathematical notation altogether, were it not for the important difference between differentiation and integration introduced by the appearance of the inevitable "constant of integration" which leads to the further notion of "definite integrals."

The amount of attention given to graphs will be welcomed by the great majority of teachers, and chapter vi., which deals with the application of graphic methods to the approximate solution of equations, is an important feature which ought certainly to occur at some stage or other of an ordinary mathematical curriculum, and may probably be inserted here quite as well as elsewhere. The feature which is most calculated to arouse criticism is the adoption of the method of differentials as the basis of the whole work. The author states that he has found this method most useful and helpful to the student of physics and mechanics, but it has the great disadvantage of throwing into the background something which is very important, namely, the notion of a limit. In examinations there has recently been a tendency on the part of candidates, when asked to find from first principles the differential coefficient of sin x, to send up the following answer :—

$$\frac{d(\sin x)}{dx} = \frac{\sin(x+dx) - \sin x}{dx} = \frac{\sin x + dx\cos x - \sin x}{dx}$$
$$= \frac{dx \cos x}{dx} = \cos x.$$

Even this might be excused if the candidates showed an intelligent appreciation of the meaning of what they were writing down, but as soon as they are asked to differentiate x^x, log sin x, or anything which is not in the book, they exhibit hopeless ignorance, thereby proving conclusively that the stock differentiations have been merely written down by rote.

There is no doubt a tendency on the part of another class of writer to rush to the opposite extreme by making the student read long discussions on continuity before introducing him to the notation of the calculus. But cannot a happy mean be found by introducing the notions implied in the relation $dy = f'(x)dx$ *immediately after* the principal algebraic and transcendental functions have been differentiated by means of the method of limits? Apart from this matter of opinion the book appears to be excellent.

We are glad to see the author does not relegate Taylor's and Maclaurin's theorems to the end of the book. In a logical treatment, that might possibly be their proper position, but the postponement would prevent many readers from acquiring an intimate familiarity of what are probably the most important theorems in the whole of the calculus. G. H. B.

GALL-INSECTS.

Monographie des Cynipides d'Europe et d'Algérie. By l'Abbé J. J. Kieffer. Vol. I. Ibalynæ et Cynipinæ. With 27 plates. Pp. vii + 687. (Paris: Hermann, 1897–1901.) Price fr. 40.

THE present work is a portion of the great series of monographs commenced by the late E. André, under the title of "Spécies des Hymenoptères d'Europe et d'Algérie," by himself, his brother and other specialists, among whom are the Rev. T. A. Marshall and the Abbé Kieffer. The character of the work is well known to all hymenopterists, and in this regard we need only say that another volume will complete the Cynipidæ, including the parasitic subfamilies Allotriinæ, Eucoilinæ and Figitinæ, and will also include the families Evaniidæ, Stephanidæ and Trigonalidæ, and full systematic and synonymic catalogues and indices to both volumes, the first volume containing only an index of families and genera, and a table of contents.

In addition to the systematic portion of the work, the structure, metamorphoses, broods, galls, parasites, biology, bibliography, classification, geographical distribution, &c., of the Cynipidæ are discussed at considerable length; and the author mentions in his preface that though, when he undertook this work in 1896, few or no Cynipidæ were known from any of the more southern countries of Europe or from Algeria, he has now obtained, through the kindness of various contributors whom he mentions, considerable information on these countries, though much of it reached him too late for the first volume and will have to be deferred to the supplement in vol. ii.

Notwithstanding the insignificant appearance of the Cynipidæ, on which the Abbé remarks, they are of extreme scientific interest on account of the alternations which the various broods present of winged and wingless, and sexual and sexless, individuals at different times of the year, in which respect they have much resemblance to the Aphidæ, though the Cynipidæ, unlike the latter, are seldom or never to be regarded as destructive insects, one reason for which may be that the Cynipidæ (or at least certain species) are liable to the attacks of an inordinate number of small parasitic Hymenoptera, chiefly belonging to the Chalcididæ, so that an entomologist may breed a great variety of Hymenoptera from (say) a large quantity of galls of *Cynips kollari*, without obtaining a single specimen of the original species which formed the galls.

Although the insects themselves are inconspicuous, their galls are conspicuous enough, and some of the large fleshy eastern galls on oaks, such as the Apple of Sodom, resemble brightly-coloured fruit; while the moss-like galls, such as the bedeguar on the wild rose, are likewise very pretty objects. One peculiarity of these insects is that a considerable number of the species are attached either to oaks or roses, though some few are met with on other trees. They are also among the few insects which yield products of great value to the human race, the most important of which, of course, is ink; but various galls have been, or are still, used for illumination, for tanning, in medicine, for chemical purposes, and in the case of a few species, even for food.

Though some of our earlier hymenopterists, such as

Haliday and Walker, paid some attention to Cynipidæ, others, such as Stephens and Smith, almost entirely neglected them; and it was not until Mr. P. Cameron published vols. iii. and iv. of his "Monograph of the British Phytophagous Hymenoptera" that we had a satisfactory account of our British species. On the continent, more had been done by Mayr, Adler and others, and now the Abbé Kieffer has furnished us with a full account of the European and Algerian species of these interesting but still somewhat neglected insects; and although every monograph or catalogue always helps to make itself incomplete by stimulating the activity of all observers who are sufficiently interested in the subject to take up or to continue the study, yet the book may reasonably be expected to hold its place as the leading authority on the subject for many years to come. W. F. K.

OUR BOOK SHELF.

Chemisches Praktikum. 1 Teil. Analytische Übungen. By Dr. A. Wolfrum. Pp. xviii + 562. (Leipzig: W. Engelmann, 1902.) Price 10*s.* net.

The object of the author is to present a course of practical instruction in analytical chemistry on a technical basis. It is intended that the student shall be confronted throughout his course of work with the technical application of the principles and methods which he makes use of in the laboratory. The author hopes by this means to improve the training of the student whose aims are directed towards chemical work in the arts and manufactures.

The subject-matter is divided into three sections, under the headings qualitative, quantitative and technical analysis. In the first section, the ordinary reactions of the metals and acids are given, ionic nomenclature being employed. The rare metals are dismissed by a consideration of thorium and cerium, these alone in the author's opinion being of sufficient technical importance to merit discussion. The qualitative analysis of organic substances is then treated, the reactions for the most important organic radicals being given. The section concludes with a long list of important organic compounds for which the special tests are given, as well as directions for ascertaining the presence of the most frequently occurring impurities.

In the section on quantitative analysis, the order of treatment is, gravimetric estimation of the metals and acids, elementary analysis of organic compounds, volumetric analysis and estimation of the most important atomic groups of organic compounds. Twenty pages are devoted to the methods of determining molecular weights of organic compounds and fifteen to gas analysis, but, singularly enough, not a single diagram is appended to illustrate the special apparatus used in operations with gases.

Under technical analysis, which forms the subject of the last 200 pages, is discussed the analysis of water, fuels, ores and metallurgical products, products of the chemical manufacturing industries, artificial mineral colouring matters, artificial manures, lime, cement, clay, raw materials and products of the sugar industry, ethereal oils, aniline colours and products used in the manufacture of these colours.

The book, as will be seen, contains a wealth of material. It is doubtful, however, whether such a work could be placed with good results in the hands of the average student of chemistry. The amount of material accumulated by the author within such a small compass is so great that the efficiency of the book as a working guide for the student must necessarily suffer. All experienced teachers are aware that a book which the average student is to use in his daily work in the laboratory must contain full working details, and the "Chemisches Praktikum" does not.

As a reference book, however, it will without doubt be found very useful in the laboratory, and for such a purpose can be warmly recommended. H. M. D.

The Coal-fields of Scotland. By Robert W. Dron. Pp. vi + 368. (London: Blackie and Son, Ltd.) Price 15*s.* net.

Numerous descriptions have been published of the Scottish coal-fields from the time of Ball, Milne and Landale to our own day. Most of these, however, have been scattered through the volumes of scientific journals or published in official reports which, as a rule, have been badly printed, expensive, and insufficiently made known to the public. By far the most important contributions to the subject are those to be found in the maps and memoirs of the Geological Survey. These publications contain a storehouse of information; they were the first, and are still the most detailed and complete, review of the whole geological structure of the coal-fields. The maps present a graphic picture of the disposition of the coal-seams and the extent to which they have been dislocated and folded. The memoirs furnish a large amount of information which could not be embodied in the maps, and both taken together form the basis on which all subsequent descriptions must rest. The progress of development has led to the opening of some new fields and to the exhaustion of others, since the appearance of the Survey publications, but we understand that arrangements have been made for an official re-examination of the coal-fields and the preparation of new editions of the maps. The work of the Survey will thus be brought up to date, and will maintain the high position which it has always held.

Without these official maps and memoirs, Mr. Dron could not have produced the volume which he has just published. He acknowledges, in his preface, in a general way that he has freely utilised "all available sources of information, including the publications of the Geological Survey." It would have been well, however, had he made more specific acknowledgment of his obligations. No one who is not familiar with the subject would suspect from his chapters how deep his indebtedness is all through the book. The occasional allusions to the Survey work seem strangely inadequate in comparison with the fulness of his references to private individuals of whose assistance he has availed himself. The maps, for instance, with which he embellishes his book are reduced (not very satisfactorily) from those of the Geological Survey, but there is no reference to the source from which they are derived. The volume, though it has no originality, supplies a convenient summary of what is at present known regarding the coal-fields of Scotland, and may be useful as a popular handbook of the subject.

A Glossary of Popular, Local, and Old-Fashioned Names of British Birds. By C. H. Hett. Pp. vi + 114. (London: H. Sotheran and Co., 1902.) Price 1*s.*

To the last edition of his "Bird Notes," the author appended a glossary of synonyms of the British species. The present little volume is an amplification of that glossary, and appears to be as nearly complete as possible. The work commences with a classified list of the British species (in which we notice that the author is a conservative in the matter of nomenclature), and then follows the glossary. It should enable amateur ornithologists residing in country districts to identify all the local birds without difficulty. R. L.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Suggested Nature of the Phenomena of the Eruption of Mont Pelée on July 9. Observed by the Royal Society Commission.

ALTHOUGH Dr. Anderson and Dr. Flett were able, at the largely attended meeting of the Royal Society on November 20, to add little to what they had published in their preliminary report three months ago, beyond exhibiting the very full and excellent series of photographs of the affected regions of the Soufrière and Mont Pelée eruptions, they succeeded in exciting renewed interest in the problem of the nature of that eruption of Mont Pelée on the evening of July 9, which they had the exceptionally good fortune to witness under most favourable conditions. The photographs and perfect description of this particular outburst give it an unsurpassed value as a contribution to the scientific history of volcanoes, and the Royal Society has therefore the greatest reason to congratulate itself upon the success—a success almost beyond the most sanguine expectation—of its commission to Drs. Anderson and Flett to visit the scene of these eruptions.

We can now hardly hope that any fuller knowledge of the nature of an eruption of the kind witnessed by these geologists will be forthcoming through future observations. What is now to be done in order to clear up what remains obscure is experimental work in the laboratory. To me it seems that only one point requires investigation before we shall have a definite conception and understanding of the phenomenon at the base of such outbursts as those in the West Indies, as well as that of the Bandaisan eruption, or rather explosion, in Japan, closely similar to them in its essential features.

From the text of the published report, modified a little in the accounts given at the meeting, we know that, after spasmodic bursts of steam, dust, and stones, and discharges of torrents of water and mud, the climax of the eruption came as the welling-up in the crater and overflow, like that of a liquid, of red-hot dust, which descended the mountain side, at first relatively slowly, but with ever-increasing velocity, like an avalanche of snow. This avalanche of incandescent sand was accompanied by a dense cloud, black as night, which soon concealed it from view and swelled out in convolutions with terrible energy until it reached perhaps one mile high and two broad. After this, it ceased to enlarge and gradually lost its dense blackness through ash settling down and leaving nothing visible but white steam.

There was, therefore, (1) a flow of incandescent sand down to the sea, mainly by gravitation, but with a velocity apparently surpassing that of a torrent of water; and (2) the expanding motion of the superincumbent, black cloud, together with its rapid motion along the course of the stream of sand, *from which it never lifted.* Just after the overflow of sand from the crater, there must have been an enormous outrush of steam and, perhaps, other gases, and this will have had some effect in driving the cloud through the air; but the progressive formation and the appearance of the cloud forbid the belief that this effect could have been considerable. That the cloud enlarged upwards rather than laterally was due to its consisting of heated steam, for although the dust which it carried with it will have impeded the velocity of its expansion, it will not have lessened its extent.

There can be only one conclusion drawn as to the cause of the free motion and rapid rush of the torrent of sand and of the swelling, convoluting cloud, and that is the continuous evolution of water vapour from every particle of the moving hot sand. Possibly some other gas may also have escaped, but if so only in relatively small quantity, as otherwise the water vapour would not so easily have condensed and become visible. Violent friction between the issuing steam and the solid particles may sufficiently account for the extensive electric discharges. The continuous escape of this water from the particles of the hot sand, at such a high temperature, even though in small quantity, would surround every particle with a compressed atmosphere of steam sufficient to keep it apart from all others, and thus produce a quasi-liquid mass which, on account of the density of the sand, would gravitate strongly and at the same time would, by virtue of the interstitial compressed steam preventing all rubbing together of solid particles, give the mass its marvellous mobility. That this would be so is easily borne out by facts familiar to the chemist and physicist. One of these was, indeed, brought up by Sir William Ramsay in the discussion which followed upon the reading of the papers, namely, the behaviour of precipitated silica when heated, which, however, he attributed to a movement of particles in gases similar to that of Brownian movements of particles in liquids. When any fine dust or powder, which is non-coherent whether cold or hot, gives off sufficiently fast a gas or vapour when heated, it will, when smartly heated, swell up and become mobile, sometimes almost as mobile as liquid ether, keep a horizontal surface when its containing-vessel is tilted, and admit of being poured like a liquid into another vessel. Because of its frequent presence in the work of inorganic chemical analysis, precipitated silica is, perhaps, the most widely known example of this behaviour. In ordinary circumstances, the silica acts in this way almost wholly in consequence of its continuing to liberate up to even a blowpipe heat the water always present in some form of combination with it. Probably, too, it and all such light powders owe for a moment part of the movement of their particles from each other merely to the rapid expansion of the air in the interstices of the powder when the containing vessel is quickly heated, but the escape of hygroscopic or other moisture is obviously the principal cause. When the silica is kept steadily heated, it loses most of its mobility. Other hygroscopic or vapour-condensing powders behave similarly; very finely divided charcoal powder is generally a good example; magnesia alba is another, which gives out both carbonic acid and water.

Light bodies are naturally best fitted for the observance of this phenomenon, but manganese binoxide when evolving oxygen shows it, and even platinum black will throw up dust and enlarge. Indeed, it is a common phenomenon for a slightly coherent powder suddenly heated in a platinum crucible to float in motion as a moulded mass in an atmosphere of gas generated from itself by the hot walls of the crucible. Not inapposite instances of the power of escaping vapour to hold up bodies is that familiar phenomenon of liquid water or alcohol assuming the spheroidal state, that is, rolling about on a hot plate without touching it, being couched on a bed of its own continuously evolved vapour. Where experiment is now wanted is to find out what andesitic minerals will, under great pressure, combine chemically or physically, but intimately, with water at a red out heat and then retain it sufficiently when the pressure is released for an appreciable though short time to elapse before the regeneration of the steam is ended.

A modification of the explanation here given suggests itself which would do away with the necessity for the existence of such combinations of water with rock materials. It is that as the incandescent sand flowed over the soil, it generated the steam from the damp earth or hydrated rocks beneath it in such quantity as to buoy up the sand from the soil and separate its particles. In accordance with this view would be the observation that the hot sand visibly (that is, without obscuring cloud) poured over the lip of the crater and then as it flowed down obscured itself in cloud. On the other hand, the escape of gas or vapour caused by cooling is not an unknown phenomenon, while against this view is the difficulty to explain when holding it the production of the sand within the crater. Drs. Anderson and Flett speak of the dust as lava blown to pieces by the expansion of the gases it contains. I would suggest that the production of the sand just in that way is inconceivable; for if the lava had been molten, it would have been scattered in drops and vesicles in all directions, and only if solid would it have become dust, while in either case it would not have remained as a mass of sand, but have been scattered to the winds. The production of sand or dust, if it really was produced in the crater, will have been a disintegration of rock masses by the pressure diffused through them of the condensed water, with which they were impregnated and perhaps combined, a disintegration leading up to the falling to dust of the masses while they were still under sufficient pressure to prevent scattering.

The strong escape of steam from the sand would, of course, carry up much of the dust with it and thus constitute the black cloud, while its cauliflower-like expansions were apparently only an exaggerated form of what is to be seen over a seething cauldron or a stream of boiling water. The Paradox of the Piano Player.

WHEN a number of notes in different parts of the keyboard of a pianoforte are struck by means of levers actuated by a common pneumatic pressure, it appears to be the universally prevailing belief that the only variations possible are those in which the whole chord is made to sound louder or softer by increasing or decreasing the pressure. It is commonly regarded as an impossibility to vary the *relative* intensities of the sounds produced by the various notes so as to make, *e.g.*, the bass parts sound louder and the treble softer, or *vice versâ*.

On the other hand, dynamical considerations suggest that the intensities of the sounds excited in the different strings of the piano depend, not only on the total pressure applied to the mechanism, but also on the way in which this pressure is made to vary during at least part of the interval from the instant at which the key is first touched to the instant at which the hammer leaves the strings. A short, sharp impulse suddenly cut off should produce its greatest effect on the notes of higher pitch, while a heavy, sustained or increasing pressure should make its effect most marked on the lower notes of the instrument. During the last few months, I have given considerable attention to the practical application of this theory, and the effects which I find it possible to produce, provided that the accentuation is performed at exactly the right instant of time, are most remarkable. The treble or bass parts may be made to stand out in so conspicuous a way as to make it difficult to believe that different notes of the chords are not struck by different human fingers. The matter opens up a wide field of discussion, and suggests considerable possibilities in the way of quantitative laboratory measurements. For the present, it may be sufficient to suggest that those of your readers who possess the new musical instruments of the twentieth century suitable for the purpose should, if they have not already done so, perform the experiment for themselves; they will soon be rewarded by being able to enjoy their music in a way they have never enjoyed it previously. G. H. BRYAN.

Cost of Scientific Education in Germany and England.

I NOTICE, in the issue of NATURE of December 4, that you quote Mr. Holzapfel's letter to the *Times* on the cost of scientific education in Germany and England. Although, unfortunately, there can be no dispute as to the great difference between the fees charged in Germany and in England, I think it right that the fees of King's College should be correctly stated. The sum quoted by Mr. Holzapfel represents the charge made for chemistry and *physics*; for chemistry only it was 34*l.* 18*s.* for the year. I have no knowledge of the amount of instruction which the other son obtained for 7*l.* at Aachen. WALTER SMITH, Secretary.

King's College, London, W.C., December 9.

THE REPRODUCTION OF COLOURS BY PHOTOGRAPHY.

THE services which photography has rendered to science are now well recognised, and its value for purposes both of observation and record is well known and admitted. It is probably not so well known that methods now exist by which not only the form, but the colour, of natural objects can be represented with approximate fidelity. We are fortunate in being able to illustrate this fact by a plate giving some excellent reproductions of birds' eggs, produced under the superintendence of Mr. H. E. Dresser, entirely by photographic methods, and without the intervention of an artist.

There is no need to dwell on the value of such work. For many scientific purposes it is as important to record colour as shape, and if this can be done in a trustworthy manner, a new and useful power is placed at the disposal of the teacher of science and of the writer of scientific books. The difficulty about the three-colour process of photography is that it is extremely difficult to make certain that the colours are reproduced with sufficient accuracy for scientific work. Accuracy enough for pictorial purposes is easily attained, but absolute truth to nature is quite another thing. The reasons for this are various. The photographic gradation of light intensities, in the case of both white light and of its various components, is generally different from the visual gradation, and even if accuracy is ensured in a narrow range of tones, it is hardly possible to make certain of its being secured in wider ranges. Another difficulty is that pigments have to be employed, and such pigments can never, of course, give pure colours. The consequence of this is that in the production of the picture it is necessary to vary the intensity of the different colouring agents employed until a satisfactory result is obtained. There is thus considerable room for judgment and dexterity, and the final result is not automatic, but depends on the artistic skill of the person who produces the picture. The whole process is, it must be admitted, of the character of a makeshift, but at the same time, when carefully employed it is a makeshift of considerable practical use.

Mr. Dresser, in the article printed below, deals only with the representation of natural objects for purposes of book illustration. An equally valuable application of the process is for the production of lantern slides for purposes of demonstration, and, as many of our readers are well aware, the process is beginning to be largely used for such purposes. A lantern slide coloured by hand is at best but a poor thing, and though a few very skilful operators—such as Mr. Cyril Davenport, of the British Museum—have by a combination of microscopic sight and great deftness of manipulation succeeded in producing some remarkable results, even these will hardly stand the large amount of magnification required by the lantern. Now a slide made by the three-colour process will stand as much enlarging as any ordinary photographic slide, and will give a reasonably close approximation to the natural colours of the subject. The process is applicable to any specimen which can be photographed. Excellent reproductions of microscopic objects have thus been produced; botanical specimens, birds, beetles and butterflies have all been rendered with great beauty and with really close accuracy to nature. Those who were present at Prof. Poulton's lectures at the Royal Institution last session had the opportunity of admiring the exquisitely coloured pictures he showed of insects, all produced by the process, which, first practically demonstrated by Mr. F. E. Ives, has since been further developed by Mr. Sanger Shepherd and others in this country.

Although, as said above, absolute accuracy is very difficult, or even impossible, to ensure—certainly not by automatic means—it is not too much to say that any photographer ought, after a very little practice, to be able to produce useful and serviceable illustrations for lecture purposes if he is content with something which, though not perhaps the best possible, is infinitely superior to anything which can be produced by painting an ordinary monochrome lantern slide.

Mr. Dresser in his remarks places, perhaps, needless stress on the difficulties of the process, and we are not quite disposed to agree with him as to its unsuitability for many purposes which he mentions. Although the exposures he gives may have been necessary by reason of the conditions under which his pictures were produced—namely, the photographing of the objects life size through a ruled screen and by the use of daylight at a time of the year when the light is not very good—it is a very different matter when it is required to produce illustrations for the lantern. In an ordinary studio, the exposure may take from, say, three minutes to a quarter of an hour through the red screen, which of course takes the longest time, while for out-of-door views in bright sunshine, with a moderate aperture of the lens, it is a matter of seconds only.

As a supplement to Mr. Dresser's account of the work he has carried on, we have added a summary of the account of the process given by Sir Henry Trueman Wood at the Royal Society's conversazione last May, when the rationale of the process was demonstrated.

THE THREE-COLOUR PHOTOGRAPHIC PROCESS.

To produce a photograph in colour direct from nature has for many years past been the dream and cherished aim of many photographers, but, so far as I can ascertain, these efforts have not met with success. By a happy combination, however, of the camera and the printing press, the so-called three-colour process has been so far perfected as to have become a commercial success, and, though still, perhaps, in its infancy, bids fair to become a serious rival to chromolithography, not only on account of its accuracy, but also because of its cheapness. Moreover, in the case of a larger number of copies being required, the total cost is considerably below that of chromolithography.

Upwards of twenty years ago, when the publication of my "Birds of Europe" was drawing to a close, I commenced to collect materials for a companion work on the eggs of European birds. When, however, it arrived at a question of illustrations, I found that I could not get plates sufficiently well and cheaply executed by any then known process. Besides which I could find no artist who could reproduce eggs in water-colour satisfactorily, and indeed, at the present time, I know of only one, a Danish artist, who can paint eggs with sufficient accuracy, and he is at present engaged on the illustrations for the British Museum "Catalogue of Eggs." Nor can he copy all sorts of eggs correctly, for in some species the markings are so minute and varied that no artist could exactly reproduce them.

In 1900, however, I saw a plate of fruit, photographed directly from the object, without the intervention of an artist, and reproduced by the three-colour process, which gave me the idea that it would be specially suited for the reproduction of natural history objects, and I at once commenced a series of experiments to test it with the assistance of Mr. I. D. Geddes, manager to Messrs. André and Sleigh, Ltd., of Bushey, Herts, and to his active cooperation I am indebted for the success that has crowned my endeavours. To produce the coloured picture three negatives are made from the objects on specially sensitised plates, which are exposed through "light filters" placed behind the lens. These filters separate out the colours of the objects into what are known as the primary colours—approximately red, blue and green. The negatives so obtained are then employed in the usual manner for the production of half-tone blocks—that is to say, each of the three pictures representing the separated red, blue and green images are etched as type blocks on copper for printing in the ordinary press, and it must be noted that the pictures as engraved on the copper blocks are made up of very fine dots. The plates are printed in the colour complementary to that of the filter through which each was taken, *i.e.* the red-filter picture in blue, the green in red and the blue in yellow. The printing of the plates is effected on three presses, one for each colour; the yellow image is first printed, then the red over the yellow printing, and, lastly, the blue over the red and yellow, and in each case the colour is allowed to dry before the next colour is printed. The registration of one colour over the other must be accurate, otherwise a blurring of the whole picture occurs. The colours used for printing are mixed each to a standard tint, which is only departed from in very exceptional cases.

The length of exposure for the process varies very much according to the conditions. As carried out for me by Messrs. André and Sleigh, in which the pictures were taken with a light-filter, a prism and a ruled screen interposed, the exposures were very long, the blue, approximately, ten to fifteen minutes, the green thirty to forty minutes, and the red nearly two hours. This process is eminently adapted for the copying of paintings, but the sole aim of the experiments made has been with a view to reproduce natural history objects, and more especially eggs, without the intervention of an artist.

Mammals cannot be photographed from living examples, as the exposure required is too long, and can only be done from paintings, for the reproductions are so very accurate that if photographed from stuffed specimens it is painfully apparent that they were stuffed. The same may be said with regard to birds, but when photographed from well-stuffed skins every character is most accurately reproduced, and such plates are consequently of extreme scientific value. Some fishes and crustaceans retain their colours for some time after death, whereas others fade almost immediately; the former of these can in most cases be reproduced from the specimens direct, but as regards the latter it will be necessary to employ an artist.

Shells of all kinds are specially adapted for this process, as colour-photography brings out even the bright iridescent colourings so characteristic of some species.

Flowers and plants, however, present serious difficulties, owing also to the long exposure required. Cut flowers will move and fade, and growing plants are sure also to move within three hours and thus spoil the pictures. Butterflies, moths and other insects can be photographed from the specimens direct if these are perfect, but they are often slightly damaged in catching, or in drying they become somewhat distorted, and any slight imperfection cannot be hidden, but is most faithfully reproduced; hence it is generally advisable to photograph from water-colour drawings of these objects.

Birds' eggs have chiefly occupied my attention, and with these I have been most successful, so much so that I purpose now to bring out my work on eggs, illustrated by this process from the eggs direct, without the intervention of an artist. At first I found a difficulty with the shadows, and tried the effect of a dark background; but as this took from the characteristic colours of some species, I had to revert to a pale background, and by degrees have overcome the difficulties, as will be seen from the plate accompanying the present article. The eggs figured on this plate are as follows:—

Figs. 1, 2, 3, eggs of the Lesser Kestrel, *Falco cenchris*; Figs. 4, 5, eggs of the Honey Buzzard, *Pernis apivorus*; Fig. 6, egg of the Levant Sparrowhawk, *Astur brevipes*; Fig. 7, egg of the Shikra Sparrowhawk, *Astur badius*; Figs. 8, 9, 10, eggs of the Blackwinged Kite, *Elanus coeruleus*. All these specimens have been selected to show the greatest variation in these eggs, and also to test the process.

H. E. DRESSER.

PRINCIPLES OF THREE-COLOUR PHOTOGRAPHY.[1]

The reproduction of the camera picture in its natural colours is still an unsolved problem, for Lippmann's results can hardly be said to have passed the experimental stage. They still lack practical application. All that can be done by photographic means is to select and combine colours, so as to produce an approximately correct reproduction of the colours of any natural object. The colour itself must be provided by the use of dyes, stains or pigments.

The principal application of the three-colour process

[1] Subject-matter of a demonstration given at the conversazione of the Royal Society on May 14 by Sir H. Trueman Wood.

is for the production of printed illustrations, but for purposes of demonstration its application to the production of pictures for exhibition by the lantern is much more convenient. By the use of a triple lantern the light from a single source can be divided up into three beams. If in the path of the beams we place screens of coloured glass of colours corresponding with the three primary colour sensations—red, green and blue—we have, of course, a disc of each colour projected on the lantern screen. If by moving the lantern lenses the three discs are caused to overlap, the colours will be mixed and combined. Where all three colours overlap there will be a white patch. Where only two overlap there will be a patch caused by the combination of those two colours, and this of necessity will be complementary to the third. We have therefore on the screen a coloured pattern showing white, the three primaries and their three complementary colours.

If in front of each lens of the lantern we introduce a simple pattern cut out of black paper, we shall, when the three images are separated on the lantern sheet, get three coloured reproductions of the three patterns. If they are of a suitable shape and suitably arranged we can combine these into a variegated pattern on the screen. We may take, for instance, such a simple pattern as a half-circle; then if we arrange the three half-circles in such a way that they do not coincide when projected together on the lantern sheet, but combine and overlap so as to form one complete circle, this circle will be divided into six sectors, three of which will show the primary colours and the other three their complementaries.

This simple experiment shows that it is possible to get a coloured picture by means of a black and white pattern and the three coloured glasses. In it, however, only the complementary colours are shown, because equal amounts of the primaries are combined. To get other tints, varying amounts of one or more of the component colours have to be used. Experimentally this is easily done by introducing in front of one of the lenses of the lantern an optical wedge—a sheet of glass coated with a neutral-tinted film, graduated from transparency at one end to opacity at the other. By cutting out, say, more or less of the red, we get a series of browns, greyish blues, &c.; by diminishing the green we get salmon colour, yellow ochre, &c. By this means it is evident that any desired tint which the human eye can appreciate can readily be produced.

Now a picture is only a complicated coloured pattern, and if we can analyse a picture and resolve its colours into the three components, arranged in their proper shapes, the combination of these three components will reproduce the picture as regards both shape and colour. Such analysis is possible by photography. A photograph taken through a red screen gives us the red component, and by using blue and green screens the blue and green components can be obtained. It is to be remembered that these photographs are merely monochrome photographs. They are simply ordinary photographs taken by a portion of the light of the spectrum, instead of by the whole of it. Making positive prints from negatives thus produced and projecting them on the screen, they show like ordinary lantern slides, except that each picture looks rather incomplete. In the red-light picture blue objects are but faintly reproduced. In the blue-light picture the red objects appear but feebly. When the coloured glass screens are interposed in front of the monochrome positives we get three pictures coloured red, green and blue respectively, and a combination of these on the sheet shows the original object in all its varied colours.[1]

[1] The ingenious photochromoscope of Mr. Ives works on precisely similar principles, except that the three coloured pictures are combined in the eye of the observer, instead of on the lantern screen.

The use of the triple lantern, however, is not very convenient, and there are certain drawbacks to its employment, though it suggests a possible means for the production of kinematograph pictures in colour. This is not yet possible, but it is conceivable that photographic films might be made capable of taking instantaneous pictures through the coloured screens, and that mechanism of sufficient accuracy could be constructed to register a series of three such pictures on a screen, so that they might be shown in the way animated photographs are now shown.

For practical purposes it is more convenient if we can have our coloured pictures in the form of an ordinary slide, which can be shown in the ordinary single lantern. Now it is quite obvious that with a single lantern we cannot use three coloured screens, one in front of the other. In the triple lantern we are mixing coloured lights, adding colour to colour. The superposition of one screen upon another in a single lantern merely means that only those rays will pass which can get through both screens, and the three screens together in the lantern would, of course, obstruct all the light, and the result would be nothing but darkness. With the triple lantern we are using a method of addition; with a single lantern we must use a method of subtraction or absorption.

The end can, however, be attained by the use of a film of bichromated gelatin, coated on a celluloid support. The film is printed and washed in the usual manner of carbon printing. The resulting relief in colourless gelatin is then stained the complementary colour to that by which the negative was taken. The need for employing the complementary colour is not difficult to understand. The bright parts of the red-screen positive represent bright red light. The dark parts represent the absence of red light, red shadows. When the film is stained, the transparent parts take little or no stain, the denser and thicker parts take the stain in proportion to their thickness. They should therefore be stained the opposite to red, the complementary to red (it is convenient to think of it as "minus red"), or blue-green. So the green-screen print must be stained "minus green," or pink, and the blue-screen print must be stained "minus blue," or yellow.

If we now take the three films and put the blue film in the lantern, we get a blue picture on the sheet. Putting in front of this the yellow film, our picture becomes partly blue, partly yellow and partly green, and we have some accession of detail. Adding again to this the pink film, we get at once all the different colours of the original object, and the picture is recognised as a practically correct reproduction of the original.

If the three films, instead of being mounted in such a way that they can be shown in the lantern, are stripped from their supports and superposed one above the other on a sheet of white paper, we get a coloured picture suitable for use as a book illustration. This process is quite practical, but it is by no means easy, and, of course, it is useless for the production of large numbers. For commercial purposes no process can be of much service which is not applicable to the printing-press. Now it must be familiar to most people that a printing-block can be produced from any photographic negative. The methods by which this is effected are well known, and they are in constant use, the great bulk of the black and white illustrations in magazines and newspapers being now produced by them. It is, therefore, not difficult to see that if from each of our negatives we make a printing-block and use the three blocks to print—the blue-screen block in yellow ink, the green-screen block in red ink and the red-screen block in blue ink—we are merely varying the process by substituting films of printing-ink for films of stained gelatin. This is, indeed, in barest outline the method by which the very numerous coloured illustrations made by the three-colour process are all produced.

FIRE-WALKING IN FIJI.[1]

IN connection with the Coronation festivities at Suva, there was to have been a fire-walking ceremony, but, owing to the illness of the King, the Government of Fiji decided that nothing could take place; however, a large party of excursionists from New Zealand managed unofficially to obtain an exhibition of the fire-walking. The following notes have been abstracted mainly from an account by Mr. Walter Burke, in the Christchurch *Weekly Press* (July 16, 1902) and from a condensed report in the *Evening Star* of a paper read before the Otago Institute by Dr. Robert Fulton, which some time next year will be published in the *Transactions*.

FIG. 1. The Natives walking on the heated stones. (From the Auckland *Weekly News*.)

The ceremony was performed on the island of M'Benga, near Suva, by members of the Nga Ngalita tribe, all of whom are credited with being specially gifted in the way of heat-resistance. In the centre of a space cleared in a coconut grove was a circular pit, about 20 feet in diameter and 2 feet in depth, the earth from the centre being piled round the periphery. Poles were placed radiating from the centre, dry palm fronds were placed on these and firewood stacked above. Finally, large stones were heaped on the top until the whole pile was several feet in height. The fire was lit about forty-eight hours before the ceremony took place, and it was kept fed with fresh supplies of wood. Eventually the whole mass glowed with a white heat; it was not comfortable to stand within a few feet of it, and also it was dangerous, as large splinters of stone flew far and wide.

As the hour for the exhibition approached, the natives brought green saplings about 20 feet in length, armfuls of green branches, and masses of green vines of great length and considerable thickness. The following is from Mr. Burke's account:—

"The fire is now sinking, and occasionally a large stone drops through. There is little smoke and the stones fairly glow. Now the workers close in. The smaller vines are fastened in loops at the ends of the long saplings. A loop is dropped over the end of a log not yet burnt out, and with loud chants the log is drawn out. This is repeated till no logs are left. The ends of the saplings continually burst into flames as they touch the stones. At last there seems to be nothing left in the pit but stones, some of which are shivered to pieces by the great heat. The large hawser-like vine now comes into use. This is thrown across the pit to one side, and with the saplings the men force it down into the glowing stones. Now dozens of willing hands pull at the ends, and the stones are turned over and over and flattened out. Many stones that were at the bottom are now on top, and *vice versâ*. This is done until the stones present a fairly even surface, but critical men, still unsatisfied, probe amongst the stones with the saplings and turn the smoothed side uppermost. While they are doing this, the green saplings blaze vigorously.

FIG. 2.—On the burning leaves. Immediately after the fire-walking, green leaves were thrown on the hot stones. The fire-walkers then leaped back on to the leaves, which burned and gave off great masses of smoke. In this illustration, the men can be seen dimly through the smoke. (From the Christchurch *Weekly Press*.)

"Now all is ready for the grand finale. The workers step back. One of the men who is to walk comes out for the examination by Drs. Smith and Fulton, of

[1] The interesting illustrations which accompany this article have been reproduced from the Auckland *Weekly News* and the Christchurch *Weekly Press*, in which several other pictures of a similar remarkable character are given. As several months would elapse before permission to use these illustrations could be obtained from New Zealand, we have taken the liberty to reproduce two from the periodicals mentioned. It would be a pity to delay bringing pictures of such scientific interest before readers of NATURE.—[ED.]

Dunedin, who are unable to discover anything out of the ordinary. The chief asks for silence and a hush falls on the scene. The assembled natives break into loud cries, and along a track in the jungle-like growth can be seen a party of ten Fijians fantastically dressed.

"Without hesitation or haste, they step on to the stones and walk round the pit, taking some ten to fifteen seconds to complete the circuit. They step off quickly, and in a moment great masses of green leaves are thrown on to the centre. The fire-walkers rush back and press down the leaves with their feet and hands. The steam rising from the leaves envelops them in a cloud. Baskets of native food are passed in, and more green leaves are heaped over until a mound is made."

Dr. Fulton states that the man Dr. Smith and he examined before the fire-walking was of fine physique, with a pulse a little over 90 and the hands and feet cooler than the rest of the body. The feet were perfectly clean and odourless, and no preparation could be detected on them. The soles were yellowish-white, perfectly smooth and pliable, and like soft kid. The man wore a *sulu* (petticoat) of dry hibiscus bark and canna leaves, with small anklets of dry bracken. Each man as he walked kept his eyes on the stones. One man was examined afterwards; his pulse was about 120; the soles of the feet seemed cool, if not cold, but on running the hand up the leg, a most pronounced difference in temperature was observable; on the calf, it was like that of a man in a high fever. None of his vegetable clothing was scorched, not even the dry bracken anklets, and the short, black, crisp hairs on the legs were not singed. Dr. Fulton went to the edge of the pit immediately after the ceremony and stirred up some of the stones with his foot. He stood for a second on one or two and found that they did not brown his boots, though evidently they were too hot to handle. He asked a native to get him one of the stones, and the man coolly walked up and began to move about the heated stones with his bare feet. This was not one of the "fire-walking" men, but one of those who had come from Suva. He raked out a piece of stone from the heap, but it was too hot to hold in the hand.

The explanation Dr. Fulton offers is as follows. The arrangements for heating were peculiar; if what was required was merely a surface of red-hot stones to walk upon, it would be easier to lay flat stones in the pit and to maintain a huge fire on them. The stones took forty-eight hours to get to their "proper" condition, and the subsequent cooking of the food took two days instead of an hour or so. The stones also were found to cool very slowly. The same stones are never used twice. They are gradually heated until split by the expansion of the contained water, and are then carefully arranged fractured side upwards. The stone that was examined was an augite-andesite of ordinary type. Prof. Park, of the Otago School of Mines, found that, taking the thermal conductivity of copper as equal to 1000, that of andesite is 6·67, that is, it is a very feeble conductor of heat. In testing the radiation, iron being the standard at 100, andesite is 48. Thus the fractured, or inside, surface of the stone, owing to its slow conductivity, does not receive nearly the amount of heat one would expect, and, owing to the slow radiation of heat, the foot is not burnt when coming into contact with the stone for a second or less; as a matter of fact, the sole of the foot was at no time in contact with a hot stone for more than half a second. The foot is naturally cold or artificially cooled; it is a well-known fact that one can bear with cold feet for a long time (up to a minute in some instances) heat from a fire which would be insupportable for five seconds at ordinary foot temperature.

A good deal has been written at various times on walking on heated stones or glowing embers. It will be in the knowledge of our readers that there was published in NATURE of August 22, 1901, an article on Tahitian fire-walking, by Prof. S. P. Langley, in which a somewhat similar explanation was given. It is satisfactory to find that these investigations by scientific men agree, on the whole, with one another in principle, and that a rational explanation is forthcoming for a sensational performance which unskilled white observers usually regard as mysterious or even as miraculous. The walking on glowing embers, which is well known in parts of India, as recently described in the *Bulletin* of the Madras Government Museum (vol. iv. 1901, p. 55), probably has another solution. The fire-walking ceremonies in India, Japan and elsewhere require to be carefully studied by trained observers. A. C. H.

THE PRESENT STATE OF WIRELESS TELEGRAPHY.

IT is now eighteen months since we last attempted in these columns to take a general survey of the development of wireless telegraphy. In the history of a science which has enlisted the services of so many skilled experimentalists, each of whom has made rapid progress along his own lines, eighteen months is a comparatively long period; as a result, we are compelled to-day to regard the subject from a very different point of view. At that time, there were practically only two systems—Mr. Marconi's and Prof. Slaby's—which had advanced to such a degree of perfection that they deserved special consideration. To-day, it would hardly be too much to say that in every civilised nation there are one or more inventors with a carefully worked-out and tested system ready for general use. Particulars of these different systems have been published from time to time and have been duly referred to in NATURE; unfortunately, the information published is not, as a rule, of the kind that one most desires to obtain; too often it is obviously "inspired," and consists for the most part of insufficiently supported claims to successful syntonisation, or to record making in the way of long-distance transmission or rapid signalling, information which is very acceptable to the daily papers, which forget one day what they have published the day before, but of little use to those who are seriously interested in the subject.

So far as can be judged, the various systems differ chiefly in matters of detail, the design of circuits and the special construction and arrangement of apparatus; improvements depending on the introduction of a principle fundamentally new are few and far between. We do not wish to underrate the value of these detailed improvements; they are, as we well know, often the talismans converting failure into success, but their interest is mainly for the specialist It is not our intention, therefore, to enter into a detailed examination of the different systems; to do so would only involve us in a mass of technicalities from which the reader would probably "come out by that same door where in he went." Those who wish for this information must be referred to the technical Press or to the files in the Patent Office, where they will probably find, as, for example, in the two hundred odd claims in Mr. Fessenden's patents, all the particulars they desire. We propose rather to treat the subject on a broader basis, and to endeavour to form an estimate of how far wireless telegraphy in its present state has fulfilled the expectations that have been raised in the past or justifies hopes that may now be entertained for a future of wide utility.

The first question that one feels inclined to ask is, At what end are all these inventors aiming? Is it to devise a system of wireless telegraphy to compete with the ordinary telegraphic methods, or is it for what seems to us the more useful purpose of creating a means of communication where none now exists, especially between ship and ship and ship and shore? It would seem that in some instances, as,

for example, that of the Marconi Company, the former purpose is almost as much in view as the latter. In the former case, there can be no question but that absolute syntonisation is necessary; in the latter, it is less important and even in some respects undesirable, but, on the other hand, it is essential that the different systems should work together so that any ship should be able to signal to any station. It would be a great misfortune if this principle is lost sight of in the rivalry between competing methods and if we thereby lose what seems to be in reality the greatest benefit wireless telegraphy can confer, the increase of the safety and convenience of travelling by sea. This is, we think, the most urgent problem that wireless telegraphy presents to-day, and we trust that it will find a really satisfactory solution at the coming Berlin Conference.

The attempts which have been made at syntonisation are, indeed, far from encouraging. It is true that almost every inventor claims that he has solved the problem, but all the experiments that have been quoted are open to criticism. It is important to recognise what a successful solution really means; it is not sufficient to demonstrate, as has been done many times, that two messages can be transmitted or received at the same time by the same installation without interference: that, in short, duplexing is possible: this is a great step, no doubt, but to solve the problem it is necessary that the tuned transmitter shall affect no other receivers than those syntonised with it, and that the tuned receiver shall respond only to the proper waves; this, it will be seen, is a requirement much harder to satisfy. As an example, showing how far existing practice is from satisfying these conditions, we may quote the case of the recent long-distance work done by the Marconi Company. Mr. Marconi, it will be remembered, has several times claimed to have solved the problem of syntonisation, and, confident of having done so, issued a challenge last February to Sir W. Preece or Sir O. Lodge to intercept any of his messages, offering to put a station, in the neighbourhood of his Poldhu station, at their service. This challenge has been answered in a conclusive manner during the past month by Mr. Nevil Maskelyne, who showed that the installation which he was working at Portcurnow had been receiving the messages sent to the *Carlo Alberto* on her recent cruise from England to Italy (see the *Electrician*, vol. l., pp. 22 and 105). It is clear, therefore, that, with no special preparation on either side, it is possible to tap the signals that are being sent by the Marconi Company over long distances, and in face of this the claims to a real solution of the syntonisation problem fall to the ground. We doubt whether any other system would stand the same test.

But if on this side the outlook is somewhat dispiriting, in other directions matters are more encouraging. This year has witnessed the remarkable achievements by the Marconi Company in long-distance work. It has been shown that it is possible to signal across the Atlantic, a distance of more than 2000 miles over water; and in the cruise of the *Carlo Alberto* signals were transmitted a distance of 750 miles over land and water. To cover these great distances, the power used at the transmitting station has to be correspondingly great; in consequence, the signalling was only from Poldhu to the ship and not in the reverse direction. The importance of these experiments, however, lies rather in the conclusive demonstration of the fact that it is only a question of providing sufficient power to signal over any distance, however great, and therefore no fears need be entertained of the utility of the wireless telegraph being limited by considerations of distance. No other experimenter has attained such success in long-distance work as Mr. Marconi, but no other experimenter has used such large power for transmission. Unfortunately, sufficient particulars are not available to enable a comparison to be made between the distances attained with different systems using the same amount of power; this is a point on which the publication of trustworthy data would be of the highest value. An interesting phenomenon brought out by Mr. Marconi's long-distance work is the effect produced by daylight on transmission. It is found that the signals carry much further during the night (*i.e.* night at the transmitting station), the result being due, it is suggested to the discharging effect of sunlight on the aërial wire (see NATURE, vol. lxvi. p. 385).

With reference to long-distance work, the interesting experiments of M. Guarini with an automatic repeater may be quoted. This inventor designed an apparatus which should pick up a message received from one station, A, and pass it on to a second station, B, which was out of the range of the signals transmitted direct from A. The principle of this apparatus will be understood from the accompanying diagram (Fig. 1), in which, for the sake of clearness, only the essential circuits are shown. The aërial wire A at the repeating station is connected through the contact 1 of the relay R_1 and through the primary of a transformer T to earth; it is also connected through the spark gap S to earth. The coherer is connected in series with the secondary of T and a condenser. When a signal is received, the resistance of the coherer is broken down, and the battery B_1 sends a current through it and the relay R_2, thus closing at the contact 3 the

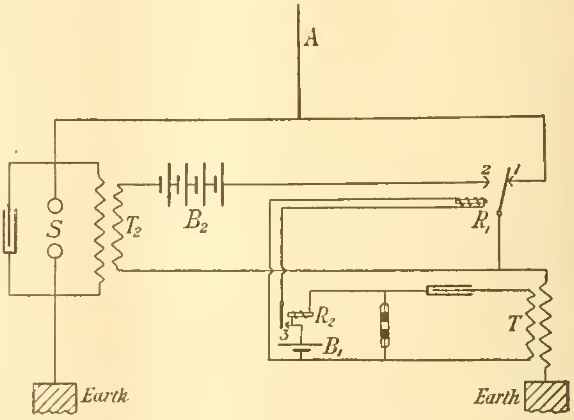

FIG. 1.—Diagram of Circuits in Guarini's Repeater.

circuit of the relay R_1. The contact arm of R_1 swings over to 2, thus disconnecting the aërial from the receiving circuit and closing the primary of the induction coil T_2, thereby causing a spark to pass across the gap, which means that the signal is sent out again from the aërial A. The coherer being tapped back, the various circuits are opened, and the arm of R_1 returns to its original position and so is ready to receive the next signal. Experiments were carried out between Antwerp and Brussels (42 km.), the repeating station being at Malines, about half-way between the two; the results were promising, though the repeater did not prove absolutely trustworthy.

We may now turn from the consideration of the results achieved to the apparatus that has been used. In the transmitting apparatus, attention has been chiefly devoted to devising means of generating oscillations of definite wave-length. None of these call for special comment. In some cases, for obtaining the spark, alternating-current generators have been employed in connection with step-up transformers instead of induction coils. This is the case in the de Forest system, which, it may be remarked, claims the record for speed of forty-eight words per minute; the alternator generates, at 500 volts, 60 cycles, and this is stepped up to 25,000 volts for sparking; the signals are formed by interrupting the primary circuit of the transformer by means of a specially designed key. The difficulty of breaking a large current in this way is consider-

able, and has obviously proved a stumbling-block to the Marconi Company, as it forms the subject-matter of two or three patents taken out by Prof. Fleming and the Company. Some of the methods described therein are exceedingly ingenious, but, unfortunately, space does not allow us to describe them here, especially as their bearing on wireless telegraphy is only indirect.

With the exception of the magnetic detector devised by Mr. Marconi and tested during the cruise of the *Carlo Alberto*, practically all the different systems make use of the coherer principle for receiving. The actual type of coherer used differs considerably in the several cases. For long-distance work, it has generally been found most suitable to use a coherer which requires no tapping back, but spontaneously returns to its normal condition, this being connected in parallel with a telephone. One of the chief advantages of this arrangement lies in the fact that the energy required to give audible signals in the telephone is much less than that needed to work a relay. There are several different coherers working on this principle—the principle really of the microphone; in the system devised by M. Popoff, carbon granules form the loose contacts, the resistance, which is normally high, being broken down by the received waves and the coherer then restoring itself to its original condition; the change

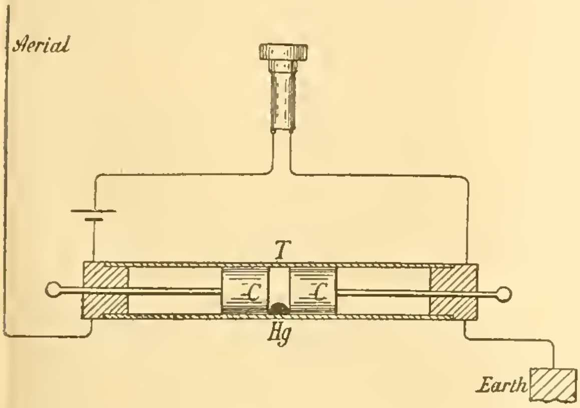

Fig. 2.—Castelli Coherer and Connections.

in the current through the coherer causes a click in the telephone. In the de Forest system, an electrolytic "anticoherer" is used; this has a paste, composed of a viscous material, loose conducting particles and an electrolyte, between suitable electrodes. In the normal condition, the conducting particles bridge the gap and give the receiver a low resistance; electrolysis is set up by the received oscillations and the consequent polarisation greatly increases the resistance. Of the coherers of this type, the greatest interest attaches to the Castelli coherer. This, invented by a semaphorist in the Italian navy, was used by Mr. Marconi in his first Transatlantic experiments. Its construction is shown in Fig. 2. Two iron or carbon electrodes, C C, fit into the tube T and are connected by a single drop of mercury Hg. The connections shown are, of course, the same in the case of the two other coherers just described. When electrical oscillations reach the tube, the mercury coheres to the electrodes, but returns at once to its normal condition when the stimulus ceases. The magnetic detector to which we have made reference above was described by Mr. Marconi in a paper read before the Royal Society last June. Fig. 3 shows the principle of its construction. It consists of a core of thin iron wires, I, over which are wound two coils of fine copper wire, C_1 and C_2. The outer core, C_1, is connected to a telephone receiver and the inner, C_2 to the aërial and earth or to the secondary of a transformer the primary of which is connected to the aërial and earth. The iron core is magnetised by a permanent magnet, M, at one end, which is rotated by clockwork so as to produce a continual slow change in the magnetisation, which, however, owing to the hysteresis, lags behind the magnetising force. When oscillatory currents pass through the inner coil, there is a sudden decrease in the hysteresis, due apparently to the molecules being released from restraint: a corresponding sudden variation in the magnetisation of the iron results, and this induces a current in the outer winding connected to the telephone.

Such, in brief, are the more important advances that have been made in the practice of wireless telegraphy during the past year. In addition, much work has been done on the purely scientific side of the subject, the action of the coherer in particular having been submitted to somewhat rigorous examination, work which has already produced results which may prove both of great physical and great practical value. It may fairly be said that we know now, with a considerable degree of certainty, some of the more useful services which wireless telegraphy may be relied upon to perform. Already its commercial application is considerable; many ships, in the navies of this and other countries and in the merchant services, are equipped with wireless telegraphic apparatus which has, we believe, fully justified its instal-

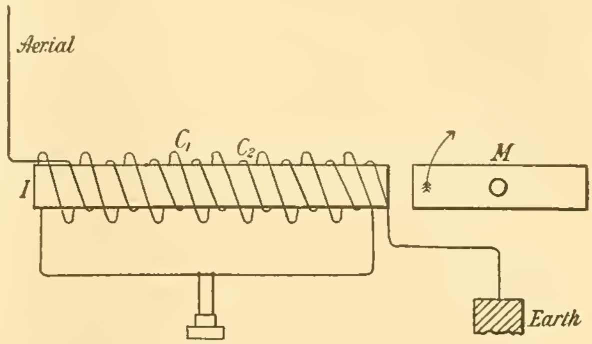

Fig. 3.—Diagram of Marconi's Detector.

lation. It is in this direction that we look with the most confidence for a steady increase in its application, and we would rather hear of a few more ships being thus equipped than of another "S" being transmitted across the Atlantic.

Maurice Solomon.

NOTES.

The Paris correspondent of the *Times* announces the death of M. Dehérain, professor of vegetable physiology in the Museum of Natural History, and of M. Hautefeuille, mineralogist at the Faculty of Sciences. Both were members of the Paris Academy of Sciences. The death is also announced of M. Alexandre Bertrand, one of the original founders of the fine museum of St. Germain, of which he had been curator since 1862. He was also professor at the École de Louvre of national archæology, and his fame as an archæologist was world-wide.

The great dam on the Nile at Assuan is to be inaugurated by the Duke and Duchess of Connaught as we go to press with this number. Sir Benjamin Baker, K.C.M.G., has been appointed to be a Knight Commander of the Order of the Bath, in recognition of his services in connection with the construction of the Nile reservoir. Other honours conferred in connection with the work are:—To be G.C.M.G., Sir William Edmund Garstin, K.C.M.G., Under-Secretary of State for Public Works in Egypt. To be K.C.M.G., Major R. H. Brown, R.E., C.M.G.,

and Mr. W. Willcocks, C.M.G., of the Egyptian Irrigation Department. To be C.M.G., Mr. A. L. Webb, Mr. K. E. Verschoyle, Mr. M. Fitzmaurice and Mr. G. H. Stephens.

THE suggestion that the British Association should meet in South Africa in 1905 was mentioned in these columns some time ago. The following statement with reference to the meeting has now been published in the daily papers:—Reuter's Agency is informed that the suggestion that the British Association should hold its annual meeting for 1895 in South Africa emanated from the new South African Association of Science, of which Sir D. Gill, Astronomer Royal for the Cape, is president. Before the last meeting of the British Association at Belfast, invitations were sent from the municipalities of Cape Town, Kimberley, Bulawayo and other centres in South Africa, and it is understood that these have been accepted, and that the session of 1905 will be held in South Africa. Scientific papers will be read at various centres in the South African Colonies, and visits will be paid to various places of interest. A sum of 7000*l.* has been collected in South Africa for the entertainment of the Association. While in Rhodesia, the men of science will be the guests of the Chartered Company, who will place the railways at their disposal and, among other things, take them by special train to the Zambesi, where they will stay at the new hotel to be erected near Victoria Falls. Probably the guests will leave England in a special steamer.

AT the meeting of the Royal Geographical Society on Monday, Dr. Sven Hedin described to a large audience the results of his explorations in Central Asia during the three years 1899–1902. Before the reading of the paper, it was announced that Dr. Sven Hedin had been awarded the Victorian medal of the Society for geographical survey. The scientific records and other material obtained during the expedition are of great value, and include some interesting evidence of secular movements in the region of Lop-nor. The surface of the lake of Kara-koshun was found to be about seven-and-a-half feet below the northern shore of the ancient lake of Lop-nor. The lake of Kara-koshun is gradually disappearing in the place where Prjevalsky found it, and slowly creeping northwards towards its ancient bed, where Dr. Hedin believes it will be found at no great distance of time. The lake is getting choked with mud and drift-sand and decaying vegetable matter; while, on the other hand, the northern part of the desiccated desert is being eroded and furrowed by the winds, and is thus growing deeper and deeper every year. As the lake moves, so do the vegetation and the various animals of the desert. They, as well as the fisher-folk, with their reed huts, follow after to the new shores, while the old lake gradually dries up. There are reasons for believing that in the far-off future the same phenomena will recur again, but in the reverse order, though the natural laws which will effect the reversal will remain precisely the same. Whenever that occurs it will be possible to determine the length of time required for these periodic changes. Dr. Hedin pointed out, however, that it is already known that in the year 265 A.D. the lake of Lop-nor lay in the northern part of the desert. Lop-nor is, as it were, the oscillating pendulum of the Tarim River, and each oscillation probably extends over a space of a thousand years or more.

THE following men of science have been elected honorary members of the Cambridge Philosophical Society:—Profs. Bayley Balfour, A. H. Becquerel, E. Fischer, Richard Heymons, J. H. van 't Hoff, M. Jordan, H. F. Osborn, W. K. von Röntgen, Corrado Segre and Hugo de Vries.

THE Antarctic relief ship *Morning*, carrying provisions for the *Discovery*, now in Antarctic regions, sailed from Wellington, New Zealand, on December 6.

THE *Times* correspondent at St. Thomas, in a message dated December 6, reports that Mont Pelée has been dangerously active during the past week. There has been a heavy fall of ashes, and vessels were advised not to approach the coast.

AN ascent of the Soufrière while still in a state of activity was made, on October 28, by Mr. J. P. Quinton, of the Botanic Station of Sierra Leone. Mr. Quinton and his party were the first to try the ascent since the eruption of October 15–16. Some of the ridges they had to cross were not more than six inches wide, with a fall of a thousand feet on either hand. The ascent took two and a half hours stiff climbing. Mr. Quinton found that the new crater had unwarrantably been held responsible for the mischief of October 15; only the old crater was doing anything. This was discharging volumes of steam and water, and was throwing stones and ashes to a height of 30ft. or more. But no lava at all seems to have been ejected. The steam comes up through a fissure in the south wall of the crater, hangs along in a depression close in under the south-eastern wall, and, finally gaining the summit, is blown over to the west, making it look as though it were coming from the new pit. The old crater is very much wider than it used to be and more funnel-like. Red-hot stones and ashes are piled up on all sides—in some places over the rims. All through the night and the following morning while the party was on the mountain, rumbling sounds were constantly emitted, with clouds of steam and showers of ashes.

A *Times* correspondent describes the recent eruptions in Guatemala as communicated to him by a resident in the republic. On October 24, at about 5 p.m., a violent eruption took place in the ravine which divides the volcano of Santa Maria from that of the Siete Orejas. At 5 a.m. on October 25, subdued noises were heard, emanating apparently from the direction of Quezaltenango. Later on the detonations grew louder. At 6 p.m. the eruption reached its climax. For about an hour the detonations had ceased, when, by a terrific outburst, the whole of the capital was thrown into a panic and everybody rushed out into the streets. This cannonade lasted for ten minutes, during which time the strongest built houses shook violently. At intervals the detonations continued through the night and in a less degree afterwards. The explosions were heard in the south of Nicaragua, and a telegram was received from San Salvador stating that the inhabitants had rushed into the streets in terror on hearing the noise. Quezaltenango was thirty-six hours in total darkness, during which time a heavy rain of ashes and sand had been falling. The manager of the Sabinas Estate, which lies just above the scene of the eruption, says that at about 5 o'clock on October 24 they were alarmed by a series of earthquakes of a throbbing nature, which appeared to come from below them. Almost simultaneously, a cloud of steam was seen to issue from the ravine already mentioned, about a league away. Soon ashes and sand, accompanied by small stones, commenced falling, and two hours later the odour of sulphur and gases was so great that he could hold out no longer, and he left on foot for Retalhuleu, a distance of some thirty miles. Reports from the other planters confirm the fear that the whole of the Costa Cuca, probably the richest coffee zone in the country, is totally ruined.

AMONG the lectures to be delivered at the Royal Institution before Easter, we notice the following:—Prof. H. S. Hele-Shaw, six lectures (adapted to young people) on locomotion, on the earth; through the water; in the air (experimentally illustrated); Prof. Allan Macfadyen, six lectures on the physiology of digestion; Sir William Abney, three lectures on recent advances in photographic science; Sir Robert Ball, three lectures on great problems in astronomy; Mr. A. J. Evans, three lectures on pre-Phœnician writing in Crete and its bearings on

the history of the alphabet; Sir Clements Markham, three lectures on Arctic and Antarctic exploration; Mr. G. R. M. Murray, three lectures on the flora of the open ocean; and six lectures by Lord Rayleigh. The Friday evening meetings will begin on January 16, when a discourse will be delivered by Prof. Dewar on low temperature investigations; succeeding discourses will probably be given by Dr. Tempest Anderson, Prof. W. E. Dalby, Prof. S. Delépine, Principal E. H. Griffiths, Dr. A. Liebmann, Prof. J. G. McKendrick, Prof. Karl Pearson, Prof. E. A. Schäfer, Prof. W. A. Herdman and Lord Rayleigh.

AFTER the formal acceptance, by the British Government, of the invitation to take part in the Universal Exhibition which is to be opened at St. Louis on May 1, 1904, it was decided to prepare and distribute an illustrated descriptive pamphlet for the guidance of intending exhibitors and visitors from the United Kingdom. The booklet sets forth the plan of the Exposition, gives estimates of the men and the historic events to be commemorated, provides a comprehensive review of the various exhibits, and explains the relations which foreign countries, the Government of the United States and the States of the Union bear to it. About twenty-five foreign countries, including Great Britain, France, Germany and Italy, have decided to take part in the Exhibition. France has already made a preliminary appropriation of 650,000 francs, and it is believed this will be at least doubled next year. Germany's exhibit is expected to be even finer than that at the last Paris Exhibition. Japan has made an initial grant of 800,000 yen (about 80,000*l*.). The British Government is to be asked, a *Times* correspondent says, to enlarge the scope of its acceptance, which is limited thus far to the assurance that complete exhibits will be made in art and education, and facilities afforded to industries.

ON Monday, at the Society of Arts, Sir George Birdwood, K.C.I.E., was given evidence of the regard in which he is held by many leaders of thought, for he was presented with a testimonial in the form of some handsome silver plate and a purse of money. In making the presentation on behalf of the committee and subscribers, Sir Owen Tudor Burne alluded to the fact of Sir George Birdwood's having entered the East India Company's service forty-eight years ago. Being afterwards stationed at Bombay, he became one of its leading citizens, founding, among other beneficial works, the Victoria and Albert Museum and the Victoria Gardens, besides greatly enlarging the local branch of the Royal Asiatic Society and throwing open its membership to public-spirited and learned Hindus, Mohammedans and Parsees; he was mainly instrumental in raising the necessary funds for the building and endowment of the Bombay University, and was also the author of various writings on Indian art and botany and Indian local and Imperial questions.

THE bending of two alabaster slabs in the Alhambra palace at Grenada was mentioned by Mr. Spencer Pickering (p. 81) in connection with a letter by Dr. See (p. 56) on the bending of a marble slab under its own weight. Dr. Bleekrode, writing from The Hague with reference to the Alhambra slabs, remarks that they are nearly 3 metres long, and are 23 centimetres wide and 5 centimetres thick. The curvature begins at a distance of about 1 metre above the floor and the radius is nearly 9 metres. The pressure is estimated to be equal to about 1600 kilogrammes. Dr. Bleekrode points out that the Alhambra was built at the end of the thirteenth century and began to deteriorate nearly two hundred years ago. He suggests that possibly if the masonry causing the pressure were removed, the slabs would become flat again, in which case the bending would have to be regarded merely as an effect of elasticity.

DR. T. A. JAGGAR, JUNR., of Harvard University, in a letter to *Science*, directs attention to a peculiar sequence followed by the great eruptions of Mont Pelée this year. Since May 5, eruptions of the first magnitude have occurred at intervals of increasing length, as will be noticed from the following dates of violent disturbances of the volcano;—May 5–May 8, three days; May 8–May 20, twelve days; May 20–June 6, seventeen days; June 6–July 9, thirty-three days; July 9–August 30, fifty-two days. The progressive increase of the interval between the eruptions does not follow any simple arithmetical law, but from a graphic representation of the facts a curve is obtained which suggests that the interval after August 30 has a length of 112 days. If that is the case, a great eruption of Mont Pelée might be expected to occur about December 20.

DURING the past week, this country has experienced abnormally cold weather, and sharp frosts have occurred at night, while the day temperatures have on several occasions only risen slightly above the freezing point. North-easterly and easterly winds have for the most part prevailed, and at times they have blown with considerable strength; snow has fallen in many places, and in the south of England the ground remained covered for some days. The cold spell has been caused by the extension of the European area of high barometric pressure over our Islands, and this has brought this country under the influence of the severe weather which has prevailed on the continent. On the night of December 6–7, the thermometer at Greenwich fell to 24°·5 in the screen and to 18°·7 on the grass, but still lower temperatures have been recorded in parts of England and Scotland. The anticyclone over northern Europe has apparently become fairly well established, and with its continuance the weather is likely to remain cold.

WE have received from Dr. Hergesell, president of the International Aëronautical Committee, a preliminary report upon the scientific balloon ascents made on the first Thursday in each of the months July, August and September last. The ascents, which were made by manned and unmanned balloons and kites, were joined in by Austria, France, Germany, Hungary and Russia on the continent, by England (Mr. Alexander), Scotland (Mr. Dines), and Blue Hill Observatory, in the United States. Readings at altitudes near or exceeding 10,000 metres were obtained in the following cases:—Berlin (July), −52°·5 C. at 15,690m., ground temperature 9°·4. Strassburg (August), −41°·7 at 10,160 m., temperature at starting 18°·4, and about half an hour later (5h. a.m.), −53°·1 at 11,900m., ground 16°·2. Berlin, −68° at 18,500m., ground 13°·5. Bath, −47°·2 at 9305m., temperature at starting (8h. a.m.) 15°·6; the greatest height reached was 11,350m. Strassburg (September), −54°·7 at 12,200m., ground 17°·7. Pavlovsk, −49°·7 at 11,100m., temperature at starting 13°. The ascents were made under the following barometric conditions:—In July, high pressure existed over the western part of Europe; in August and September, areas of low barometric pressure were prevalent.

WE have received from Dr. Robert Bell, acting director of the Geological Survey of Canada, the western sheet of the geological map of the Dominion, on a scale of fifty miles to an inch. It is very clearly printed in colours, and will be of much service as an index map to the structure of the country.

IN an article on the composite gneisses in Boylagh, West Donegal (*Proceedings* Royal Irish Academy, vol. xxiv., 1902), Prof. G. A. J. Cole argues that we have the intermingling and incorporation of two dissimilar masses of stratified and igneous material, and that the gneisses have resulted from the complex metamorphism to which the masses have been subjected.

MR. R. T. HILL (*Journal* of the Franklin Institute, August-October) gives a graphic account of the Beaumont oil-field, a district within the area of the coast prairie of the Texas, Louisiana and Mexican region. The oil was discovered in 1901 by a drill-hole through 1100 feet of clay and quicksand. A year later there were 136 wells, now there are 214, and more are being drilled. During the first year, 5½ million gallons of oil were obtained, and five or six times this amount is estimated as the product for 1902. The prairie land extends for nearly 400 miles along the Gulf of Mexico and from ten to fifty miles inland. The strata at a depth probably comprise bituminous Eocene clays, and they are overlaid by later Tertiary and Pleistocene sands and clays, nearly 3000 feet in thickness, which contain the oil; and these, again, are covered by prairie deposits of sea-mud and sand. A drill-hole has been carried to a depth of 3050 feet without touching the Eocene. In some localities, hot water has been struck below the oil, and the oil itself is sometimes hot. Gas has been encountered in some of the bore-holes. It is remarked that the water becomes not only hotter but more saline with increasing depth, thereby raising its capacity for the collection and flotation of oil, which is preserved in the porous strata overlying the Eocene clays and is sealed up by the superincumbent muddy sediments.

PROF. O. COMES, of Portici, Naples, has prepared a series of chronological charts which furnish data concerning the introduction, cultivation and general spread of tobacco for all important countries throughout the world.

WITH the present contribution (No. 13), Sir George King has brought the "Material for a Flora of the Malayan Peninsula" to the end of the Calycifloræ. The genus Begonia furnishes 19 species, of which 14 are new to science; most of these were collected in Perak, several at altitudes varying from 3000 to 7000 feet. Two new species of Mastixia are also described. As in the case of the Thalamifloræ and Discifloræ, a complete list of Calycifloral species has been published separately.

THE possibilities of pitcher plants as a trap for catching the American cockroach, *Blatta americana*, are pointed out in the October *Bulletin* of the Trinidad Botanical Department. Planted amongst orchids, they may materially help the cultivator to keep this pest in check, and are more especially suitable since they require similar conditions of heat and moisture. A note on the "Nitrogen Content of Flowers" emphasises the manurial value of those of the Immortelle, and Nicaragua shade plants which are sown amongst cacao plants. A new fruit obtained from the Bocas Islands and provisionally determined by the Kew authorities as *Anamomis esculenta*, judging from its flavour and aroma, seems likely to furnish good table fruit.

THERE is a strong physiological tendency displayed in the *Bulletin* of the College of Agriculture connected with Tokyo University. Several papers by Mr. K. Aso deal with the action of certain poisonous substances when supplied as food to seedlings. Salts of manganese, even in weak solutions, have an injurious effect, but if the solution is diluted to contain about 0·002 per cent. of the salt, then the result is stimulating. Similar stimulating effects were obtained with very dilute solutions of other poisonous salts. The same author contributes a suggestive paper on the oxidising enzymes in plants. Mr. M. Toyonaga, on the animal side, obtains results which are in keeping with Prof. O. Loew's hypothesis that the amount of calcium varies with the size of the nucleus.

WE have received a copy of vol. v. No. 1 of the *Bulletin* of the College of Agriculture at Tokio, which, among other contents, includes a memoir on the embryology of silkworms, by Mr. K. Toyama.

IN the November issue of the *American Naturalist*, Prof. B. Dean continues the discussion of the origin of vertebrate limbs—this time from the point of view of the flotation and balancing of the body in the sharks. It is concluded that the pectoral, and not the pelvic, fins have shifted their position with the advance of development, in accordance with the exigencies of the physiological factors referred to, and it is urged that this affords strong evidence in favour of the lateral fold theory.

WE have to chronicle the appearance of a new biological serial, *Broteria*, issued by the College of St. Fiel, Lisbon, and named in honour of the celebrated Lusitanian botanist, Dr. F. d'Avellar Brotero, who died in 1887. Although the new journal will embrace biological subjects of any kind, its special object is the fauna and flora of the district immediately surrounding the College of St. Fiel. In addition to a number of papers not specially connected with the area in question, the present issue contains one on the Lepidoptera of St. Fiel.

THE Manchester Museum has issued a second edition, revised and enlarged by Dr. Hickson, of Prof. Milnes Marshall's admirable descriptive catalogue of the series of embryological models in the collection. Since the appearance of the first edition, the development of the torpedo has been added to the series. Number 9 of *Notes* from the Manchester Museum is devoted to observations on the nomenclature and identification of the British cephalopods, by Mr. W. E. Hoyle, reprinted from the *Journal of Conchology*. The author shows that the substitution of the name Polypus for the familiar Octopus, although much to be regretted, is inevitable, unless priority in nomenclature is to be altogether discarded.

"THE Solution of the Eel Question" is the title of a highly interesting paper, by Dr. C. H. Eigenmann, published in vol. xxiii. of the *Transactions* of the American Microscopical Society. After a summary of the investigations and discoveries of Grassi and Colandruccio in Italy in regard to the developmental history of the European eel, the author records the discovery of the larva ("Leptocephalus") of the American eel—a species which differs from its Old-World relative, both in the adult and immature condition, by the smaller number of vertebræ. In August, 1900, Dr. Eigenmann had the opportunity of examining some eels' eggs from the surface of the Gulf Stream—the first taken elsewhere than in Italy—which there is every reason for regarding as those of the conger-eel. To the larval form of the American eel, the author—somewhat unnecessarily, in our opinion—applies the name *Leptocephalus grassii*. In discussing the question whether eels ever breed in fresh water, the author states that while there is nothing inherently impossible in this, yet no decisive evidence of its occurrence has been hitherto recorded. No eels' eggs have at present been taken in fresh water, and the statement that eels found in land-locked basins must of necessity breed there is by no means conclusive.

WE have received a copy of *The Scientific Roll and Magazine of Systematised Notes* (Bacteria, vol. i. No. 6), conducted by Mr. Alexander Ramsay. It contains a few notes on various bacteriological subjects culled from various authors, and an essay on specific descriptions.

IN its issue for November 29, the *Lancet* publishes as a supplement an exhaustive account of the manufacture and nature of Cognac brandy. A number of analyses are given showing how brandy differs from other spirits and indicating how the genuine may be distinguished from the spurious. The former is the product of distillation and maturation of a grape wine, the latter is derived from potato or grain spirit. The subject is of considerable importance from a medicinal point of view.

THE Public Health Department of the City of London directs attention (Report of the Medical Officer of Health, No. 52) to the filthy and dangerous habit of indiscriminate spitting, the chief source, probably, of tuberculous infection. Many cities in the United States, Canada, Australia and in Europe have made the habit a penal offence, and the Corporations of Liverpool, Manchester and Glasgow and the County Council of Glamorgan have bye-laws prohibiting it in public places. The Medical Officer for the City suggests that similar powers should be obtained by the Corporation of London for dealing with it.

NEW editions have been published of "Palæontology, Invertebrate," by Mr. Henry Woods (Cambridge University Press) and "Maps, their Uses and Construction," by Mr. G. James Morrison (Edward Stanford). The former is the third edition and Mr. Morrison's book is a second edition, which has been revised and enlarged.

THE twenty-fourth annual volume of the *Proceedings* of the United States National Museum, published under the direction of the Smithsonian Institution, contains, like all its predecessors, an abundance of valuable information on anthropological, biological and geological subjects. It is impossible in this place to refer to each of the separate contributions. Messrs. Jordan and Snyder review many classes of the fishes of Japan, separate papers being given to the discobolous, gobioid, gymnodont, hypostomide, lophobranchiate, labroid, salmonoid and trachinoid fishes. Messrs. Wirt Robinson and M. W. Lyon provide an annotated list of mammals collected in the vicinity of La Guaira, Venezuela, while Dr. Leonhard Stejneger deals with the batrachians and reptiles of the same locality. In another paper, the last named author describes a new bullfrog from Florida and the Gulf Coast. Mr. D. White gives an account of two new species of algæ of the genus Buthotrephis, from the Upper Silurian of Indiana. The fossil fresh-water shells of the Colorado desert form the subject of a paper by Dr. R. Stearns. The humming-birds of Ecuador and Colombia are catalogued by Mr. H. C. Oberholser. Illustrations and descriptions of new, unfigured or imperfectly known shells, chiefly American, in the U.S. National Museum are given by Mr. W. H. Dall. The larks of the genus Otocoris are described in detail by Mr. H. C. Oberholser. Many of the papers are accompanied by numerous admirable illustrations, those connected with Mr. Oberholser's paper being especially good.

THE additions to the Zoological Society's Gardens during the past week include a Patas Monkey (*Cercopithecus patas*) from West Africa, presented by Mr. E. Chaplin; a Virginian Eagle Owl (*Bubo virginianus*), a Mexican Eared Owl (*Asio mexicanus*) from Argentina, presented by Miss Irene Thornton; a Graceful Ground Dove (*Geopelia cuneata*) from Australia, presented by Miss Cooper; a Glass Snake (*Ophiosaurus apus*) European, presented by Mr. C. H. Rawlins; a Derbian Wallaby (*Macropus derbianus*) from Australia, deposited; four Black-necked Swans (*Cygnus nigricollis*) from Antarctic America, received in exchange.

OUR ASTRONOMICAL COLUMN.

NEW COMET 1902 *d* (GIACOBINI).—A telegram from Kiel, dated December 3, announces that the fourth new comet of this year was discovered by M. Giacobini at Nice on December 2d. 12h. Its position at 10h. 0m. (Nice M.T.) was R.A. = 7h. 17m. ·6, Dec. = 1° 58′ S., and it is moving in a north-westerly direction. A second telegram, dated December 4, says that the comet was observed by Herr Graff at Hamburg on December 3d. 11h. ·5, and its position for 15h. 0m. (Hamburg M.T.) was R.A. = 7h. 17m. ·4, Dec. = 1° 51′ S. The daily movement in declination is + 3′, and the projected path of the comet passes near to the border line between the constellations Gemini and Orion.

THE VARIABILITY OF α ORIONIS.—From an examination of his observations of the comparative magnitudes of Betelgeux and β Orionis which he has made during this year, Herr J. Plassman has confirmed the recent variation of magnitude in the former star, and he considers that the peculiarities of the variations merit further and continuous attention on the part of variable-star observers (*Astronomische Nachrichten*, No. 3830).

ACTIVITY OF THE LUNAR CRATER LINNÉ.—In *Circular* No. 67 of the Harvard College Observatory, Prof. E. C. Pickering gives the micrometric measures of the bright spot surrounding Linné which were made at Harvard by Prof. W. H. Pickering, using the 15-inch equatorial, before and after the passage of the earth's shadow in the eclipse of October 16.

These measures show that the bright spot has materially increased in size since similar measures were made in 1898 and 1899, and, further, that the change in size during the passage of the umbra was surprisingly great, so great that Prof. W. H. Pickering found it necessary to reassure himself that the object he was measuring was indeed Linné. This increase of size amounted to 2″·75, instead of 0″·14 obtained by the same observer during the eclipse of 1899 (*Popular Astronomy*, vol. viii. p. 58).

Prof. E. C. Pickering attributes the change in the normal size to increased activity on the part of the crater, and the large increase of diameter during the eclipse to the fact that, owing to this increased activity, there was on this occasion more moisture around the crater to condense.

The increase in normal size was confirmed by measures made on October 20, when the spot had begun to shrink owing to the increased amount of evaporation in the fierce sunlight, for the value obtained then (4″·61) was sensibly larger than that obtained (3″·41) during a similar phase in 1898.

REDETERMINATIONS OF THE VELOCITY OF LIGHT AND THE SOLAR PARALLAX.—A communication from M. Perrotin to No. 21 of the *Comptes rendus* describes the experiments which have been made recently, at the Observatory of Nice, to redetermine with greater accuracy the velocity of light, using the toothed-wheel method of Fizeau under improved conditions.

In previous experiments, the beam of light was made to travel a distance of 12km. (7·452 miles) and back, but in the recent experiments it was reflected from a mirror placed at a distance of 46km. (28·566 miles) from the source, an objective of 0·76m. diameter being used at the plane of emission and one of 0·38m. diameter as the collimator.

As a result of 1109 observations, the final value obtained for the velocity was 299,880km. (about 186,225·5 miles) per second, and the probable error is less than 50km. per second.

In addition, M. Perrotin also gives the final value obtained for the solar parallax, from observations of the planet Eros, made at Nice, as 8″·805 ± 0″·011, and from this deduces a value of 20″·465 for the "constant of aberration," thus confirming the value adopted by the International Astronomical Conference of 1896.

THE "ANNUAIRE ASTRONOMIQUE."—This year-book of astronomy for 1903, compiled by M. Camille Flammarion and published at the low price of 1·50 francs, is one of the most complete and useful books of its kind. It gives practically all the data required by the amateur astronomer or meteorologist, amongst which may be mentioned the solar, lunar and planetary elements for the year, the various phenomena such as eclipses, occultations, meteors, comets, &c., tables of the positions, distances and proper motions of the brighter stars, particulars of double stars, many useful meteorological tables, and a valuable *résumé* of the more important astronomical and meteorological events of 1902, the whole being freely illustrated by interesting photographs and curves.

METEOROLOGY AT GREAT ALTITUDES.[1]

AN International Aeronautical Congress was held at Berlin, May 20 to 24, 1902, on the occasion of the third meeting of the International Committee for Scientific Aëronautics, appointed by the Paris Meteorological Conference of 1896. Of this committee there were present the president, Prof. Hergesell, of Strasburg, Prof. Assmann and Mr. Berson, of Berlin, General

[1] Abridged from a Report contributed by Mr. A. Lawrence Rotch to the U.S. *Monthly Weather Review* for July.

Rykatchef and Colonel Kowanko, of St. Petersburg, Prof. Cailletet and M. Teisserenc de Bort, of Paris, and the writer, who is the American member. There were also present at the Congress, by special invitation, about one hundred military and civil aëronauts and representatives of meteorological institutions, the writer representing the United States Weather Bureau by request of its chief.

The opening of the Congress in the great hall of the Reichstag building was a brilliant event. Prince Frederick Henry of Prussia appeared for the Emperor of Germany. Both the Imperial and the Prussian Governments were represented, and the chief European nations, except France, sent the commanders or officers of their military balloon corps. After the usual formal greetings, the representative of the Prussian Minister of Instruction spoke as follows:—

"The Royal Government is much impressed with the importance and necessity of an exchange of ideas between the savants of all nations in matters concerning meteorology and terrestrial magnetism, since international cooperation in these branches of science is the indispensable forerunner of progress. This was indeed recognised as early as 1780, by the founding on German soil of the 'Societas meteorologica Palatina,' which undertook the task of beginning systematic weather observations in Europe, with the hope of extending them to other parts of the world. On account of the existing state of affairs, its efforts were of short duration and for a long time savants were allowed to labour independently, but with the foundation of magnetic investigations by Gauss and Weber, the sagacious idea of organisation acquired new life and pressed for realisation, especially through the development of navigation, which has the greatest interest in the accurate observation of weather phenomena on the ocean. The Antarctic discoveries of James Ross, and the successful efforts of American navigators to shorten ocean voyages, gave a new impulse, and so there arose the proposition of organising a meteorological service at the first congress of the maritime nations held at Brussels in 1854, although it was not until 1873, during the Vienna Exposition, that the first meteorological congress convened there laid the foundation of an international weather service. The international committee, appointed at that time, met at first annually, but later at intervals of two or three years. With its increasing activity, the necessity of dividing the work manifested itself, and thus special commissions were formed, of which one meets here to-day and whose third gathering will probably be as fruitful as its preceding meetings. In a field where there is only interest in research, may the bonds uniting the representatives of cultured nations ever become closer!"

In the name of the Prussian Meteorological Institute, its director, Dr. von Bezold, remarked that early investigators perceived the importance of aëronautics for meteorological researches. "When Charles, the inventor of the hydrogen balloon, made his first ascension in 1783, he took with him a barometer and a thermometer, as did the American aëronaut (Jeffries), who ascended from London during the next year. It was not until very lately that Germany took part in this work, or about the year 1880, but then, with an instrument markedly superior, namely, Assmann's aspiration-psychrometer, and through the munificence of the German Emperor, she was enabled to carry out the work on a large scale. For the second time, the representatives of scientific aëronautics now meet on German soil and thereby recognise the importance of our efforts. But much indeed has been done for this new research by M. Teisserenc de Bort at Trappes, near Paris, through the perfection of the *ballon-sonde*, the unmanned balloon carrying self-recording instruments, and by Mr. Rotch, of Blue Hill, through his application of kites. Both methods are so good that by their use a great impetus has been given to meteorological research, whereby it is easily understood that there should be uniform rules for their employment. Looking backward, it may be said that the international meetings for the organisation of meteorological research, in 1854 at Brussels, in 1873 at Vienna and in 1879 at Rome, are landmarks in the progress of the science, and that when, in September, 1896, the International Committee for Scientific Aëronautics was appointed, the plan had been so well considered and the technical necessity was so evident that there was entire unanimity in the deliberations and resolutions. The originator of the idea of the unmanned balloon was the late Gaston Tissandier, who enthusiastically explained the scheme to the speaker in 1886, although nearly ten years elapsed before its realisation. This work will be fruitful, for wind and clouds have no political boundaries and the sun belongs to us all. Consequently, we are all striving, for various reasons, toward the same goal, and the motto *viribus unitis* will be, as ever, the decisive measure of the result."

Prof. Cailletet, of Paris, responded for the foreigners present, and then Prof. Hergesell, after thanking the preceding speakers, said, in the course of his remarks:—

"Everywhere—in Paris, Strasburg, Munich, St. Petersburg and Berlin—aeronautical experiments for the scientific exploration of the atmosphere had taken place, and since a general wish was expressed to unite the separate efforts in a common cause, a favourable time to do this seemed to be in the autumn of 1896 at the conference in Paris of the directors of the meteorological institutes. France, the cradle of aeronautics, was the chosen ground, because there, independently of the German and Russian experiments, a most promising method of investigation had been developed that had already produced good results; for the French experimenters, Colonel Charles Renard and Messrs. Hermite and Besançon, all members of our Commission, had simultaneously put into execution the plan of exploring the highest strata of the atmosphere with free balloons carrying only self-recording instruments. Not the least service of our Commission has been to render the method of unmanned balloons comparable with the exact measurements in manned balloons as they are made in Berlin. During our first meeting, in April, 1898, at Strasburg, the difficult problem of obtaining a uniform instrumental equipment was solved in a general way. Since then, our manned balloons, here and abroad, carry the aspiration-psychrometer, which Dr. Assmann, in cooperation with the late Captain von Sigsfeld, has devised, and the unmanned balloons are provided with the normal registration apparatus which the indefatigable Teisserenc de Bort has constructed so skilfully. The registration balloon from that time has been the most powerful tool in dynamical meteorology and has furnished astounding data for the cold atmospheric strata up to a height of 20 kilometres, which are confirmed to a height exceeding 10 kilometres by the ascensions of the brave Berlin aeronauts, Berson and Süring, who have ascended so far in these regions. Since November, 1900, on the first Thursday of every month, simultaneous ascensions have occurred in Paris, Strasburg, Munich, Berlin, Vienna, St. Petersburg and Moscow, and on May 5, 1902, the 213th registration balloon of the International Commission was sent up. The observations have proved that the temperature does not steadily decrease upward, but that strata exist which often possess great differences of temperature. This stratification is one of the most important objects of the present investigation. And the future? Systematic meteorological research is at present carried on over only a small portion of the globe. Even in Europe, in the north there is lacking Scandinavia, and in the south Italy and Spain; but the presence of representatives of these countries at our meeting gives the hope of speedy cooperation. A plan for a meteorological cruise of a steamer to fly kites will also be discussed, for the meteorological exploration of the Tropics must be extended, and the participation of England in our endeavours gives us hope that India may be claimed as a region for investigation. *Per aspera ad astra*—that may be setting our goal too high, but, *per aspera ad altas et ignotas regiones*, up to the regions which hide the great secret where the weather comes from—that we certainly should fix as our goal."

At the second meeting, General Rykatchef, director of the Central Physical Observatory at St. Petersburg, spoke on the preliminary results attained with kites, *ballons-sondes* and manned balloons during the past five years in Russia. Scientific aeronautics in Russia date only from 1899, with the exception of some years of preparatory work. Still, there have been a large number of ascensions: 13 of the 60 kite-flights were above 3000 metres, while the *ballons-sondes* reached 14,200 metres. The inclement climate of Russia occasions many unusual difficulties, for instance, the kite wire on the reel becomes thickly coated with frost, rendering the unwinding difficult, or both wire and kites in the air are so thickly incrusted with frost work (five millimetres or more) that the kites often fall to the ground. Kites were used chiefly at the stations in Pavlovsk and St. Petersburg, and thereby special details were obtained in the lower strata of the diurnal and annual influence on the vertical decrease of temperature up to 3000 metres. It was found that in summer and during the daytime the decrease of temperature with increasing height proceeds more rapidly, and, on the contrary, that in winter

and during the night hours there are large inversions of temperature. In anticyclones, large inversions occur in the lower strata and a rapid decrease of temperature in the higher strata. General Rykatchef exhibited an anemometer, constructed by his assistant, Mr. Kusnetzof, for the registration of wind pressure during kite flights. The instrument has bridled Robinson cups which act like a dynamometer and record the gusts of wind on a revolving drum. In closing, the speaker announced that the Czar had given a considerable sum of money for the continuation of this investigation of the different strata of the atmosphere in Russia by means of balloons and kites.

M. Teisserenc de Bort, of Paris, presented the results of his observations of the decrease of temperature in the high atmosphere, as obtained from the ascensions of 258 *ballons-sondes*, which had reached or exceeded 11,000 metres, the total number of ascensions being 540, all of which were made at night to avoid the effect of insolation. The concordant and remarkable result is that, in the layer between 8000 and 9000 metres, the decrease of temperature becomes slower, ceasing entirely at 11,000 metres, while above that height a warming may set in, with fluctuations of 1° to 3° centigrade, making the temperature here on the average nearly constant. In the summer, this isothermal layer apears to lie somewhat higher, or between 13,000 and 14,000 metres. It is lower during the prevalence of a depression, but 4000 metres higher during a high pressure, so that the zone exceeds the height of the cirrus clouds. The lowest temperatures, occurring in a high pressure, were −67° and −72°, but in March the exceptionally low temperature of −75° centigrade was observed. Whether the absolute minimum of temperature has been reached here requires further proof, and as to the cause of this striking phenomenon there are only conjectures. Have we at these great heights aërial conditions working on a grand scale, where the cyclonic whirls of the lower atmosphere do not penetrate and the currents flow uninterruptedly?

Prof. Assmann said that the observations of the Berlin Aëronautical Observatory, although obtained by a somewhat different method, led to the same conclusion as that which had been reached at Trappes. Above 10,000 metres, the temperature oscillates and does not appear to decrease, although beyond the variable stratum, at 17,000 metres, and recently as high as 19,500 metres, the temperature was again found to decrease, so that the possibility of an absolute minimum of temperature is by no means excluded. The Berlin observations were executed with specially constructed balloons of Para rubber, which entirely avoided in the daytime the influence of solar radiation on the instrument, which was enclosed in double polished tubes.

Prof. Palazzo, Director of the Central Meteorological Office at Rome, announced that Italy would now participate in the international scientific exploration of the atmosphere. Through the aid of the Minister of Agriculture, three stations for kites are proposed; one on Mount Cimone (2165 metres), another on Etna (2942 metres) and a third outside of Rome, near the Fort of Monte Mario. The Minister of War has ordered that the ascensions by officers of the balloon corps shall take place on the days of the international ascents. Information was given about the observatory for the study of the physics of the atmosphere, now in construction on Monte Rosa at a height of 4560 metres, which is expected to be completed next summer. In connection with this communication, there was a discussion concerning the interest of scientific aëronautics in physiological investigations, which will form an important part of the work of the high-work observatory mentioned.

Prof. Assmann, Director of the Aëronautical Observatory of the Prussian Meteorological Institute, described his registration balloon of caoutchouc or Para rubber, which was one of the novelties of the meeting. The ordinary *ballon-sonde*, made of silk or paper and open at the bottom, has the great disadvantage that, when it approaches equilibrium in the upper strata of the atmosphere, its velocity of ascent decreases and the effect of insolation on the thermograph becomes greater, without it being possible to determine afterwards the place where the solar disturbance began during the ascent or where it disappeared during the descent; in fact, it is only in certain cases that we can distinguish between the insolation influence and the curious thermal anomalies that have been described by Teisserenc de Bort and Hergesell. The use of a closed balloon made of elastic material has this advantage, that in proportion as the enclosed gas expands, the ascensional force is increased, so that the balloon rises faster with augmenting height until it bursts, and then falls to the ground with diminishing velocity, because checked by a parachute. The meteorograph of Prof. Assmann has no clock movement, the time being unimportant; but a disc is turned by the metallic thermometer while the barometer draws a pen horizontally across the disc, and so the spiral curve indicates heights and corresponding temperatures. The apparatus exhibited weighed but 380 grams, and with the protecting basket 500 grams. Since ink would freeze at great elevations, the trace is made by a pen containing a solution of saltpetre, which writes on the disc coated with lampblack, treated with a solution of "tonsol." The chemical reaction gives a red trace that cannot be obliterated by handling or by immersion in water. The time required for an ascent to 15,000 metres is about one hour and for the descent two hours, so that the balloons do not travel very far and are usually recovered within three days. The diameter of the envelope at the start is 1 or 2 metres only, and it does not require to be completely filled with hydrogen to exert the necessary initial lift of 2 or 3 kilograms.

Dr. Valentin, of Vienna, spoke on the sluggishness of thermographs in registration balloons. Prof. Hergesell believed that it was better to employ the most sensitive and accurate thermometers rather than to try to determine the corrections for sluggishness. He exhibited such an instrument, as did M. Teisserenc de Bort. The French instrument has the Bourdon tube insulated by a block of hard rubber, which prevents the injurious conduction of heat. Comparisons between an instrument insulated in this way and one not insulated gave differences which increased with the height of the balloon and at 12,000 to 14,000 metres reached 6°, an amount that justified the insulation.

At the third meeting, the subject of kites and kite stations was opened with a paper by the writer on the exploration of the atmosphere over the ocean. The use of the kite on land is limited to favourable circumstances, since the wind must have a velocity of at least 5 or 6 metres per second to raise the kites and cannot exceed a certain maximum strength without endangering the wire by an excessive pull. At sea, however, the motion of a steamer at a velocity of 10 or 12 knots will almost always produce a suitable kite wind, if it does not already exist. In order to demonstrate this, in August, 1901, the writer crossed the North Atlantic on a steamer and found five out of eight days suitable for flying kites. Only on one day was the relative wind too light and on two days too strong, but the wind would always have been favourable had it been possible to alter the course of the vessel. These successful results led the writer to propose a meteorological kite expedition to the trade wind and equatorial regions of the Atlantic Ocean, where almost nothing is known of the upper currents. To defray part of the expense, application has been made to the Carnegie Institution for a grant of 10,000 dollars, but it was considered that the recommendation of the present Congress might aid in securing favourable action. Applause showed the approval of the meeting, which was voiced by Drs. von Bezold and Hergesell. The former, especially, pointed out the importance and the pressing need of meteorological observations over the ocean, where, in consequence of other methods of warming and cooling the air, very different conditions must exist than prevail over the land, and our ignorance of them is no longer to be tolerated. Prof. Köppen, of Hamburg, expressed himself in a similar manner, and made the interesting announcement that, according to the programme of the Scandinavian Hydrographic Congress to explore the Baltic and North seas in the interest of the fisheries, four cruises a year were proposed on which meteorologists would be given an opportunity to study the atmosphere above these seas. Prof. Wagner, of the University of Göttingen, said that the Göttingen Society of Sciences had, at the request of the Aëronautical Committee, furnished the geophysical expedition which was sent to Samoa about a year ago under the leadership of Dr. Tetens with kites and instruments, in order to obtain meteorological observations above that island and on the return voyage over the Pacific Ocean. Dr. Hergesell mentioned that on the Lake of Constance meteorological kite flights were to be undertaken, Count von Zeppelin furnishing the vessel and the meteorological service of Alsace-Lorraine the apparatus. General Rykatchef promised, on the part of the Russian Government, that similar observations would be executed over the northern portion of the Baltic as well as over the Black Sea. On the motion of Dr. Hergesell, the plan of Mr. Rotch for a meteorological

kite-expedition in the South Atlantic was fully approved, and the hope was expressed that, with the aid of Government funds, the project might be realised in the near future. Mr. Berson remarked that it was of the greatest importance that the British as well as the Dutch Governments should encourage meteorological observations in the monsoon region, and Major Trollope, speaking for Great Britain, said that he would endeavour to have this done.

M. Teisserenc de Bort showed a diagram of the results obtained from continuous soundings of the atmosphere, or those made as frequently as possible at his observatory at Trappes, viz., on thirty-six days in January and February, 1901, when kites and registration balloons (*ballons-sondes*) were sent almost daily into the higher atmosphere to an extreme height of 12,000 metres. The plotted results throw doubt on the assumption that the barometric depressions bring higher temperatures and the barometric maxima lower temperatures, and give an interesting demonstration of the diversity and complexity of the atmospheric phenomena of which it is the aim of international aëronautics to ascertain the laws.

The fourth meeting was principally occupied with the subject of high ascents, and an apparatus for breathing oxygen at great altitudes was shown by Prof. Cailletet.

Dr. Süring spoke on the ascension which he had made with Mr. Berson on July 31, 1901, to the height of 10,800 metres, the greatest height yet reached by man. He insisted upon the importance of such high ascents to control the observations otherwise obtained and to make those that require direct vision. Especially are the strata from 5000 to 10,000 metres not yet adequately explored, and for weather changes they are of great importance, as is indicated by the scarcity of clouds near 4000 metres and above 6000 metres.

Lieutenant von Lucanus, in the name of the German Ornithological Society, asked aëronauts to observe the various heights at which birds are found. It is now supposed that the height above the ground at which birds fly does not generally exceed 400 metres, and only occasionally reaches 2000 metres, the zone usually remaining below the lower clouds. Still, much uncertainty prevails concerning the tracks of birds, and especially the heights of flights, and information is greatly desired.

The fifth session was mostly devoted to a discussion of observations of atmospheric electricity and terrestrial magnetism in balloons. Prof. Hergesell explained that electrical measurements are of such vital interest that the academies of Berlin, Munich, Göttingen, Leipzig and Vienna were to have been represented at this meeting by Profs. von Bezold, Ebert, Wagner, Wiener and Exner. The latter, who is the Nestor of this branch of physics, was prevented from attending, but Prof. Elster, of Wolfenbüttel, was present among the experts. Prof. Ebert, of Munich, said that constituents containing electrical charges had been found recently in the air through their physical properties. These carriers of electricity are called "ions," or, more correctly, "electrons." At the earth's surface, their presence may be shown by the dissipation apparatus of Elster and Geitel, and the smallest quantity of electricity may be recorded by means of an electrometer. The speaker had adapted this apparatus for use in balloons, and, by employing an aspirator, a fixed quantity of air could be drawn over the dissipating body and absolute measurements made of the amount of free electricity contained in a cubic metre of air. It is of importance in geophysics to know how the capacity of the air for positive and negative electrons varies with altitude, and therefore the speaker had made such determinations, finding near the earth many more positive than negative electrons, but whether this is a result of the negatively charged earth is uncertain. In the high strata, the inequality tends to disappear, but considerations that throw doubt on the balloon observations relate partly to the electrical discharges produced by the ultra-violet light rays and partly to the indeterminate moment of aspiration in a rising or falling balloon. Prof. Ebert considered the cooperation of aëronauts valuable, and cited as a result of the investigation in the Alps that in the foehn wind an excess of positive electrons is found, and this disturbance of the electrical equilibrium perhaps may cause the foehn sickness. Prof. Elster described two experiments that proved the existence of the electrons, one being the radiation of Becquerel rays after two hours from an insolated and stretched copper wire charged with 2000 volts. It was agreed by both experts that the cleaner and clearer the air the more electrons it contains.

Before closing the Congress, the resolutions proposed, after undergoing certain modifications, were adopted by the committee in executive session, the Congress itself being only a consulting and advisory body. Besides the resolutions mentioned already, it was determined that the international ascents of balloons and kites during the next year should take place, as has been the case this year, on the first Thursday of every month, and that at least one of the *ballons-sondes* liberated at any station should be sent up one hour before sunrise in order that its records may not be affected by solar radiation, and also that the balloon may be seen when it falls to earth in the early morning. The Richard thermograph, with Teisserenc de Bort's insulating device, should be used, and the Hergesell instrument having a tube of German silver, instead of the Bourbon tube filled with alcohol, was also recommended on account of its sensitiveness and durability. Ascensions at other hours and with different apparatus are discretionary. The president, Prof. Hergesell, in summing up the results of the Congress, which he regarded as eminently satisfactory, laid special importance on the meteorological kite flights that were proposed over seas, lakes and mountains, and hoped that the British Government, by similar work in India, would help in the investigation of the great Asiatic monsoon region. A grant of money was requested from the German Government to enable the Prussian Meteorological Institute to cooperate with the writer in his proposed investigation of the atmosphere over the Atlantic Ocean. It was announced that in order to facilitate international researches in scientific aeronautics, the formation of an organisation, sustained by the various European nations, would be attempted.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—AN election will be held at Brasenose College in March, 1903, to an ordinary fellowship, of the value of 200*l.* a year, tenable for seven years, after an examination in the subjects recognised in the Honour School of Animal Physiology. Weight will be attached to work exhibiting research in some subject of physiological study.

The electors to Dr. Lee's readership in chemistry will appoint a reader in January, 1903, and they invite candidates to submit their names and qualifications before January 1. The reader must lecture in two at least of the three University terms, and, in addition to the duties performed for the University, he may be required, as an official student of Christ Church, to take part in the educational work of the house by giving lectures or other instruction in chemistry and directing the work of the chemical laboratory.

Convocation has granted 200*l.* to the Wykeham professor of physics to defray the expenses of fittings for his laboratory.

CAMBRIDGE.—The reader in geography and the lecturers in ethnology and geology have arranged for a series of lectures and practical courses to serve as a training for persons wishing to undertake exploration or desirous of contributing to our knowledge of foreign countries. The series will be held during the Lent term, and will include history of geographical discovery, principles of physical geography, map-making and map-reading, and geography of Europe, by Mr. Oldham; anthropogeography, practical ethnology, by Prof. Haddon; geomorphology and geology, by Mr. Marr; plane-table and photographic surveying, by Mr. Garwood; and elementary astronomical surveying, by Mr. Hinks. The courses will be open to members of the University and others. The fee for all is 3*l.* 3*s.* Further particulars may be obtained from Prof. Haddon, Museum of Archæology, Cambridge.

A syndicate has been appointed to consider what changes, if any, are desirable in the regulations that affect the mathematical portions of the pass examinations of the University, in particular of the previous examination. The members of the syndicate are:—The Vice-Chancellor, Mr. C. Smith, Prof. Forsyth, Dr. Hobson, Mr. W. L. Mollison, Mr. C. A. E. Pollock, Mr. W. Welsh, Prof. G. B. Mathews, Mr. S. Barnard, Mr. W. M. Coates, Mr. E. T. Whittaker and Mr. A. W. Siddons. It is probable that the syndicate will recommend changes analogous to those which have been introduced in connection with the University local examinations, especially as regards the dominance of Euclid.

THE council of University College, Liverpool, has appointed Major Ronald Ross, C.B., F.R.S., to the Sir Alfred Jones chair of tropical medicine and parasitology, recently founded with the aid of special subscriptions to the University fund.

AT a meeting of the general committee of the Principal Viriamu Jones memorial fund, recently held at University College, Cardiff, it was decided to raise a fund of 1000*l*. to erect a statue to the memory of the late principal. To carry out this object and to raise the necessary funds, an executive committee was appointed.

AT a meeting of business men of Manchester and district held on Monday, the Lord Mayor being in the chair, the following resolution was unanimously adopted:—"That the increasing competition and keenness of modern business life and its greater complexity call for a more thorough mental training of persons aspiring to be heads and managers of commercial and industrial establishments, and that this meeting heartily approves of the further development of the higher education bearing on commercial life now provided in the Owens College by the establishment of a Faculty of Commerce on the lines of the draft scheme now submitted."

THE prizes and certificates were presented to successful students of the Northampton Institute, Clerkenwell, on the evening of December 3, by the Lord Chancellor. The principal, Dr. Walmesley, reported a marked improvement during 1901 over the previous year in the number of medals and exhibitions gained in open competition by his students. Before the presentation of prizes, the Lord Chancellor said, in the course of a short address, that suitable technical education would enable the commerce of this country to achieve again the reputation which in some aspects had been diminished in modern times. In this matter, foreigners had been assisted by their Governments and had been provided with educational establishments at the expense of their countries.

THE fifth annual London conference of science teachers will be held on January 9 and 10, 1903, at the South-Western Polytechnic, Chelsea. At the first meeting, the chair will be taken by Mr. Henry Ward, chairman of the London Technical Education Board, and addresses will be delivered by Mr. Usherwood, on the experimental teaching of geometry, and by Mr. Frank Castle, on the teaching of workshop mathematics. Sir William Anson will preside at the second meeting, and addresses on the teaching of geometry will be given by Messrs. S. O. Andrews, W. D. Eggar and A. W. Siddons. Prof. Farmer, F.R.S., will be the chairman at the third meeting, when experimental plant physiology and the rational teaching of botany will be the subjects taken up by Mr. H. B. Lacey and Miss Lilian Clarke respectively. Prof. Callendar, F.R.S., will take the chair at the last meeting, when an address will be given by Mr. Newth on experimental illustration in the teaching of chemistry, and one by Mr. Busbridge on making lantern slides. Free admission to the conference will be granted to as many teachers as the room will accommodate, and application for tickets should be made to Dr. Kimmins, Dame Armstrong House, Harrow-on-the-Hill, or to Mr. C. A. Buckmaster, 16 Heathfield Road, Mill Hill Park.

WE announced last week that the name of Sir John Williams, Bart., had been mentioned in connection with the vacancy caused by Sir Michael Foster's resignation of his seat in Parliament as member for London University. Since then we have received a circular containing the invitation sent by a committee of graduates to Sir John Williams to become a candidate for the vacant seat, and the reply in which he accepts it. After referring to the new conditions of work of the reorganised University of London, Sir John remarks in his reply to the chairman of his committee, Sir J. F. Rotton:—"For the further development of the teaching side of the University and the realisation of our expectations with respect to its work, the creation of schools of original research is necessary. The gifts of generous donors do not and will not suffice to meet the expenses which they will entail, and I am of opinion that such schools form fitting objects of support from the State. Such establishments are a necessity for the growth of that scientific learning which is essential for the progress of trade and the prosperity of the country, as well as for the education of the community. Questions of public health—the prevention of epidemics, the securing of efficient vaccination, the housing of the people, the supply of unpolluted water, the disposal of refuse—engage the attention of Parliament from time to time; questions in the discussion of which the knowledge of those who have been trained in the laws of health and disease, and their application in practice, will prove of great value. To such I would give my earnest attention." Sir Philip Magnus has been asked by an influential body of graduates representing educational institutions to become a candidate for the seat, and has accepted the invitation. Both Sir John Williams and Sir Philip Magnus would give general support to the present Government as Unionists.

THE following announcements of gifts to higher education in the United States have been made in *Science* since the beginning of September:—Mrs. Phœbe Hearst's gifts for archæology and anthropology at the University of California amounted to 111,000 dollars during the last academic year. The University of Pennsylvania has received 100,000 dollars from Dr. E. W. and Clarence H. Clark for a chair in Assyriology, to which Dr. Hilprecht has been appointed. Dr. and Mrs. C. A. Herter, of New York City, have given 25,000 dollars to Johns Hopkins University. Dr. Howard A. Kelly has given 10,000 dollars for an extension of the gynæcological ward of the Johns Hopkins Hospital. Mr. John D. Rockefeller has offered to give 500,000 dollars to Teachers' College, Columbia University, on condition that the sum of 440,000 dollars be collected from other sources—190,000 dollars to pay the outstanding debts and 250,000 dollars for further endowment. The college has received from Mr. and Mrs. B. Everett Macy 175,800 dollars for the increase of the endowment funds and 98,709 dollars for the completion of the Horace Mann School. Princeton University receives 140,000 dollars under the will of the late Mrs. Susan Dod Brown. The bequest to the Princeton Theological Seminary made by Miss Mary Winthrop, of New York, amounted to 1,400,000 dollars. Yale University receives about 171,000 dollars as the residuary legatee of the estate of Mr. E. W. Southworth. The Ohio Wesleyan University receives 150,000 dollars under the will of the late Mr. Francis B. Loomis, of Cincinnati; and Vassar College receives 10,000 dollars by the will of the late Mr. Adolph Sutro, of San Francisco. Clark University will receive the sum of 1,577,000 dollars from the estate of the late Jonas G. Clark. This is in addition to the 500,000 dollars already paid on account of the collegiate department. These gifts and promises cover a period of three months and only include those known to have been made, yet they amount to nearly five million dollars, that is, about one million pounds.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, November 28.—Prof. S. P. Thompson, president, in the chair.—Prof. Perry read a paper on a slide-rule for powers of numbers. Soon after the reading of Mr. Lanchester's paper in 1895—the radial cursor: a new addition to the slide-rule—Prof. Perry made slides to assist in computing m^n, where m and n are any numbers. He then came to the conclusion that no great accuracy was obtainable; but on trying the method again, he has recently found that it is very convenient and sufficiently accurate for gas- and steam-engine work. These computations can be made with a table of values of log (log m) used in conjunction with an ordinary table of logarithms. In the rule exhibited, the D line is replaced by a scale such that the distance from the mark 10 to the mark m represents log (log m) to the same scale of measurement as that to which the distance from 1 to n on the C scale represents log n. The values of m range from 2 to 1000, and those of n from 1 to 10 or from 1 to ·1 used backwards. The author showed how, with one operation, the rule could be used to find the value of $m^{\frac{a}{n}}$, $m^{\frac{1}{n}}$, and the logarithm of any number to any base. If the answer on scale D is less than 2 or greater than 2000, or if the exponent n is negative, indirect methods involving two operations are necessary. Prof. Perry has replaced the ordinary D line by the log log scale, because in his opinion this line is the one least used by workers with the slide-rule. The use of the log log scale was described by Roget in 1814, and the author's object in bringing the matter forward lies in the fact that

Dr. Roget's paper seems to be almost unknown, and it is only in these modern days that the computations for which he invented the rule have to be frequently made.—Prof. H. L. Callendar exhibited a lecture experiment for the determination of the mechanical equivalent of heat. The experiment was carried out with a modified form of the apparatus exhibited and described by Prof. Callendar at the meeting of the Physical Society held on June 20.

Geological Society, November 19.—Prof. Charles Lapworth, F.R.S., president, in the chair.—The Semna Cataract or Rapid of the Nile, a study in river-erosion, by Dr. John Ball. Inscriptions placed on the rocks at Semna, between the second and third cataracts, under the twelfth and thirteenth dynasties, serve as a means of gauging the local changes due to river-erosion during a period of about 4200 years. Horner, in 1850, came to the conclusion that "the only hypothesis which could meet the requirements of the facts observed would be either the wearing away of a reef or barrier at the place in question—a process requiring too long a period—or the existence at some distant period of a dam or barrier, formed perhaps by a landslip of the banks, at some narrow gorge in the river's track below Semna." The author is in favour of the former explanation. Rapid erosion with the formation of pot-holes is observed to be now taking place, and the author calculates that if 200 cubic metres (approximately 500 tons) of rock per year has been removed from the barrier, the lowering of it would amount to 2 millimetres a year, or in 4200 years 7·9 metres, the depth of the present river below the lowest group of inscriptions dating from the time of Amenemhat III. The yearly discharge of the Nile past Semna is nearly 100,000 million tons of water, and the author considers that the removal of 500 tons of rock under existing conditions in a year is not only not impossible, but highly probable, as all this erosion only amounts to 5 milligrams of rock per ton of silt-laden water. This erosion is compared with the classic instance of the River Simeto in Sicily. At Assuan and Silsilla, the river has suffered considerable lowering within geologically recent times, probably brought about by the removal of long pre-existent hard barriers. The sluices of the new dam at Assuan may in the future give a quantitative determination of silt-erosion in granite, and it would appear to be not difficult to ascertain at Semna the rate of pot-holing. The formation of new pot-holes 1½ feet deep, in an artificial channel in rock in Sweden, has been observed to take place in eight or nine years, and the author hopes in future to attempt some measurements of this kind at Semna.—Geological notes on the North-West Provinces (Himalayan) of India, by Mr. Francis J. Stephens. The country examined extends in a north-westerly direction across the line of strike, from the borders of Nepal and South-eastern Kumaon to north of the Alakmunda River in the vicinity of Badrinath and the Marra Pass. The summary of the author's observations leads him to "suppose that there are at least three distinct limestone or calcareous series in Kumaon and Garhwal, and that schists and quartzites, with several isolated patches of granitic rock, form a large part of the remaining formations."—Tin and tourmaline, by Mr. Donald A. MacAlister. The author gives a possible explanation of the reactions by which tin oxide could be separated from solution in magmas containing alkaline borates.

Mineralogical Society, November 18.—Dr. Hugo Müller, F.R.S., president, in the chair.—Mr. F. E. Lamplough contributed a note on proustite crystals, on some of which an unusual trigonal pyramid {73$\bar{3}$} is the dominant form, and on others the pyramid {9$\bar{4}$4}. These forms are associated with r{100}, e{011}, v{20$\bar{1}$}, a{10$\bar{1}$}, and in one case with {$\bar{1}\bar{1}$.7.7.}.—Prof. W. J. Lewis described crystals of mispickel and iron pyrites from the Binnenthal, and crystals of quartz and sphene from the Ofenhorn.—Mr. R. H. Solly gave an account of various minerals from the Lengenbach, Binnenthal. These included large crystals of baumhauerite differing in habit from those previously described by him and exhibiting several new forms, an unique crystal of binnite weighing more than 8 grams, and fine specimens of dufrenoysite partially covered by minute crystals of seligmannite. On the latter, ten new forms were observed, and from measurements made on twelve brilliant crystals the axial ratios were determined to be $a:b:c = 0·92332:1:0·87338$. The presence of copper was detected and the streak was chocolate-brown. Mr. Solly also discussed the crystallography of a presumably new mineral from the Lengenbach, five minute but brilliant crystals of which were found on a crystal of rathite. In these crystals, no plane or axis of symmetry could be determined, and each crystal was grown in a different position.—Mr. G. F. Herbert Smith exhibited a special form of protractor, and described the method of using it for plotting poles on a sphere in gnomonic projection and for determining the angles between poles and between zones graphically from the diagram.—Mr. G. T. Prior discussed the connection between the molecular volumes and chemical composition of some crystallographically similar minerals. He pointed out the chemical relationships (similarity in form of the chemical molecule with approximately the same number of atoms) of the members of the hamlinite-beudantite-jarosite group of rhombohedral minerals and showed that the molecular volumes exhibited an approach to equality. In the case of several sets of crystallographically-similar minerals, it was found that when the chemical formulæ were made similar in form by taking suitable multiples of the simplest formulæ, then the molecular volumes calculated for these new formulæ were approximately equal. On this principle, from the crystallographic similarity of rutile to zircon, of anatase to calomel and of brookite to tantalite and wolfram, the following formulæ for the three forms of titanic acid were deduced, viz. rutile (Ti_2O_4), anatase (Ti_4O_8), brookite (Ti_6O_{12}).—Mr. Prior also contributed a note on phonolitic rocks from St. Helena and Ascension. These were compared with similar rocks from the Great Rift Valley and from Abyssinia, and the striking uniformity of the volcanic rocks of the African continent was pointed out. It was suggested that this was only a part of a wider generalisation according to which the volcanic eruptions of the great Atlantic volcanic chain (including its two transverse European branches and the minor chain down the east side of Africa) are characterised by the association of basalts and alkali-rich phonolitic rocks, whereas andesites are the prevailing lavas of the two great Pacific chains.—Mr. L. J. Spencer described the crystalline form of carbides and silicides of iron and manganese, crystals of which had been placed at his disposal by Mr. J. E. Stead. He showed that crystals of the metallurgical products, spiegeleisen, ferro-manganese and silico-ferro-manganese, of which the general chemical formula is $(Fe,Mn)_3(C,Si)$, are of two kinds—(1) rhombic with a prism-angle of 67½°; (2) anorthic with a prism-angle of about 60°.

Linnean Society, November 20.—Prof S. H. Vines, F.R.S., president, in the chair.—Mr. R. Morton Middleton, gave an account of the dissertation by Linnæus on *Siren lacertina*, annotated by the author, which he had found in a dealer's possession and since then had been presented to the Society by the treasurer.—Mr. W. C. Worsdell showed a series of anomalous virescent flowers of *Helenium autumnale*, six strong plants in the garden at Friar Park, Henley, the residence of the treasurer, being thus affected.—Mr. H. E. H. Smedley exhibited large wax models of the fossil seeds of *Stephanospermum akenioides* and Lagenostoma, the latter occurring in the Lower Coal-measures of Lancashire; he also showed a model of a recent Cycad for comparison.—Rev. T. R. R. Stebbing, F.R.S., V.P., having taken the chair, the president reminded the Society that exactly a year ago he had the honour of giving an account of some observations upon the action of the enzyme contained in the secretion of Nepenthes. That enzyme, he then explained, not only possesses the property of peptonising the higher proteids (*e.g.* fibrin), but is also proteolytic, decomposing the proteid molecule into non-proteid nitrogenous substances such as leucin and tryptophane. The proof of this is afforded by the fact that liquids containing proteids that have undergone digestion give the tryptophane reaction; that is, a pink or violet colour on the addition of chlorine-water. Since that time, many other plants have been investigated with the object of ascertaining, (1) whether or not a digestive enzyme were present, and (2) of determining the nature of its action. In almost all cases, the presence of a proteolytic enzyme has been demonstrated. The experiments definitely establish the fact that an enzyme which actively proteolyses the simpler forms of proteid is present in all parts of the plant-body. But the question as to the precise nature of this enzyme still remains to be answered. Where proteolysis is accompanied by peptonisation, it may be inferred that the enzyme is allied to the trypsin of the animal body. Where no peptonisation, but only proteolysis, can be detected, it seems probable that the enzyme is allied to the erepsin recently discovered by Cohnheim in the small intestine. Possibly more than one enzyme may be active in certain cases. The conclusions arrived at depend entirely upon the trust to be placed upon the tryptophane reaction as evidence of proteolysis. From what is

known as to its chemical composition and as to the conditions of its formation in digestion, there can be no doubt that tryptophane is a product of the disruption of the proteid molecule. The point that had more particularly to be determined was whether the substance giving the colour-reaction with chlorine in these experiments is really tryptophane. The isolation of tryptophane is a difficult process, and was not attempted. The chemical identity of the substance is, however, established by the fact that its chlorine compound was found to give the same absorption spectrum as does that of tryptophane, namely, a band in the green on the yellow side of the thallium line.—Mr. A. G. Tansley gave an account of the relation of histogenesis to tissue morphology, dealing with a few points bearing on the relation of histogenesis at the apex of the stem in the Pteridophyta to the morphology of the tissue regions in the adult stem.—Mr. L. A. Boodle followed with a paper entitled "Stelar Structure of Schizæa and other Ferns."

DUBLIN.

Royal Irish Academy, November 10.—Prof. R. Atkinson, president, in the chair.—Sir Robert Ball, F.R.S., communicated a paper on the reflection of screws and allied questions. Let there be any system of straight lines and take any arbitrary plane S. Let P be a point on one of the straight lines, and let fall a perpendicular PT upon the plane S. Produce PT to P′ so that P′T = PT. Then the point P′ is the reflection of P. If we repeat this process for every point of the original system of straight lines, we obtain the reflected figure. The fundamental theorem is as follows:—The reflection of two reciprocal screws also forms a reciprocal pair provided the signs of the pitches of both screws be changed. From this we deduce the following theorems: (1) The reflections of a set of coreciprocal screws also form a set of coreciprocals; (2) the reflection of an n-system of screws is also an n-system.—Dr. R. F. Scharff read a paper on the Atlantis problem. After dwelling upon the historical aspects concerning the former existence of a continent beyond the Strait of Gibraltar known to the ancients as "Atlantis," Dr. Scharff referred to the attempts which had been made to solve this problem from a faunistic point of view. He disagreed with Dr. Wallace in his opinion that the fauna of the Atlantic Islands had been derived from occasional means of dispersal, and contended that the origin of their fauna was mainly due to former land-connections with Portugal and Morocco. The paper also dealt with the wider question of the existence of a land-connection between the Old World and the New in the same latitudes, the author maintaining that such a land-bridge had persisted until Miocene times.—Prof. C. J. Joly read a note on the multi-linear quaternion function in relation to projective geometry. When a quaternion is interpreted as a point-symbol, the equation $p=fq$ represents the general homographic transformation in space from one set of points q to another set p, f being a linear quaternion function. Also if f' is the conjugate of f, the equations $Sq(f+f')q=0$, $Sq(f-f')q'=0$, represent the general quadric surface and the general linear complex. Starting from these results, which were communicated to the Academy last year, the author proposes to consider the bilinear function $f(pq)$. The equation $p=f(eq)$ represents a homographic transformation when e is regarded as a constant quaternion, and by varying e, a four-system of homographic transformations is obtained the properties of which may be easily studied. The equation $p=f(qq)$ represents the general quadratic transformation. From a bilinear function $f(pq)$, five other fundamental functions may be obtained; the first and second conjugates, viz. the conjugates with respect to p and to q; the *promutate* $f(qp)$, and its first and second conjugates. The equation $Sqf(qq)=0$ represents the general cubic surface, and associated with this surface are systems of linear complexes $Sef(pq)=Sef(qp)$, just as the linear complex and the quadric are connected with a single function. The trilinear function $f(pqr)$ leads to similar results. In particular, if a and b are two constant quaternions, the equation $p=f(a, b, q)$ represents the complete group of linear transformations, any particular transformation being determined by suitable values of a and b.

PARIS.

Academy of Sciences, December 1.—M. Bouquet de la Grye in the chair.—On the temperature of inflammation and on the combustion in oxygen of the three varieties of carbon, by M. Henri Moissan. The temperature at which carbon enters into active combustion with oxygen differs with the variety of carbon, being higher as the carbon is more polymerised. Diamond becomes incandescent in oxygen between 800° and 875° C., graphite between 650° and 700° C., amorphous carbon between 300° and 500° C., but in each case the visible combustion is preceded by a stage during which the carbon is oxidised, this action taking place with a velocity which decreases the lower the temperature. Amorphous carbon is slowly oxidised in either moist or dry oxygen at a temperature as low as 100° C. —Experimental researches on adrenaline, by MM. Ch. Bouchard and Henri Claude. Experiments carried out with rabbits showed that the injection of 0·5 milligram of adrenaline per kilogram of body weight, and in one case as little as 0·2 milligram, was rapidly fatal. The animals survived a dose of 0·1 mgr. per kilogram, and it was found possible, by gradually increasing the amount injected, to diminish the susceptibility to the toxic effects of the adrenaline.—The heart in its normal state and during pregnancy, by MM. Ch. Bouchard and Balthazard. The orthogonal projection of the heart was traced by the aid of the X-rays and a fluorescent screen in forty-nine subjects, and a preliminary table of the results is given.—Observations regarding physiological injections, by M. Yves Delage. The injection of colouring matters such as ammonium carminate and indigo carmine for localising with precision the excretory functions is regarded as being likely to lead to fallacious conclusions. The colouring matters used are not normal excretion products, and because in certain animals some of these substances are eliminated by the normal organs of secretion, it does not follow that this is always the case. The line of argument strictly followed out would even lead to the conclusion that the nervous system is excretory because it fixes methylene blue.—On the Laplace-Abel integral, by M. G. Mittag-Leffler.—On the conditions necessary for the stability of equilibrium of a viscous system, by M. P. Duhem.—The tracing of pressure curves, by M. E. Vallier.—M. Deslandres was elected a member in the section of astronomy in the place of the late M. Faye.—On some consequences of certain developments in series analogous with trigonometric expansions, by M. W. Stekloff.—On some congruences with several unknowns, by M. R. Levavasseur.—On a generalisation in continued fractions, by M. Auric.—On uniform transcendentals, defined by differential equations of the second order, by M. R. Liouville.—A method of evaluating temperatures in the thermodynamic centigrade scale, by M. Ponsot. The method suggested by M. Pellat requires the simultaneous measurement of three magnitudes, the electromotive force of a thermoelement, the Peltier effect at one of the junctions and the temperature of this junction in an ordinary thermometric scale. The method suggested by the author is simpler as the latter determination is dispensed with.—The acceleration of gravity on the mean parallel, by M. J. Collet.—On the composition of gaseous hydrates, by M. de Forcrand. By the application of the thermodynamical method indicated in previous papers by the author, the probable formulæ of the hydrates of various gases are calculated; in nearly all cases, the hydrate has six molecules of water.—The transformation of pyrophosphoric acid into orthophosphoric acid, by M. H. Giran. By cooling syrupy pyrophosphoric acid down to −10° C. for three months, the acid was obtained in the crystallised form, and this was used for new thermochemical determinations.—Manganese aluminate, by M. Em. Dufau. By heating a mixture of alumina and oxide of manganese in the electric furnace, an aluminate identical with that previously described by Ebelmen is obtained, which on analysis proved to have the composition Al_2O_4Mn. It formed clear yellow transparent octahedral crystals, and although stable under conditions of ordinary temperature, is readily oxidised when heated in contact with air.—On the estimation of manganese, by M. H. Baubigny. An account of the precautions required for the estimation of manganese in acid solution by means of ammonium persulphate.—The action of bromine and chlorine on the mononitro-veratrols, by M. H. Cousin. In this paper, the constitutional formulæ of a certain number of trisubstituted derivatives of pyrocatechol and its methyl esters are determined, and two new nitro-derivatives are described.—On the reduction of acetol, by M. Andre Kling. The action of several reducing agents upon acetol was studied under various conditions, and the results lead the author to conclude that the constitution usually assigned to this compound is not correct, and that its constitution is better explained by the formula $\underset{\diagdown O \diagup}{CH_3{\cdot}C(OH){\cdot}CH_2}$.—The action of

fatty amines upon the dibenzoate of ethylene, by M. Marcel Descudé.—The action of halogen esters upon ammonim thiosulphocarbamate, by M. Marcel Delépine.—On the ichthyological fauna of the fresh waters of Borneo, by M. Léon Vaillant.—On the fishes of the Chondrostome group in the fresh waters of France, by M. Louis Roule.—The morphological and anatomical variations presented by the gizzard in some Coleoptera, by M. L. Bordas.—On the polychætal annelids in fresh water, by M. Ch. Gravier. Excretion in the Cirripedes, by M. L. Bruntz.—The application of a character of ethological order to the natural classification, by M. L. Matruchot.—The distribution of sphærulins in vegetable families, by M. Louis Petit.—The present state of the volcano of Martinique, by M. Lacroix.—On the evolution of the spermatid in the *Notonecta glauca*, by MM. J. Pantel and R. de Sinéty.—On the presence of paranucleolar acid corpuscles in the cells of *Locus niger* and *Locus coerulens*, by M. G. Marinesco.—The ratio of the weight of the liver to the total weight of the animal, by M. E. Maurel. Adult animals have less liver per kilogram weight than young animals of the same species. In the same species of animal, when differences of volume correspond to different varieties, as in the dog, the quantity of liver per kilogram of animal is higher as the animal is smaller. This proportion also varies with the nature of the food.—On the variations of phosphorus in animal tissue, by M. A. L. Percival.—Physiological researches on the effects of cervical sympathicectomy, by MM. Moussu and Charrin.—Muscular hæmoglobinuria, by MM. Jean Camus and P. Pagniez.—On the formation of the *anticorps* in the serum of vaccinated animals, by MM. A. Calmette and E. Breton.

PROF. GIGLIOLI'S COLLECTION ILLUSTRATING THE STONE AGE.

Materiali per lo Studio della "Età della Pietra" dai tempi preistorici all' epoca attuale. Origine e sviluppo della mia collezione. By Enrico Hillyer Giglioli. Pp. 248. (Florence: S. Landi, 1901.)

THE publication of a detailed description of the private collection formed by Prof. Enrico Giglioli is a welcome and important event, and one to which students of archæology and ethnology have long looked forward. Even to those who have not enjoyed the privilege of visiting Prof. Giglioli at home and seeing his treasures, it has been known by many indications that a scientific collection of no ordinary calibre was being brought together by the energetic professor. The actual wealth of material accumulated, as revealed by the present publication, is, however, somewhat startling, and one can but admire the perseverance and success with which he has pursued his hobby. One must refer to his studies and investigations in the fields of archæology and ethnology as a *hobby*, since Prof. Giglioli is a zoologist by profession, his official time being occupied in his professorial duties and his work as director of the important Zoological Museum in Florence. His private collection and the studies connected with it are the results of his leisure time labours, and one may readily infer that he has never indulged in that doubtful luxury "an idle moment." "Chi vive lavorando non ha mai tempo abbastanza," he laments, but he has utilised his available time to the utmost, by methodically devoting his daytime to zoology and his evenings to his collection. In the formation of his very extensive collection, he has kept always in view the definite object with which in 1883 he commenced to collect. His primary aim has been throughout to elucidate so far as possible the "Age of Stone" by means of comparative study; and to this end it has been his endeavour to secure as complete a collection as possible of objects illustrating, not only the life and arts of prehistoric Stone-age man in all countries, but also the conditions of culture of recent savage and barbaric races, whose developmental progress has from various causes been arrested or retarded, and who, therefore, may be regarded as *survivals* from various early stages in the general development of the human race. The bringing together of archæological and ethnological material into close association for purposes of scientific study, to the end that the specimens in the one class may serve to elucidate those in the other, has now long been recognised as of the greatest scientific value. Colonel Lane Fox and Mr. Blackmore were early pioneers in this field of inquiry, and the lessons which they taught still hold good and are increasingly appreciated.

Prof. Giglioli's publication is primarily a descriptive guide to his private collection, drawn up methodically under geographical headings and subheadings. The work is, however, more than a mere detailed catalogue, as its scientific value is enhanced by a running commentary of considerable interest to the archæological and ethnological student. While approving the general form and scope of the work, one cannot but note one serious defect, tending greatly to reduce the utility of this otherwise valuable guide. There is no index to contents. A work of this nature should certainly be furnished with a good index; it should, in fact, be doubly indexed, on the one hand under geographical, and on the other under subject headings. The labour of producing the index would be well repaid by the appreciation with which this important feature would be received, and we may still hope that the author will issue an index in full which may be bound up with the work. There are several very fair illustrations in the text. It would be impossible within the limits of a short notice to give an idea of the richness of this collection. Many of the rarer objects are represented by good series, as, for instance, the New Zealand *hei tiki*, of which there are ten of nephrite, one, perhaps unique, of diorite, and others of bone. There are no fewer than 177 *toki* or stone adzes from the same region. Witness also the remarkable series of hafted stone axes from South America and the thirty-two ceremonial adzes with elaborately carved handles from Mangaia. Among the less rare forms, the numbers run high, and there are no less than 325 stone adzes and chisels from the New Guinea region. Both the art of war and the arts and industries of peace are well illustrated. Many of the uncommon localities which are included in the very comprehensive list of carefully localised specimens are but very rarely represented in even the more important museums, a fact which would of itself place this collection in the front rank. In his descriptions, Prof. Giglioli has given brief notes upon the races and tribes dealt with their geographical position, &c. Wherever possible, he has given the native names of the objects, and details as to manufacture and other points of interest are touched upon, rendering the work (especially if indexed) a valuable book of reference to ethnologists and collectors.

One may readily endorse the hopes expressed by the maker of this remarkable collection that it may eventually find a permanent home in a public museum and be preserved in its entirety. It would be almost a crime to allow the dispersal of a collection so complete and so systematically and laboriously brought together.

EXPLOSION MOTORS.

Les Moteurs à Explosion. By G. Moreau. Pp. xii + 444. (Paris: Libraire Polytechnique, Ch. Béranger, 1900.)

Théorie des Moteurs à Gas. By G. Moreau. Pp. 224. (Paris: Ch. Béranger, 1902.)

THE extraordinary developments which have attended the application of explosion engines to motor vehicles, and the rapidity with which the constructors of these light and powerful engines have carried their designs well within measure of practical perfection, forms one of the most noteworthy achievements of modern engineering.

The time has, however, arrived when practice must be tempered with a sound knowledge of theory, in order that further advances along the existing lines of construction may be achieved.

With this object in view, M. Moreau has compiled two

H

volumes in which the theory of explosion motors and the nature of the combustibles used therein are detailed in a thoroughly clear and systematic manner. The two volumes cover to a certain extent identical ground, but in the earlier work the subject is treated in its widest sense and the mechanical features of the motor vehicle as a whole are freely investigated; while in the later work the author confines himself exclusively to the engine, and here brings the theory of the subject well into line with the latest developments in practice, at the same time indicating the directions in which further improvements may be arrived at.

In the earlier work, the opening chapter is devoted to purely theoretical considerations of motors operating with perfect gases, and the laws regulating the behaviour of such gases under varying conditions of pressure and temperature. The imperfections of the gases actually available in practice are then considered, and the working conditions of the various cycles which may be employed are investigated. A chapter is devoted to the question of the specific heats of gases under various conditions, the question of the rate of the explosion relative to piston velocity, and the losses in actual engines due to throttling at the inlet and exhaust, to the cooling of the cylinder walls and to heat rejected on exhaust; representative diagrams are given and the total losses discussed.

Three chapters are then devoted to questions connected with the mechanical design of engines and motor vehicles, such points as the movements of the piston, connecting rod and crank-pin, valve movements, frictional losses and the strength of materials being fully discussed. All the chief organs of the transmission gear and special items such as axles, wheels, brakes, pneumatic tyres, carburettors and ignition apparatus are dealt with in detail, the author carrying his investigations in this portion of the work far beyond the limits indicated by its title. The nature and properties of the various combustibles which are available for explosion motors are next fully considered, the author remarking with much truth on the extraordinary ignorance amongst constructors on this particular branch of the subject. The work concludes with a comparison of trials of motors and automobiles, and considerations relative to the most suitable cycle to employ, the author advocating a six-stroke cycle —namely, admission, compression, expansion, recompression, explosion, exhaust—the advantages gained being a better mixture, re-heating of the charge after it has entered the cylinder, and abstraction of heat from the walls, which would diminish the loss to the cooling water.

In the more recent volume, which is based on a series of lectures delivered before the Automobile Club of France, the functions of every type of explosion engine which may be employed on a motor vehicle are investigated in a systematic manner. All the most important points in the design of engines, such as the volume of the compression chamber relative to the total cylinder volume, the influence of the walls, of the periods of admission and exhaust, and of the propagation of the explosion are carefully considered.

The concluding chapter, which forms nearly one-third of the volume, is devoted to the nature of the combustibles which may be employed, to the best conditions for the running of an engine and to investigations of the inertia of the reciprocating parts.

The subject in both volumes is handled in the clearest possible manner, and although higher mathematics is freely employed in every investigation, each step is so carefully traced that the author may be followed to his conclusions by all who possess a practical knowledge of the subject of explosion engines.

C. R. D'ESTERRE.

MARIGNAC AND HIS WORK.

Œuvres complètes de Jean-Charles Galissard de Marignac. By E. Ador. Tome i., 1840–1860. Pp. lv + 701. (Genève: Eggimann, n.d.)

THIS edition of the works of Marignac is prefaced by a biographical sketch by his son-in-law, Prof. Ador. From this sketch, we learn that Marignac, a native of Geneva, came of a scientific stock; at the house of his uncle, Le Royer, he early made the acquaintance of distinguished men, of whom there has been no lack in his native town. Prévost, De Candolle and Dumas were frequent guests in Le Royer's pharmacy, and from them young Marignac imbibed that single-hearted devotion to science which so strongly characterised him. He began his career, not as a chemist, but as an engineer; he was a pupil of the École Polytechnique, and later of the École des Mines, at Paris. His talents had so strongly impressed the French authorities, however, that long after he had ceased to be connected with France and had accepted his chair at Geneva, the French Government expressly granted to him the right to keep the title "Ingénieur des Mines," in spite of his having ceased to be a French subject.

In 1840, when twenty-three years of age, he came under the magnetic attraction of Liebig and passed a semester at Giessen; and it bears high testimony to Marignac's genius to find that after that short probation he was offered, and accepted, the much-coveted post of chemist to the porcelain factory at Sèvres. He occupied the position only six months, and on receiving a call to fill the chair of chemistry in the Academy of Geneva (for the University had not at that time been created), he at once accepted, finding his life work in an academic career. As professor there, he lived and died, although in 1878 he withdrew from active teaching. Never robust, he succumbed gradually to an insidious disease, and he died in 1894, after a long and tedious illness, borne with the utmost fortitude. His lectures were models of method and clearness—indeed, these were the characteristic features of all his work—and his modesty, patience and perfect conscientiousness gained for him the esteem of the whole scientific world, testified by the numerous honours which fell to his lot.

His only researches in the domain of organic chemistry, no doubt suggested while in Liebig's laboratory, dealt with phthalic acid and the action of nitric acid on naphthalene. It was at Geneva that he began the series of investigations on atomic weights which have rendered his name famous. The inducement was to test Prout's law; and the ratio between the atomic weights of chlorine, potassium and silver first occupied his attention. His attempts to prepare pure material for experiment

led him to undertake numerous subsidiary investigations, some dealing with isomorphism, some with the diffusion and specific heats of salt-solutions. His researches on the double salts of fluorine and potassium with silicon, titanium, tungsten, zirconium, niobium and tantalum, and on the rare earths were all part of his scheme to ascertain the true relations between the atomic weights of the elements. During the forty-five years of his scientific activity, he determined the equivalents of no fewer than twenty-eight elements. Besides these labours, he added to our knowledge of ozone and conducted experiments with Foucault's pendulum.

M. Ador's sketch of Marignac gives an interesting summary of this work, adding also a sketch of the part which he took in developing the modern aspect of chemistry, in adopting the now familiar means of deducing atomic weights from the equivalents determined by analysis.

The present volume is the first of a series of reprints of Marignac's original papers, most of which were published in the "Archives de la Société d'Histoire Naturelle de Genève." The typography and arrangement leave nothing to be desired, and M. Ador has conferred a benefit on his fellow-workers by the labour of love which he has so successfully carried out, and has paid the best possible tribute to the revered memory of his old master. W. R.

A MANUAL OF PHYSICAL GEOGRAPHY.

An Introduction to Physical Geography. By Grove Karl Gilbert and Albert Perry Brigham. Pp. xvi + 380. (London: Hirschfeld Brothers, Ltd., 1902.) Price 5*s.* net.

IT might reasonably have been supposed that there was no field in the United States for a new concise manual on physical geography. Yet the cooperation of one of the most original observers of geological phenomena with the practical teacher of geology in Colgate University has given us a book that we should be very sorry to lay aside. It has, like many of its rivals, been brought unmodified into the English market, where it will appeal to teachers rather than to junior scholars. It would be, indeed, no more suited, with its wealth of American illustration, to European classes than Huxley's description of the Thames Valley would be to dwellers on the Mississippi or the Hudson. But in the continent of North America this little book should take a foremost place. The abundant photographic illustrations are excellent and well chosen. They are not reduced, as in some small text-books, to blurred patches which suggest no natural landscape. The process-blocks seem to us to vary slightly in grain, whereby some of the smaller ones have been brought to a rare degree of delicacy; the sand-ripples on the dunes in Fig. 83 will serve as an example. To name two other suggestive pictures, the contrast of delta and cliff in Fig. 37, and the geognostic details of the "creeping" rock-surface in Fig. 59, are especially well presented.

The style of the text forces the meaning of the illustrations on the reader. The same firmness appears in Mr. Gilbert's "Geology of the Henry Mountains" and "Lake Bonneville," but the effect is there modified by a far more classical terminology. Whether or no joint authorship is responsible for the diction in the present book, the result may be commended as a consistent work of art. These short, direct, eminently English sentences are not easy to write, but are delightful to read and are perfect for their purpose.

The current system of importing American books intact under the name of a London publisher leaves us, even in this case, with such spellings as "oxid" and "sulfur," and such antique words as "sled." While Prof. Brigham writes "bowlder," the joint authors, however, give us our own form, "boulder." "Glen" and "dale" may be, as stated on p. 28, "somewhat poetic" in America, where "gulch" is common, but they are fortunately familiar to every hillman in our islands. Yet these are trifles in a book that appeals to us as much by its style as by its subject.

The authors conceive geography (p. 13) as a comprehensive knowledge of the earth, and their book as a first book of science, similar, we take it, to Huxley's "Physiography." They attract attention to the features seen in any walk across the country, and correlate these with the striking phenomena of high mountain regions, volcanoes, and so forth. On p. 209 the recent eruptions in Martinique are judiciously introduced.

There is little experimental method in the book; the rain-gauge, for instance, is mentioned, without any statement of how a reading can be made in actual practice; the chemical characters of limestone are given, without a hint of how the material may be interestingly dealt with by the pupil. The teacher will, however, supplement the book in these matters, and its clearness of description cannot fail to give him new conceptions. What can be better, for instance, than the remark (p. 279) that "the ocean may be likened to a film of liquid clinging to the outside of a spoon"? We should like to quote some of the more vivid passages, such as the contrast between life in the Alps and in the Rocky Mountains on pp. 191–2. We do not agree with the authors in their discussion of passes in the Pyrenees and Alps, or as to "the somber skies of Germany" (p. 195), when Baden and Bavaria are referred to; but we should probably be far more at fault were we to illustrate—or, as the authors say, "illuminate"—a European text-book by remarks on Georgia or Colorado. GRENVILLE A. J. COLE.

A PICTORIAL ARITHMETIC.

The Modern Arithmetic. Primary and Elementary Grades. By Archibald Murray, A.B. (Harvard). Woodward Series. Pp. 308. (St. Louis, U.S.A.: Woodward and Tiernan Printing Co.)

THIS is a book for the use of a teacher of very young pupils. It is divided into three parts. Part i. (82 pages) is concerned with "number exercises," and consists of thirty-eight lessons, each one of which we may suppose to occupy the child for one day. Each of these lessons consists of a series of questions or directions given to the pupil, such as "hold up seven fingers," "find, by using splints, the half of ten units," &c. A marked feature of this part of the book is the beautiful series of coloured pictures of roses, apples, grapes, strawberries, oranges, finches, redbirds and other interesting

objects which it contains, while the interest and curiosity of the young pupil are further secured by a good drawing of a spider and his web, as well as by an excellent picture of a pair of boots.

This part of the book deals, then, as the author says, solely with ideas of comparison, measurement and counting. The extent to which we get in part i. may be inferred from the last two questions or problems in it :—

"A book cost 3 dimes, a pencil 3 cents, and a blank book 3 nickels. How many cents did all three cost? Count from 1 to 30; from 5 to 100 by fives. Count as high as you can by hundreds."

Part ii. treats of the elementary operations—addition, subtraction, multiplication, division—and the meaning of fractions (halves, thirds, quarters, &c.) is gradually unfolded during these operations. The pictorial method is continued in this part, but the pictures are of the geometrical kinds that we get by cutting out and folding paper, so that the measurement of simple areas and the nature of an angle are explained to the little learner. Thus, one of the things here learnt by folding is that the sum of the angles of every triangle is two right angles. Near the end of this part, the nature of a decimal is explained, and the extent to which the pupil has progressed may be seen by the following, taken from the last lesson in part ii. :—

"At the rate of 56 miles per hour, how far will a train travel in 5·6 hours? A bookseller paid \$$9\frac{3}{4}$ for books. How many did he buy if each cost \$$\frac{3}{8}$?"

Part iii. treats of "elementary operations classified," that is, the operations of part ii. are treated more in detail and the philosophy of the subject is expounded. Near the end, the nature of ratio and proportion is explained, instruments, such as a two-foot rule, being employed. Among the terminal problems in this part are the following :—

"Express 9 cu. yd. as a decimal of a cord" (from which we conclude that the author does not anticipate an early introduction of a thorough-going metric system into America); "what is the sum of $\frac{2}{3}$, $\frac{3}{5}$, $\frac{5}{7}$ and $\frac{7}{9}$? The rate of taxation of a city is $1\frac{1}{2}$%. What tax must a citizen pay whose property is assessed at \$4500?"

There are no answers supplied to any of the questions (except in two or three instances) throughout the book; it is, as we have said, a guide to the teacher; the young pupils for whose instruction it is intended are not yet *students*.

Of course, the American coinage, with which the questions deal, would require alterations to render the book suitable to English use; but there is no doubt that the author has very skilfully conceived the nature of an effective process of teaching young children, and we think that the exact following of his course and method would prove to be productive of excellent results.

OUR BOOK SHELF.

The Trees, Shrubs and Woody Climbers of the Bombay Presidency. By W. A. Talbot, F.L.S. Second Edition. Pp. xxv + 385. (Bombay, 1902.)

WHEN Sir Joseph Hooker's "Flora of British India," now completed, was undertaken, one of its main objects was stated to be to furnish a basis on which local floras could be constructed. India is so vast, its climatic features are so varied, the economic requirements of its several provinces so diverse, that a general work like that of Hooker needs to be supplemented by local floras in which the special requirements of particular districts can be fulfilled. There is gratifying evidence to show that these requirements are in course of being supplied. There is, for instance, the "Forest Flora of the North-West," by Sir Dietrich Brandis; Sir George King is engaged on the "Flora of the Malay Peninsula"; the "Flora of Ceylon" was completed by the late Dr. Trimen; and General Collett's book on the plants of the Simla district has just been published. We might cite many similar works from the pens of Prain, Clarke, Duthie, Watt, Kurz and others, but enough has been said to show that Sir Joseph Hooker's aim is in process of fulfilment, and that the splendid botanical heritage handed down to us by Roxburgh, Wallich, Wight, Griffith and others is in no danger of being squandered, but is being utilised and extended by the labours of the present race of botanists. When we bring to mind the fact that instruction in botany, at any rate in systematic botany, no longer forms part of the curriculum in the education of medical students, and that complaints have been made as to the lack of interest felt in the subject by the majority of forest officers, this evidence of substantial progress may at least be adduced as a set-off.

The work before us is another instance of the same kind. In form it is modelled upon Hooker's "Flora," in substance it contains a "fairly correct" list of the indigenous ligneous vegetation of the Presidency, together with additional matter relating to distribution, bark, woods and economic products, along with a large number of vernacular names.

The book is in its second edition, and hopes are thrown out that the "next edition" will expand into a handy Bombay forest flora. Actual use in the field or forest, or even in the herbarium, is needed to enable the reviewer to form a complete estimate of the value of such a work. It must suffice to say that the author's method is good, and that it bears the impress of care and accuracy in its production.

La Géologie générale. By Stanislas Meunier, Professeur de Géologie au Muséum d'Histoire Naturelle. Pp. vi + 336; 42 woodcuts. (Paris: Alcan, 1903.) Price 6 francs.

IN this volume, Prof. Stanislas Meunier undertakes, for the International Scientific Library, a presentation of those branches of geological science not already dealt with in his "Experimental Geology" and his "Comparative Geology," published in the same series.

In the introduction to the book, the author defines the ideas which have successively dominated geological theory during the nineteenth century as (1) the cataclysmal views of Cuvier; (2) the uniformitarianism of Lyell; (3) the "actualism" of Constant Prévost; and (4) the "activism," which he regards as the distinctive feature of modern geological thought.

In conformity with this latter point of view, the author then proceeds to discuss the three great causes of change in the earth's crust, namely, the central heat of the globe, the effects of pressure and the influence of the sun's heat. Pursuing this deductive, rather than inductive, mode of treating his subject, the questions next considered are the flexible earth's crust, volcanoes, the action of subterranean and superficial waters, the sea, glaciers, the atmosphere, and vital action. In dealing with each of these subjects, the originality of the author is everywhere manifest, the examples and illustrations chosen being, for the most part, new, and often of a very striking character.

In the second part of the work, which is entitled "Comparative Physiology of Successive Geological Epochs," the effect of the several agencies enumerated

during past geological periods is traced, and here we have to notice the same freedom from the stereotyped methods and matter of text-books of geology which we have remarked upon in the earlier portions of the work. Subjects like the cause of the formation of concretionary structures in rocks are treated at considerable length and with much skill, though, it must be confessed, with considerable inequality. On the other hand, many important questions which do not happen to have been made the subject of special research by the author are treated in a superficial manner or altogether passed over, there being little obvious connection between the space devoted to various divisions of the subject and their relative importance.

As a work designed to attract the attention of a general reader and to stimulate the thought of more advanced students, the work is excellent. But it is rather as a supplement to other books on the subject than as an independent treatise that its value is most apparent, for it is wanting in many of those features which are necessary in a work which is designed to give a presentation of the present state of geological knowledge. It is unfortunate that the book is not provided with an index.

The Student's Handbook to the University and Colleges of Cambridge. First Edition, Corrected to June 30, 1902. Pp. 468. (Cambridge: University Press, 1902.) Price 3*s.* net.

IN this volume, the editor has brought together in a concise form all the more interesting facts and methods of procedure which every student should desire to know as he proceeds to the University of Cambridge as an undergraduate. There are twenty-three chapters in all, and each is devoted to special items.

After a short and condensed account of the history of each college, with a list of the officials at present in residence, the reader is made acquainted with the conditions of admission to any particular college, the period of residence, discipline, and an excellent survey of the average expenditure necessary.

The next four chapters are devoted to the details of the conditions and value of the entrance scholarships, exhibitions and sizarships, and the various University and college scholarships and prizes, concluding with a general account of the objects for which the several institutions of the University are utilised.

The handbook then gives useful information on the work of teaching as divided between the University and the different colleges, and then proceeds to bring together all the necessary information for those who are about to qualify for the previous, ordinary B.A. degree, and honours examinations.

After two brief chapters on advanced study and research and examinations for medical students, detailed information is given on the subjects of the B.A. and superior degrees, diplomas and fellowships, followed by useful chapters for candidates for Holy Orders, for the Civil Service and Army, and for teachers.

The final chapters show the facilities for the education of women in the University, an account of the more important outside examinations conducted by the University, concluding with a description of the object and work of the scholastic agency and the Appointments Board.

Bacteriological Technique and Special Bacteriology. By Thomas Bowhill, F.R.C.V.S. Second Edition. Pp. xvi + 324. (Edinburgh: Oliver and Boyd, 1902.) Price 21*s.* net.

As might have been anticipated, a second edition of Prof. Bowhill's book has been rendered necessary by the rapid sale of the first edition.

The book is divided into seven parts, as follows:—Part i., principles of bacteriological technique; part ii., the preparation of nutrient media; part iii., special bacteriology; part iv., the Hyphomycetes; part v., the Blastomycetes; part vi., the Protozoa; part vii., diseases due to undetermined infective agents. The illustrations number 136 and they are all of the highest class. In particular, the photomicrographs, executed by the author and reproduced by the collotype process, are admirable.

The author has the advantage of being, not only a bacteriologist of high repute, but also an acknowledged veterinary expert. It is not surprising, therefore, to find that the diseases of microbial origin, which affect the lower animals as well as human beings, are dealt with in a conspicuously able fashion.

The descriptions of swine fever, swine plague, swine erysipelas, pleuro-pneumonia, contagiosa bovis, broncho-pneumonia bovis, grouse disease, diphtheria and glanders are excellent.

The author has added much new matter to the text, and the book is thoroughly up to date.

Part vii., dealing with diseases due to infective agents of undetermined character, is a specially useful article. As regards rinderpest, the author gives a graphic account of the methods adopted during the recent outbreak of the disease in South Africa. The methods were as follows:—(1) Koch's original bile method; (2) glycerinated bile method (Edington); (3) serum method of Turner and Kolle; (4) defibrinated blood method. Lucid descriptions are given of the best way of preparing the serum, bile and defibrinated blood.

The methods of examining air, water, soil, unsound meat and ice cream are insufficiently discussed, and the bacteriological examination of sewage is apparently not considered at all.

In conclusion, it may be said that no student in veterinary, medical and sanitary science should be without a copy of this excellent manual. That the book will enhance the enviable reputation of the author is beyond question.

Practical Electricity. By J. Hope Belcher. Pp. xi + 165. (London: Allman and Son, Ltd., 1902.) Price 2*s.* 6*d.*

THIS book is intended to be an elementary manual for a laboratory course in practical electricity. It contains instructions for carrying out a number of experiments designed to illustrate the principles of magnetism and electricity. The course is largely modelled on that given by Prof. Ayrton at the City and Guilds Institute. The experiments are well chosen, and the description and instructions seem to us adequate. The student is shown how to tabulate and set out his results, and some useful hints are given to teachers of elementary science as to the conduct of a laboratory class. We notice in one of the experiments the old fallacy of "proving" Ohm's law by a method in which P.D.'s are measured with an electromagnetic voltmeter; it is remarkable how hard this fallacy is to kill. Apart from this and a few minor blemishes, Mr. Belcher's book is a useful little manual.

M. S.

Acht Vorträge über physikalische Chemie. Von J. H. van 't Hoff. Pp. 81. (Braunschweig: Vieweg und Sohn, 1902.) Price 2 Mk. 50 Pf.

PROF. VAN 'T HOFF delivered these lectures in June, 1901, on the invitation of the University of Chicago. As they were intended for a mixed audience, they have a more or less popular character, but in places they would be difficult for anyone lacking special knowledge to follow, without the personal influence of the lecturer. Two lectures each are devoted to the influence exerted by physical chemistry on pure chemistry, technical chemistry, physiology and geology. The treatment is necessarily meagre, but many interesting subjects are touched upon, and to students of science these lectures must prove stimulating and suggestive to a degree.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Secular Changes of Climate.

FOR some time past it has been generally believed that the climate of Central Asia was once less arid than at present, but we now know, as Dr. Sven Hedin explained to the Royal Geographical Society on December 8 (p. 134), that important changes have taken place since the Christian era began. He found in the Lob Nor region forests with the trees long dead, traces of a road, ruined villages, coins, manuscripts and other relics which proved the northern shore of the old salt lake (now dry) to have been cultivated and occupied, down to about sixteen centuries ago, by a fairly civilised people. This, I think, implies a rainfall, less inappreciable than the present one, during the earlier centuries of that era, and the change, as he found dead forests, cannot be attributed (as in parts of southern Europe and Syria) to reckless destruction by the hand of man. But, besides this, Sir Norman and Dr. W. J. S. Lockyer have recently proved (in a communication to the Royal Society) a very remarkable correspondence to exist between the distribution of the periodic rains in India, Mauritius and elsewhere and the amount of solar activity, and they have, within the last few days, drawn the attention of the same Society to the fact that zones of abnormally high and low mean barometric pressure exist on opposite sides of the earth and oscillate from the one position to the other in accordance with the periodic small variations of solar activity. Dr. Sven Hedin's discovery apparently indicates a change secular rather than periodic, but may not both operate independently, as in the case of changes due to variations of eccentricity in the earth's orbit and to precession of the axis of rotation? The authors of those papers admit the existence of disturbing causes, some of which may be local, but not necessarily all. Is it, then, possible that these discoveries may afford a clue to the solution of two great geological puzzles—the abnormal temperatures of the Pleistocene and of early Tertiary times? In regard to the former, many now believe that the climate of North Central Europe when the loess was deposited more nearly resembled that of the Caspian steppes, and all maintain that in the Glacial epoch the mean temperature of the whole continent was much below what it is now. How much this was, at the time of greatest cold, is not easily estimated, but a few years ago I attempted a rough approximation. This will be found in a volume of the Contemporary Science Series called "Ice Work" (part iii. chap. i.), and the results (for Europe) are as follows:—Supposing the British Isles to be at their present level (in order to avoid the controversy as to the origin of Boulder-clays and Glacial gravels), the mean temperature of these islands at the present Ordnance Datum would have to be lowered by about 20° F. The same would probably hold good of Scandinavia—at any rate, that would suffice to make either country much more closely resemble a corresponding part of Greenland. In the more central parts of Europe, the problem is rather easier, for here we are undoubtedly dealing with "land-ice." A fall of 18° in the mean temperature would suffice for the Alps; perhaps rather less, 15 or 16°, for the Pyrenees, the Sierras Guadarrama and Nevada, possibly also for the breccia-producing age on the Rock of Gibraltar. A reduction of 18° at most, and more probably about 16° or 15°, would bring back small glaciers to Auvergne, the Schwarzwald, Vosges, Apennines, Corsican mountains, the Caucasus and even the Atlas. I may add that a reduction of 15° appears sufficient to form a great ice-sheet in North America, and that in the southern hemisphere and at Mount Kenya in Africa distinctly smaller change suffices. All these estimates assume the present levels maintained; they may be corrected at the rate of 1° for each 300 feet of elevation or depression. But geologists too often forget that the anomaly of early Tertiary heat is not less difficult to explain than that of Pleistocene cold, for in later Eocene ages the mean temperature of southern England can hardly have been less than 20° above that which it now enjoys. The explanations which have been offered for the Glacial epoch —a different arrangement of sea and land, variations in eccentricity, precessional movements (none of which, in my opinion, are more than partially successful)—cannot be applied to the latter case, so that we seem compelled to seek for some other cause. Variations in solar heat have been already suggested, but hitherto this hypothesis has seemed too much a *Deus ex machinâ*. But as Dr. Sven Hedin's discoveries show that important alterations in climate have been in progress during the last fifteen or sixteen centuries, and Sir Norman Lockyer's researches indicate that comparatively small changes in solar activity produce rather important meteorological effects upon the earth, geologists qualified for the investigation may find it not unprofitable to follow up the clue. T. G. BONNEY.

The Government Grant for Scientific Research.

NOW that the annual advertisement of the Government grant is once more appearing, I should like to call attention to the long interval that elapses between the date appointed for the reception of applications for, and that of making known the distribution of, the grants. The former is fixed for January 31, the latter is some time in May, a period of more than three months. This seems to me to detract somewhat from the value of the grants, for, in certain instances at least, the conditions may have quite altered in so long a time and the possibility of making a particular research have passed away.

King's College, December 8. R. T. HEWLETT.

The Unconscious Mind.

IN a recent review (November 20) of my book on the "Force of Mind," "W. McD." remarks, "The book is vitiated throughout by the insistence upon the part supposed to be played by the unconscious mind."

But a closer attention to the argument would have revealed the fact that, while no stickler for a word and still less an advocate for two minds, the author is compelled to give some name for mental processes unaccompanied by consciousness.

The position of the man who denies any mental processes at all, as distinguished from mechanical, is logical; but the position of the man who distinguishes mental processes (that is, processes which a machine cannot conduct apart from mind) from mechanical, and at the same time will only recognise as mental those accompanied by consciousness, is illogical. The self-same mental process at one time may be conducted in consciousness and at another outside it, and he is therefore on the horns of this painful dilemma. He must either at one time call the process mental and at the other mechanical or "nervous," or he must extend the word "consciousness" so as to include the unconscious. To a psychologist, the consequences of such a theory are deplorable and are described in scathing terms by Prof. James [1] when he depicts the present state of this conservative science; while with a medical man it compels him logically to regard cases of neuromimesis as malingering or fraud because he sees the disease has mental characteristics, and yet cannot, according to the old psychological shibboleth, recognise as mind the unconscious psychic agent. I may say in conclusion that the need for this extension of mind has been felt by none more keenly than by the very psychologists who have refused it. The student of this subject has only to turn to Prof. C. T. Ladd's "Philosophy of Mind," p. 395, and compare it with p. 393; or to Prof. Sully's "Illusions," pp. 266 and 335, to see the existence of unconscious mental actions both asserted and denied in the same book.

These passages and others will all be found in my work [2] on the subject. A. T. SCHOFIELD.

6 Harley Street, W., December 15.

DR. SCHOFIELD objects to my strictures on his extensive application of "the unconscious" as an explanatory principle that solves (for him) all problems of the relations of body and spirit. And he persists in confusing the question of the validity of "the unconscious" with the question of the propriety of so extending the use of the terms "mind" and "mental" as to make them applicable to brain activities that do not involve affections of consciousness. This extended use of the words I myself, following Dr. Bastian, have urged and adopted, but to do this is not to commit oneself to the hypothesis of "the unconscious mind." Dr. Schofield's use of this phrase implies the assumption of a factor in mental life that is neither neural process nor conscious process, but an utterly unknown, unknowable and mysterious third agent, more or less intervening between the two

[1] Prof. W. James, "Psychology," p. 468.

[2] Dr. Schofield, "The Unconscious Mind," 2nd edition. (Hodder and Stoughton.)

known processes. This I hold to be a radically vicious hypothesis, not merely because it is unverifiable (for, in spite of the dictum of J. S. Mill, that appears to be an insufficient ground for condemnation), but (1) because it invokes an agency of an absolutely unknown order, (2) because it is not necessary and does not help us to give a consistent description of the facts, (3) chiefly because it serves merely as a cloak disguising our ignorance and must tend to make those who adopt it content to remain ignorant. Dr. Schofield's position seems to be based solely on the following argument:—

The human organism exhibits activities that cannot be shown to be accompanied by corresponding states or processes of consciousness, but which nevertheless display so great a complexity and nicety of adjustment of means to ends that we cannot suppose them to be carried out by the agency of neural processes only; therefore we must assume an agent that plays a part similar to that which we assign to consciousness, but differing from it merely in not being consciousness. But when many of our leading thinkers accept the view so clearly enunciated by Huxley in his essay on "Animal Automatism," the view, namely, that all human activities are carried out by the agency of neural processes without the causal intervention of any other factor, consciousness being an epiphenomenon merely, why should Dr. Schofield believe himself competent to draw a line at any particular degree of complexity of behaviour, saying "So much can the unaided neural processes accomplish, but no more."

W. McD.

THE UNIVERSITY OF LIVERPOOL.

IN 1879, Dr. Lightfoot, speaking at a prize-giving in Liverpool, described as seen in a dream its future University College. The speech had no small influence in securing the foundation of the College, and twenty-three years have done much to realise the dream.

The progress of University College has been most striking; it started in 1881 with seven professorships and three lectureships. Now there are twenty-one professorships each endowed with the sum of 10,000*l.* and one temporarily endowed. The total number of professors, lecturers and assistants is seventy-two, and the value of the endowment about 226,000*l.*

Practically all of this has been given by citizens of Liverpool, much in single sums of 10,000*l.*, for the founders, inspired by Mr. Rathbone, were wise men, and realised that they were providing for a large need and must do it on a large scale.

The value of the College site and buildings already erected is about 280,000*l.*, while 50,000*l.* from the fund recently raised is to be spent immediately in further buildings. For scholarships, prizes, the maintenance of laboratories and of the Day Training College, about 60,000*l.* has been invested; a capital sum of more than 600,000*l.*, contributed in twenty-three years by Liverpool benefactors for the advancement of learning and for the education of their townsfolk.

Besides this, large sums are given voluntarily each year for annual expenditure. The city shows its interest in a practical manner by the grant it makes towards certain of the technical classes, while the fees received from students last year reached 13,000*l.* These results, though they may seem small compared with some of those achieved through individual generosity in America, are splendid. The Bishop's dream is nearly realised.

Now the men who have done this come forward and say that it is necessary for the future success of their work that the union which exists between the three colleges of the Victoria University should be dissolved, and that Liverpool should have its own University. Can anyone gainsay their right to speak or urge that they are not the best judges of their case?

They speak with no uncertain voice. The Education Bill transfers to the City Council the control of education in the city, and the Council is of opinion that a University of Liverpool is necessary as the keystone of the arch it intends to build; it has already received power to raise a rate for university education if a Charter is granted to University College, and it intends to do it. It is inconceivable that that Charter should be refused, that the Government, which has indicated its wise desire to leave freedom wherever possible for the development of education according to local needs, should refuse the request of one of the greatest of the local authorities of the country, the Corporation of Liverpool, to complete its work by establishing a "great university for a great city." These were the words used by Mr. R. B. Haldane at a city dinner in Liverpool some four years since; it was clear from their reception then that the ideal he put forward appealed strongly to the representative gathering which he addressed, and in the joint petition of the City and University College for a Charter which is now before the Privy Council we have the outcome of his words.

The case is one which carries conviction as it is read. The grant, it is urged, would greatly stimulate the development and increase the influence of University College and other institutions for the promotion of higher education in the city; it would bring higher education into closer connection with the professional and commercial life of the city; it would provide a true university education for many who cannot leave home to obtain it—the promoters urge with success the distinction between education in a university college, a part of a federal university, and that in a university—it would stimulate research by multiplying in the proper places the centres at which this can be carried on, and, having regard to the inadequate provision of the higher forms of education in England relatively to foreign nations, would be for the benefit of the nation as a whole.

Each of these claims is substantiated by solid facts.

The success of the movement will mean the dissolution of the Victoria University in its present form.

To this, Owens College, the predominant partner in the federal University, has given a ready consent; the two great cities of south-west Lancashire are at one in the belief that each may well be the centre of an independent university, and the case for Owens College is in many ways stronger than that for Liverpool. Yorkshire College, on the other hand, wishes to retain the present system. The financial position of Yorkshire College is much weaker than that of her sister colleges; Mr. Lupton at Leeds in January last said, when speaking of the number of its students, "It will compare favourably and creditably with the other two colleges of the University, but in its material assets it is ludicrously wanting. In the capital of the College, the assets are between 250,000*l.* and 300,000*l.*, but the money has been spent on buildings, apparatus, &c. Of invested capital, we have not quite 39,000*l.*, the income of which goes to the annual expenditure of the College."

At present, then, Yorkshire College is less fitted than the others to become a university, hence in part its dislike at being left alone. But Yorkshiremen are quite able, as was stated by the Principal of the College and the Bishop of Ripon at the same meeting, to create a university of their own if the need for it arises, and it will be found in Leeds no less than in Liverpool that a great university is a great power for good and for advancement.

To Liverpool and Manchester, the failure of the petition would be disastrous; it would curb enthusiasm, it would check the flow of benefactions for education, it would discourage men whose whole heart is in the great work they have set themselves to do, to build in each of these two cities a university which they feel is needed for the highest training of men and women in whose hands the future rests; it would compel two responsible bodies who have each decided that it can best perform its allotted duties separately to endeavour to struggle on in a union which they feel is hopeless.

All this is clear to anyone reading the case presented, so clear that of the issue there can surely be no doubt.

THE MINNESOTA SEASIDE STATION.

AMONG newer American establishments for the study of marine biology, the Minnesota Seaside Station has awakened considerable interest. It is upon British soil, being situated about sixty miles north-west of Victoria, British Columbia, just at the entrance of the Straits of Fuca. The site was chosen after a careful reconnaissance of the Pacific coast, both Canadian and American, and presents some remarkable advantages. So far as accessibility is concerned, it may be reached from Seattle, Port Townsend or Victoria, and commands, not only the outer waters of the ocean, but the region of Puget Sound as well.

FIG. 1.—Buildings of Minnesota Seaside Station as seen across Station Cove. The large laboratory building is not shown, but stands immediately to the right of the smaller building. The buildings face nearly south.

The physiographic features of the shore in the vicinity of Port Renfrew, Vancouver Island, the nearest harbour to the Station, are extraordinarily favourable for the development of its special and characteristic work. The country rock is a tilted slate, cut by dykes of diabase and overlaid by millstone grit and sandstone. The bold promontory, just north of the Station, is of sandstone covered with glacial drift. The very broad shelving shore of sandstone is dotted with a great number of pot holes, worn by glacial boulders and ironstone concretions from the country rock. These pot holes vary in size and depth from little shallow saucers a few inches across to huge wells and cisterns many yards in diameter and often twenty feet or more in depth. Hundreds of such pools between tide marks serve as natural aquaria. Each has its characteristic distribution of plants and animals. For this reason, the Station shore is astonishingly rich in types of oceanic fauna and flora. Within a couple of miles, the formations change, and no other place upon the entire Alaskan, British Columbian or Californian coast is known to be so favourable for naturalistic study and research as that where the Minnesota Seaside Station has been built.

The thing of most importance about a seaside station is the sea. Minnesota, occupying a mid-continental position, might send its students with equal ease to the Atlantic or to the Pacific. It seemed, however, that a rallying point upon the Pacific would be the more inspiring. The eastern shore is already somewhat hackneyed and over civilised, so that the distractions of village life, golf, yachting and society may, in some circumstances, interfere with the free and genuine activities of a station. It is undeniable that, when a laboratory by the sea has acquired the appurtenances and refinements of a highly organised institution, something is lost on the side of Nature to counterbalance the gain in comfort and conventionality. The Minnesota Seaside Station, two thousand miles distant from the laboratories of the University of Minneapolis, behind the great plains and mountain ranges, sixty miles from any considerable settlement, free from the influence of morning newspapers, daily mails and inquiring tourists, has for its paramount source of interest and principal spring of enthusiasm the sea, and the sea alone.

From its site, three miles south of the harbour of Port Renfrew, visited four times a month by a little coasting steamer belonging to the Pacific Navigation Co., the Seaside Station looks out directly towards Cape Flattery. To the right roll the swells of the open Pacific. To the left, across the blue straits, rise, peak upon peak, the Olympics with their glistening glaciers, untrodden summits and eternal snows. There are few more beautiful spots in northern latitudes. One feels the magic of the mountains, the forest and the sea, and not to be a naturalist in such an environment is scarcely possible.

FIG. 2 Group of students holding an extended specimen of the Giant Kelp, *Nereocystis priapus*. The holdfast is seen hanging down on the right and the leaves are held upon the left.

During its first season, there were twenty-nine in attendance at the Station. In 1902, the number rose to

thirty-eight. Most of the party met at Minneapolis and journeyed to the coast in chartered cars which were cut off for several days in the mountains both going and returning. This enabled those who wished to climb some of the peaks in the vicinity of Banff, Laggan and Glacier. The whole region along the Canadian Pacific Railway from Banff to Mission abounds in problems for alpinists, and there is no better climbing in Europe or North America than that near Laggan, where Mounts Temple, Victoria, Hector, Hungabee and Lefroy, among the rest, are a perpetual challenge to the venturesome.

At the Minnesota Seaside Station, three buildings have been erected. One, a large log boarding house some thirty by sixty feet upon the ground and two storeys in height, serves as a camp. A smaller one-storey log house is used as a laboratory for zoology, and a two-storey frame building, twenty-four by forty feet in dimensions, is occupied by elementary and advanced students of botany. Lecture courses last year were conducted for the most part out of doors—either in the forest or upon the rocks by the sea. Indoor talks in connection with microscopic study of fresh material or around the fireplace in the large living room after dinner were also features of the work.

Several papers, both of a scientific and popular nature, and based upon observations or research at the Minnesota Seaside Station, have already been published. Some of these have appeared in "Minnesota Botanical Studies" and others in "Postelsia," the year-book of the Station, the volume of which for 1901 has recently come from the press.

Many useful phases of marine biological work have not yet been, and perhaps never will be, developed at Port Renfrew. There is an absence of dredging apparatus. No pumps, conduits or artificial aquaria have been installed, nor are the buildings supplied with electricity or gas. A serviceable steam launch is still one of the dreams of the future. Unlike most other marine stations, the one on the Straits of Fuca has never received any gratuities whatever from Government, institution, society or individual, but has been built and modestly equipped entirely through the cooperation of those who have enrolled themselves among its members. It is, in fact, organised somewhat like a club, and while unable to compete with the older stations in expenditure, nevertheless derives a certain advantage from its community of interest and independence.

For the use of the illustrations which accompany this article, we are indebted to the *Popular Science Monthly*.

FIG. 3.—Kelp-covered rock at low tide showing specimens of Alaria, Egregia and Halosaccion in characteristic attitudes. *Phyllospadix scouleri* appears in the foreground.

MR. CARNEGIE'S ST. ANDREWS ADDRESS.[1]

MR. CARNEGIE'S rectorial address at St. Andrews is an interesting study in the psychology of the typical business man of modern times, as well as a memoir on the conditions of great business, which people must read for the sake of the shrewd and acute remarks themselves, such as no statesman or economic student can afford to overlook. The address is written exclusively from the point of view of a great industrial chief who has availed himself to the full of the conditions of business in the most favoured and wealthy community which the world has yet seen—that of the United States. He has observed and seized the great opportunity for the concentration and development of industry on a large scale which the United States has afforded. A large area of complete internal free trade, and an active, vigorous and rapidly growing population throughout this area, have given the United States manufacturer for many years an unrivalled opportunity for colossal arrangements, involving the cheapening of cost by means of subdivision of labour and the institution of mechanical and automatic processes wherever hand labour could be superseded. This opportunity, properly used, has been the occasion of Mr. Carnegie's gigantic fortune, and it is accordingly natural that he should speak of all business as conforming to this type, so that a community like the United States supplies the model for great manufacturing business in future. The cheapness of production once established, it is assumed, will enable the United States to be the most successful competitors internationally, and Britain accordingly will take a second place in future, if not a third place, with Germany second. Naturally also, Mr. Carnegie regards the protectionist policy of the United States as having contributed to this result and given the United States manufacturer the monopoly of his large home market. Nor is it surprising to find the ordinary American idea about the economic effect of military armaments put forward by Mr. Carnegie as explaining the backward state of Europe compared with the United States. The ideas come from his environment and history, and the result of their combination with Mr. Carnegie's own shrewd observations is the present most instructive address.

The interest, however, is mainly psychological. Economically, there is nothing really new and true. Adam Smith explained long ago the economic gain of the subdivision of labour, the condition of manufacturing on a large scale, while the practical value of manufacturing on a large scale and for the largest possible market was exemplified first of all, not by the American, but by the Lancashire manufacturer, who had the home market of

1 A rectorial address delivered to the students in the University of St. Andrews, October 22, by Andrew Carnegie. (T. and A. Constable, 1902.)

the British Empire at his command as well as the general market of the less civilised nations of the earth. Where the United States has gone ahead has been in the special business of iron and steel, a development required by the more special conditions of industry in the United States, and not in every business requiring large markets. *Pace* Mr. Carnegie, also, it does not appear that the protectionist policy of the United States has favoured the development of great manufacturing. In iron and steel especially, the advance was favoured by naturally high prices attending the great demand for iron and steel, which was always producing a shortage in the old countries of Europe, especially Great Britain, such as we now witness in the United States itself. This recurring shortage, apart from the United States tariff, must infallibly have developed naturally the iron and steel industry of the United States, though Mr. Carnegie and others might have realised smaller fortunes than they have done in the process. As to Europe being overweighted in any way by military armaments, there is an obvious want of connection between the effect and the alleged cause. Extravagant expenditure is, of course, one reason why one community or individual should accumulate wealth at a lower rate than another community or individual, but extravagant expenditure on military objects has precisely the same effect, and no other, as any other kind of extravagance. Overbuilding, excessive outlay on dress or carriages, outlay on churches or theatres, are, or may be, forms of expenditure in which nations or individuals may indulge to their hurt as well as in armies and navies. Nor can the American community throw stones at any other community in this matter, as extravagance is one of the American's special vices, and there is one conspicuous case of this extravagance in the remarkable pension list which has grown up since the Civil War, and affects them economically much as a great debt or great expenditure on army and navy would affect them. Besides, when analysed, however great the outlay may be, the maintenance of armies and navies does not add to the cost of production in other industries in any country. The expense of these "luxuries," let us call them, is a deduction from the earnings of the community, so that there is, *pro tanto*, less to spend on other things; but the cost of producing these other things is not concerned.

While making these observations on Mr. Carnegie's theories, we cannot but agree with his view that the primacy of Great Britain as an economic unit is passing to the United States. The economic force of the United States is obviously the greatest single force of that kind; and the preponderance of the United States is increasing. This is no new idea. Mr. Gladstone and many others long ago pointed out how modern industrial forces were tending. People should weigh well, however, what Mr. Carnegie has to say in his own department as to the approaching exhaustion of the iron ores of Great Britain, a matter of common knowledge to those interested. Great industrial changes must follow this impending change. More interesting and surprising even is Mr. Carnegie's anticipation as to the exhaustion of the United States supplies themselves. "Even the United States," he says, "has a proved supply of first class ore only for sixty to seventy years, and a reserve of inferior grades which may keep her supplied for thirty years longer, say for a century in all, unless the rate of consumption be greatly increased. The enormous extent of territory in the republic over which ore can hopefully be looked for encourages the belief that new deposits are sure to be found." Germany, it is added, has the most enduring supply, although its ore is not nearly so rich as the American. All this points to great economic changes even more far reaching than what is implied by the exhaustion of iron ore in Great Britain only.

With many other observations, there must also be agreement, especially as to the importance of home markets, the diminishing importance of foreign trade and the like. There is, in truth, no distinction in essence between home and foreign markets. The proper distinction is between near, less near and distant markets which are all in their nature the same, the availability and accessibility in each case varying with every variety of goods and every variation in the conditions of transportation. Other things being equal, there is, of course, more exchange between near than between distant markets, and there are many goods and services where the exchanges are necessarily local.

The one weak point in the address is really what is said about the effect of European armaments, upon which comment has already been made. It may be admitted that, so far as there is insecurity and fear of invasion, Europe is politically less advantageously placed than the United States, and European business is, *pro tanto*, checked. But in itself, military expenditure is no worse than any other expenditure, and so far Europe is not handicapped in the race. We should like to throw out also for the consideration of Mr. Carnegie and other Americans whether they are not living in a fool's paradise so far as their supposed safety from invasion is concerned. If the United States fleet were to be defeated by a European Power, say by Germany, and circumstances were otherwise favourable, the territory of the States would not be safe from invasion. Descents upon the coast such as England was able to make in the War of Independence and in the war of 1812 might be repeated, and even a more serious invasion attempted. The American boast of their freedom from European militarism is one which it is not quite wise or safe to make.

R. G.

THE JUBILEE OF LORD LISTER.

On December 9, 1852, just fifty years ago, Joseph, now Lord, Lister passed his examination and was admitted a Fellow of the Royal College of Surgeons, thereby becoming a member of the medical profession. The jubilee of such an event abroad would have been made the occasion of a congratulatory address and of the compilation of a notable "Festschrift" to the honour of the great master of antiseptic surgery. Here we do things differently, and it has been reserved for the *British Medical Journal* to issue a Lister Jubilee number, in which eminent men of various nationalities give their appreciation of Lister's life-work.

Von Bergmann, of Berlin, contributes some remarks upon the use of iodoform gauze in operations upon the cavities of the body; Lucas-Championnière, of Paris, writes on Listerian methods of the present and of the future; and Oscar Bloch, of Copenhagen, upon the antiseptic system in Denmark; while von Mikulicz-Radecki, of Breslau, gives a contribution upon the treatment of fractured patella. Among the British contributors, Ogston, of Aberdeen, and Hector Cameron, of Glasgow, discuss the influence of Listerism upon military surgery and upon the evolution of modern surgery respectively, Watson Cheyne, of London, discusses Listerism and the development of operative surgery, while Annandale, of Edinburgh, writes pleasantly of early days, and Chiene, also of the Scotch capital, gives an account of the Edinburgh Royal Infirmary from 1869 to 1877—that is to say, during the time Lister held the chair of clinical surgery there. It is a notable number devoted to a notable man.

Although it is as the founder of antiseptic surgery that Lister's name will descend to posterity, his other achievements must not be forgotten. Into surgery he introduced many valuable methods of operative procedure and also the use of the catgut ligature, and his contributions to the

pathology of inflammation, the nature and mechanism of blood coagulation and the bacteriology of fermentation would alone entitle him to a place among the "Scientific Worthies." A characteristic trait of a great personality must have struck all those who had the privilege of working under Lister; this was his intense regard for the welfare of his patients. The writer well remembers Lord Lister's distress at some mishap which befell a patient, unforeseen at the time, but which, in the light of after events, might have been preventable.

Lord Lister's great experience has been called into requisition at least twice in recent years to aid the deliberations of those in whose hands the health of His Majesty the King has been entrusted, once when he was Prince of Wales and secondly in his recent severe illness. Lastly, as chairman of the King's Hospital Fund, he still continues his benefits to humanity. His various contributions to science and the honours bestowed upon him have already been detailed in NATURE, but it may be mentioned that this year he has been the recipient of the Copley medal of the Royal Society and of the Order of Merit. R. T. HEWLETT.

NOTES.

THE First Lord of the Treasury has appointed a committee to inquire and report as to the administration by the Meteorological Council of the existing Parliamentary grant, and as to whether any changes in its apportionment are desirable in the interests of meteorological science, and to make any further recommendations which may occur to them, with a view to increasing the utility of that grant. The committee will consist of:—the Right Hon. Sir Herbert E. Maxwell, Bart., M.P., (chairman), Mr. J. Dewar, M.P., Sir W. de W. Abney, K.C.B., F.R.S., Sir F. Hopwood, K C.B., Board of Trade, Sir T. H. Elliott, K C.B., Board of Agriculture, Dr. R. T. Glazebrook, F.R.S., Mr. T. L. Heath, Treasury, and Dr. J. Larmor, F.R.S. Mr. G. L. Barstow, of the Treasury, will act as secretary to the committee.

ANNOUNCEMENT has now been made of the Nobel prize awards this year. The awards include the following for science:—Medicine, Major Ronald Ross, School of Tropical Medicine, Liverpool; chemistry, Prof. Emil Fischer, Berlin; physics, divided between Prof. Lorenz, Leyden, and Prof. Zeeman, Amsterdam.

DR. BORDAS, assistant-director of the Paris Municipal Laboratory, has been awarded the Lacaze prize for his investigations in connection with typhoid fever. The prize is worth 400*l*.

DR. T. K. ROSE has been appointed chemist and assayer in the Royal Mint, in succession to the late Sir W. C. Roberts-Austen, K.C.B., F.R.S.

DR. SVEN HEDIN delivered an address before the Royal Scottish Geographical Society at Edinburgh on Tuesday. Sir John Murray, who presided, announced that the council had awarded Dr. Hedin the Livingstone memorial gold medal for the distinguished services which he had rendered to science by his explorations in Central Asia.

WE regret to see in the *Athenaeum* the announcement of the death of Prof. J. Wislicenus, professor of chemistry at Leipzig University.

COLONEL SIR T. H. HOLDICH has been appointed Knight Commander of the Order of St. Michael and St. George for services in connection with the Chile-Argentine Boundary Tribunal.

ACCORDING to the Paris correspondent of the *Times*, Prof. Lacroix, the head of the French Scientific Mission at Martinique, has reported that owing to the undermining of the point of the cone formed in the crater of Mont Pelée, masses of material have rolled down in the direction of White River, completely choking it. The ashes which filled the lower valley at a distance of six kilometres from the crater had still a temperature of more than 100° C. a week after they had been projected from the volcano.

WE regret to have to announce the death of Dr. Antonio d'Achiardi, of Pisa, in his sixty-fourth year. Dr. d'Achiardi was born and educated at Pisa, and had occupied the chair of mineralogy and geology in the University there since the year 1876. He was the author of treatises on both mineralogy and petrology, and published numerous memoirs, many of them relative to the mineralogy of Tuscany. Prof. d'Achiardi was an honorary member of the Mineralogical Society of this country.

THE following announcements of deaths, from yesterday's *Times*, will be read with regret by many men of science:—Prof. Millardet, professor of botany, first at Nancy and afterwards at Bordeaux, where his researches checked the ravages of the phylloxera.—Privy Councillor von Kupffer, professor of anatomy at the University of Munich.—Major Walter Reed, one of the foremost bacteriologists and pathologists of the United States. During the Spanish war he was a member of the board to investigate typhoid fever in the army. Later, he made several trips to Cuba and was on duty in Havana studying the diseases of the island as a member of the board to investigate the causes of yellow fever. As the result of investigations, the conclusion was arrived at that yellow fever is conveyed by a certain variety of mosquito, which, by its bite, introduces the disease into the blood of non-immunes. Sanitary measures for the destruction of the insect and for the screening of infected persons were at once put into effect in Havana, with the result that for more than a year no case of yellow fever has been developed there.

THE thirtieth annual dinner of the old students of the Royal School of Mines will be held on Tuesday, February 3, 1903, at the Hotel Cecil. The chair will be taken by Mr. A. C. Claudet. Tickets can be obtained from Mr. D. A. Louis, 77 Shirland Gardens, London, W.

THE fifth International Congress of Applied Chemistry will be opened in Berlin on May 31, 1903. Prof. Clemens Winkler will be honorary president, and Prof. Otto N. Witt, the president of the German committee, will occupy the chair. Dr. H. T. Böttinger is now actively engaged in securing the cooperation of British men of science. There will be twelve sections in all, at which every branch of pure and applied chemistry will be discussed.

THE annual meeting of the Geographical Association will be held on Friday, January 9, 1903, at 3.30 p.m., in the College of Preceptors, Bloomsbury Square, London, W.C. The president, Mr. Douglas W. Freshfield, will be in the chair, and will give an address. There will also be an address on the Australasian Commonwealth, by Sir John A. Cockburn, K.C.M.G., and an exhibition of maps, views and diagrams by lantern projections, illustrative of the Ordnance Survey maps, by Mr. A. W. Andrews.

THE success of the general meeting of the American Philosophical Society, held last April, established most satisfactorily the claim that the interests of useful knowledge in the United States may be greatly promoted by holding an annual general meeting of the Society. It was therefore decided to hold a second meeting, and in accordance with this resolution the meeting will take place on April 2 and 3, 1903. A strong and

representative committee was appointed to make the necessary arrangements, the chairman being Prof. George F. Barker, and secretary Mr. I. Minis Hays.

THE commission appointed a year ago by the legislature of New York to investigate and report upon the advisability of the State establishing an electrical laboratory will probably report, says the *Electrical World*, in favour of establishing such an institution, which will also serve as a standardisation bureau. It is reported that the commission has learned that the amount of capital in New York State directly interested in the development and use of electricity is 1,680,590,290 dollars, made up of 217,974,695 dollars, representing the capitalisation of the companies engaged in the manufacture of electrical apparatus, and 1,462,615,595 dollars, the capitalisation of the companies involving the use of electricity.

A PETITION to be presented to the council of the Chemical Society is now being circulated among Fellows of that body for signature, in which it is suggested that the council should take the opportunity afforded by the approaching resignation of the senior secretary, Prof. W. R. Dunstan, of limiting the period during which this office may be held, and so afford to the younger Fellows of the Society "an opportunity of gaining experience in this honourable official position." It is pointed out that such a limitation is already in force at the Royal Society.

A MEETING of the Imperial Vaccination League was held on Friday last, under the presidency of the Duke of Northumberland. The report was read by Mrs. Garrett Anderson, and it stated that the League would supply literature on the subject of vaccination for distribution, and that a body of lecturers would be organised to give addresses on the subject of smallpox and the protection which vaccination affords. In proposing the adoption of the report, the chairman referred to the extremely small fear of complications arising from vaccination now that calf lymph is used. The Bishop of Stepney, in seconding, remarked that educational work by the League was necessary in order to counteract the influence of societies opposed to vaccination. Sir Michael Foster, in moving the election of the executive committee, stated that an important point to consider was whether the sanitary authorities were the right ones to administer the Acts relating to the health of the people.

AT the annual meeting of the Yorkshire Naturalists' Union, held at Hull on December 10, Mr. W. Denison Roebuck was presented with a handsome testimonial in recognition of his past services as secretary of the Union and editor of the *Naturalist*. The presentation took the form of a beautifully illuminated address, in book form, and a clock and bronzes. References were made by many speakers to the ability with which Mr. Roebuck had worked in the interests of the Union. The presidential address was afterwards delivered by Mr. P. F. Kendall, his subject being "Problems in the Distribution of Animals and Plants." The new secretary is Mr. T. Sheppard, of the Municipal Museum, Hull, and the *Naturalist* will in future be edited by Mr. Sheppard and Mr. T. W. Woodhead, of Huddersfield. The president for 1903 is Mr. Roebuck, and Mr. J. H. Howarth is the treasurer.

THE Zoological Society of New York has acquired the Aquarium, which stands in Battery Park, New York City. It has been transferred to the Society by the City upon terms which provide for the entire control and management of the Aquarium by the Society and for an adequate maintenance of it by the City. The Society has appointed Mr. Charles H. Townshend, late of the United States Fish Commission, as director of the Aquarium. With him will be associated an advisory committee of experts, and the Aquarium will be managed by the Society in the same manner as the Zoological Park.

DR. J. W. B. GUNNING, Director of the Pretoria Museum and Zoological Gardens, sends us a long list of the additions to the menagerie of that institution which have been made during recent months. Amongst them is the celebrated lioness "Beauty," commonly called "Kruger's Lion," which was originally presented by the late Mr. Rhodes to the Pretoria Gardens in 1899 and returned to the donor by Mr. Kruger's orders. Mr. Rhodes then gave it to the Zoological Society of London, in whose gardens it remained for two years. At the special request of the authorities at Pretoria, the lioness was sent back there in July last, Mr. Rhodes's executors having signified their approval of this being done.

BY the death of Mr. Henry Stopes, the science of prehistoric archæology has lost an enthusiastic student and an indefatigable collector. By profession Mr. Stopes was an engineer, and he more particularly interested himself in Palæolithic implements viewed from the standpoint of a practical mechanic. He amassed an enormous collection of Palæolithic implements of all sorts, rightly judging that long series were all important in scientific study. He held that more could usually be learned from a rude or from an imperfect or unfinished implement than from the typical finished product, and thus he eagerly collected the "wasters" and the ruder and unfinished forms. In a short paper published in the *Journal* of the Anthropological Institute (vol. xxix., 1899, p. 302), he announced the discovery of *Neritina fluviatilis*, with a Pleistocene fauna and worked flints in high terrace gravels of the Thames valley, and in the following volume of the same *Journal* (p. 299) he published a paper on "Unclassified Worked Flints," illustrated by numerous specimens.

THE following candidates have been nominated for the Fellowship of the Reale Accademia dei Lincei:—As corresponding Fellows, Profs. Beccari, Donati, Lustig, Parona, Pascal and Venturi; as foreign Fellows, Profs. Lorentz, Thalèn, de Vries, Wiesner and Zeuthen. The Academy has been singularly unfortunate in its loss during the summer recess of the four ordinary Fellows General Annibale Ferrero, Prof. Adolfo Targioni-Tozzetti, Prof. Alfonso Cossa and Prof. Riccardo Felici, one corresponding Fellow, Prof. Magnaghi, and, on the list of foreign Fellows, Profs. Faye and Virchow. General Annibale Ferrero took a prominent part from the outset in the work of the International Geodetic Association. He held office in 1872 as head of the geodetic division of the Italian Military Topographical Institution, in 1893 as director of the Military Geographical Institution, from 1873–83 as secretary, and from 1883 as president, of the Royal Geodetic Commission for Italy, from 1891 to 1897 as vice-president of the Permanent Commission of the International Geodetic Association, and from 1897 until his death as president of the Association itself. Prof. Adolfo Targioni-Tozzetti started his career as a botanist, but in 1866 was elected to the chair of comparative anatomy and invertebrate zoology at Florence. In 1875, he was appointed director of the newly-formed Department of Agricultural Entomology at Florence. His most important writings are on entomological subjects, and include papers on the luminous organs of the Italian "lucciole," the classification of the Orthoptera and the vine diseases oidium and phylloxera. Alfonso Cossa was first assistant lecturer at Pavia in materia medica and botany; he subsequently held an appointment there as professor of chemistry and director of the Technical Institution; from 1866 to 1871 he was principal of a new technical institution at Udine, and then at Turin he held various posts, culminating in 1882 in a chair of chemistry

in the Engineering School of Valentino. His writings deal with agricultural chemistry, mineralogy and electro-chemistry, and his name has been perpetuated in the mineral Cossaite.

MR. E. ERNEST LOWE, curator of the Plymouth Museum and Art Gallery, sends a description and sketch of a portion of a mammalian tooth found by Mr. F. Leslie Sara, of Yelverton, in a cave in the Mendip Hills, Somersetshire. Mr. Lowe has identified the object, the greatest length of which is nearly six inches, as the terminal portion of one of the lower canine teeth of *Hippopotamus amphibius*. "The grinding surface of the tooth," he remarks, "is closely striated, and in the centre the striæ are so close and deep as to form a distinct groove, whereas all the recent hippopotamus teeth I have been able to examine have a *smooth* grinding surface. At the point of the tooth, the enamel is chipped as if from a blow. At first sight, the specimen appears to have been cut from the complete tooth with a modern saw, but I am assured it is exactly as found. The cut end was exposed on the surface of the clayey ground." Mr. Lowe suggests that the tooth is a prehistoric flint-flaker or axe-head of a unique character, but an authority to whom we have submitted the matter informs us that *fossil* hippopotamus tusks exhibit a structure exactly similar to that described by our correspondent. It is due to disintegration of the ivory along the lines of growth.

IN the *Journal* of the Society of Arts for December 5, there is a paper by Mr. Alfred Watkins on some aspects of photographic development, setting forth the methods of work that have become associated with the author's name. A few observations recorded appear to be new, as, for example, that an increase of iodide in a rapid emulsion may increase the multiplying factor for development, and that a little iodide of potassium in the developer causes the image to appear almost as quickly at the back of the plate as at the front. The tendency appears to be to find new circumstances that interfere with the most usual course of events in development, and from the discussion that followed the paper we gather that at least some authorities still regard Mr. Watkins's generalisations as of rather too sweeping a character.

DR. G. HELLMANN has recently published the sixth of his useful discussions of the rainfall of the Prussian States, prepared at the request of the German Meteorological Office. The part now in question refers to the Provinces of Schleswig-Holstein and Hanover; the annual distribution of rainfall is clearly delineated, as before, on a coloured map showing the amounts for each 50 millimetres from 450 to 1400, and upwards, with an inset exhibiting the interesting values for the district of the Hartz Mountains. Particular attention is given to the greatest falls in one day, and shorter intervals, as being of considerable utility to engineers and others. The variations in the annual amounts at the same localities are, as usual, very considerable, and depend upon laws of which little is known at present, the rainfall of a wet year being occasionally double the amount of that in a dry year.

WE have received vol. xi. of *Deutsche überseeische meteorologische Beobachtungen*, published by the Deutsche Seewarte, containing the meteorological observations made in German East Africa, collected and discussed by Dr. H. Maurer. The observations were made at thirty-three stations; some of them date back as far as 1894, and some have been published in other places. Although the series is not complete and the observations are acknowledged to be not all of the same quality, they give, in the main features, a useful representation of the climate of a large district hitherto but little known. In bringing the data together in one volume, by very carefully collating them on the most approved plan and by giving full particulars of the stations and instruments, the Seewarte has rendered a great service to meteorological science.

MR. FREDERIC J. CHESHIRE describes, in the *Journal* of the Quekett Microscopical Club, a simple form of reflecting polariser. It consists of a single glass reflecting surface fixed at a constant angle of $33\frac{1}{2}°$ with the axis of the microscope in the position commonly occupied by the mirror, and capable of rotation about that axis without varying the inclination. The author points out the advantage of the increased field as compared with that obtained with a moderate sized Nicol's prism.

THE November issue of the *Journal* of the Franklin Institute contains an interesting paper on the conversion of amorphous carbon to graphite, by Mr. F. J. FitzGerald, chemist to the Acheson Graphite Company. The paper is largely historical, the experiments of Despretz, Berthelot, Moissan and others being described in some detail.

SHORTLY after the great Indian earthquake of June 12, 1897, a duplex pendulum seismograph was erected at Shillong, a town lying just within the epicentral area of the earthquake. The records of this instrument from August, 1897, to the end of 1901 have recently been examined by Mr. R. D. Oldham in order to ascertain if any traces of tidal influence were to be detected in the occurrence of shocks in what at that time was an extremely unstable portion of the earth's crust. Mr. Oldham arrives at the following conclusions, which, however, he regards as provisional and requiring verification from a more extended series of observations. There is, in the first place, a large variation in the diurnal distribution of earthquakes, maxima of frequency occurring between 10 and 11 p.m. and between 6 and 7 a.m. Superimposed on this large but unexplained variation in frequency, there is a smaller variation, which has the appearance of being due to the tidal stresses set up by the attraction of the sun. Also, if this smaller variation is really due to tidal stresses, then the horizontal stress is much more efficient than the vertical stress, and the effect is less due to the amount of the stress than to the rate and range of its variation.

A RECONNAISSANCE-SURVEY of Jebel Garra and the oasis of Kurkur, which lie to the west of Assuan and the first cataract on the Nile, has been made by Dr. John Ball (Survey Department, Public Works Ministry, Cairo, 1902). Jebel Garra (540 metres above sea-level) is a huge, flat-topped hill capped by Eocene limestone, which stands on the margin of the plateau and scarps of Upper Cretaceous strata bordering the Kurkur Oasis. These overlook the low, undulating country formed of Nubian sandstone which occupies the intervening desert, where much blown sand occurs. The Kurkur Oasis is formed by the confluence of several wadies or drainage-channels, which have no outlet, and it contains two wells. There is little hope of the oasis being able to maintain more than a few human beings, and at present there are no residents. The water occurs at an altitude of 330 metres, and it appears to be derived rather from local rain water, which drains through the Cretaceous white limestone, than from any more permanent underground supply.

AN analysis by Mr. Radcliffe Hall of the volcanic dust which fell at Barbadoes on October 16 agrees in a general way with Dr. Pollard's analysis of the dust of May 7 (see NATURE, June 5). The material analysed by Mr. Hall contained rather more alumina and alkalis than that analysed by Dr. Pollard, and less magnesia; facts which point to the conclusion that felspar and possibly also glass are more abundant in the October than in the May dust.

A JOINT commission appointed by the Royal Society and the London School of Tropical Medicine has been investigating the African sleeping sickness. This disease, endemic in the Congo basin, has recently been spreading eastwards with great rapidity, causing a terrible mortality. Of the commissioners, Dr. Christie and Dr. Low (Craggs research student of the London School of Tropical Medicine) are returning home, but Dr. Castellani is remaining to complete his investigations. The latter has isolated a streptococcus which seems to be the specific cause of the disease. The *rôle* of the *Filaria perstans* as the causative agent has been disproved by the commission.

A NUMBER of cases of serious anæmia having occurred in the Dolcoath mine, Cornwall, an inquiry was instituted by the Home Office into the cause of the affection. Dr. Haldane, with whom was afterwards associated Dr. Boycott, made the interesting discovery that the condition was one of ankylostomiasis, which is due to the presence of an intestinal parasite, the *Ankylostomum duodenale.* This disease is almost confined to tropical countries, though it was met with among the navvies employed in the piercing of the St. Gothard tunnel. Doubtless, in the present instance, some of the miners who had been working abroad contracted the disease and brought the infection home with them.

IN the December number of the *Entomologist*, Mr. E. Bagwell-Purefoy gives further information with regard to the successful introduction of the brimstone butterfly into Tipperary, which was accomplished in 1894, after its feeding-plants had been planted a few years previously in the county. This butterfly —the *Gonepteryx rhamni* of some authors and the *Colias rhamni* of others—is found at Killarney and has been reported from Wicklow, but is not a native of any other part of Ireland. In 1896, the colony of Tipperary was found to be in a flourishing condition, and in 1901 and the present year had still further multiplied. During the past summer, Mr. Purefoy has attempted to introduce the handsome Mediterranean brimstone *G.* (or *C.*) *cleopatra* into the same district—an experiment which will be watched with interest.

IN the September issue of the *Proceedings* of the Philadelphia Academy, Miss A. M. Fields records the results of experiments made with a view of ascertaining the cause of the hostility to one another displayed by different colonies of ants of the same species, and likewise the influence of light of different colours on these insects. The chief cause of the hostility of one colony to another appears to be a difference of odour accompanied by a difference in the age of the individuals composing the two colonies. As regards colours, it is inferred that ants are able to distinguish some of these, but may have no preference for one more than another. Also that these insects gradually lose their natural dislike of light by exposure to its influence.

THE remarkable differences in the life-history of different colonies of an American land-planarian (*Planaria maculata*) form the subject of a paper by Mr. W. C. Curtis in a recent issue (vol. xxx. No. 7) of the *Proceedings* of the Boston (U.S A.) Natural History Society. In certain localities, the creature apparently reproduces its kind exclusively by fission, while in others sexual reproduction occurs. There are yet other districts in which both modes take place. It is suggested that the asexual may replace the sexual mode of reproduction in the same individuals, but to confirm or disprove this, an extended period of observation is essential.

THE third volume of Mr. W. S. Taggart's "Cotton Spinning" (Messrs. Macmillan and Co., Ltd.) has reached a second edition. The first two volumes deal with the preparing processes in cotton spinning, while this part takes up the subject of spinning and the preparation of yarns. Necessary additions have been made to the new edition so as to bring the book up to date.

IN the Christmas number of *Photography*, Messrs. Iliffe and Sons, Ltd., have presented us with an excellent and inexpensive publication, printed on good paper and studded with numerous fine illustrations by various processes. This number has set itself the task of reviewing and displaying the most choice samples that have been shown to the public at the two great exhibitions held at the New and Dudley Galleries this year. A short but interesting monograph accompanies each illustration, drawing the reader's attention to the chief points. The publishers seem to have spared no pains to make the production, as a whole, high class in every respect, and the book will be found useful and valuable as illustrating types of subjects and treatments which are utilised and cultivated at the present time.

THE additions to the Zoological Society's Gardens during the past week include a Ring-tailed Coati (*Nasua rufa*) from South America, presented by Mr. E. Bieber; a Banded Ichneumon (*Crossarchus fasiatus*) from Mozambique, presented by Mr. F. D. Samuel; a Raven (*Corvus corax*) British, presented by Mrs. Rose Haig Thomas; a Douglass's Horned Lizard (*Phrynosoma douglassi*) from the Rocky Mountains, presented by Mr. C. W. H. Doubler; a Hog Deer (*Cervus porcinus*) born in the Gardens.

ERRATUM.—In letter on p. 126, col. 2, l. 45, for "red out" read "red."

OUR ASTRONOMICAL COLUMN.

COMET 1902 *b* (GIACOBINI).—Further observations of this comet have been communicated to the *Astronomische Nachrichten* (No. 3833).

Mr. C. F. Pechule, of Copenhagen, made the following observation on December 3:—

14h. 38m. 20s. M.T. Copenhagen. $\Delta\alpha = -$1m. 22s.·00. $\Delta\delta = +1' \ 53''·7$. α (app.) = 7h. 17m. 26s.·56. δ (app.) = $-1^\circ \ 51' \ 18''·0$, faint, 12th magnitude, small, diffuse.

NEW VARIABLE STARS.—*Algol Variable*, 20, 1902, *Cygni.* —From photographs obtained by M. S. Blakjo, Madame Ceraski has found that the star having the position (1855) α = 21h. 0m. 44s.·6, $\delta = +45^\circ \ 11' \ 53''$, is a variable, and a further examination of ten plates indicates that it is a variable of the Algol type.

18, 1902, *Coronae.*—Mr. Thomas Anderson has observed that the star having the approximate position R.A. = 16h. 10m.·3, Dec. = $+38^\circ \ 8'$, (1855), has been rapidly decreasing in brightness during November.

The following magnitudes have been observed:—November 1, 8·5; November 7, 8·7; November 18, 9·2; November 21, 9·3.

19, 1902, *Pegasi.*—Mr. Anderson also records the variability of the star having the position R. A. = 21h. 57m.·8, Dec. = $+34^\circ \ 25'$ (1855). At maximum, its magnitude is midway between 9·1 and 9·9, whilst at minimum it is only 0·2m. brighter than a neighbouring 11th-magnitude star. Its period is seven months (*Astronomische Nachrichten*, No. 3831).

HERSCHEL'S NEBULOUS REGIONS OF THE HEAVENS.—Dr. Isaac Roberts has recently completed his photographic survey of the fifty-two regions of the heavens described by William Herschel, in his paper "The Construction of the Heavens" (*Phil. Trans.*, 1811), as exhibiting extensive diffused nebulosity, and has communicated the results of this survey to the Royal Astronomical Society (*The Observatory*, No. 325).

Using a 20 inch reflector and a 5-inch Cooke lens to obtain simultaneous photographs, he has obtained negatives showing stars of magnitude 16–17 with the former, and of magnitude 14–15 with the latter instrument, thus securing images of objects at least as faint as those shown by Herschel's telescopes.

These photographs show that in forty-eight cases out of the fifty-two there is no trace of the extensive diffused nebulosity described by Herschel. On the remaining four, there is nebulosity which forms parts of three extensive nebulous clouds, which, however, Herschel could not have seen in so complete a form as they are shown on the photographs.

NEW MINOR PLANETS.—Prof. Max Wolf announces, in No. 3831 of the *Astronomische Nachrichten*, the discovery of

nine new minor planets. Three of these were found on a plate taken by Prof. Wolf on November 20, three others on a plate taken by Mr. Dugan on November 21, and the remaining three were found on a plate secured by Prof. Wolf on November 21.

ELEMENTS AND EPHEMERIS OF COMET 1902 *d*.—M. G. Fayet, of the Paris Observatory, has computed the following elements and ephemeris for the orbit of the new comet, from observations made on December 3, 5 and 8:—

T = 1903 March 13·976 M.T. Paris.

$$\left.\begin{array}{rl}\pi = & 119^\circ\ 52'\ 40''\\ \Omega = & 117\ \ 39\ \ 21\\ i = & 43\ \ 53\ \ \ 9\\ \log q = & 0{\cdot}45401\end{array}\right\}1902$$

Ephemeris 12h. M.T. Paris.

1902	α h. m. s.	δ ° ′	log Δ	Brightness.
Dec. 11	7 14 47	−0 39·1	0·3339	1·1
15	7 12 58	+0 4·5	0·3255	1·2
19	7 10 52	+0 52·8	0·3179	1·2
23	7 8 33	+1 45·8	0·3110	1·3
27	7 6 1	+2 43·3	0·3049	1·3
31	7 3 18	+3 45·1	0·2999	1·4

Brightness at time of discovery = 1.

An observation was made on December 10d. 13h. 37m.·0 at Heidelberg by M. Courvoisier, and gave the following position for the comet:—108° 47′ 12″, − 0° 48′ 15″, and this gives a correction to Fayet's ephemeris of −2s. and +0′·6 (Kiel *Circular*, No. 55).

"COMPANION TO 'THE OBSERVATORY,' 1903."—This annual collection of elements and ephemerides, just published, contains its usual excellent list of tables and information in regard to the astronomical phenomena which will take place during the coming year.

The information concerning the various meteor showers and double stars is supplied by Messrs. Denning and Maw respectively, and M. Loewy has again contributed advance proofs from which the variable-star ephemerides have been compiled. The latter show a considerable increase in number this year.

JUPITER AND HIS GREAT RED SPOT.

THOUGH Jupiter has been unfavourably placed for European observers during the present year, his surface markings have been extremely interesting, of great variety and in plentiful numbers. The English climate, even at its best, can scarcely be said to suit astronomical work in an eminent degree, but its characteristics in 1902 have proved unusually bad, in fact, atmospheric conditions have combined with the low position of the planet to render observations difficult, and they have generally had to be pursued with definition of very inferior quality. The seeing has been recorded as "very good" on six nights only out of seventy-five, and in 1901 the result was equally disappointing, for the image was really sharp and satisfactory on five nights only out of seventy-one; but in 1901 the planet was about 5° lower (Dec. 23° S.) than in 1902 (Dec. 18° S.), and though the difference is not great, it ought to have operated strongly in favour of the present year had other circumstances been equal.

The most noteworthy incident in connection with recent studies of Jupiter is to be found in a very pronounced acceleration of motion in the great red spot. This first made itself evident in 1901, but it has been intensified during the past summer. For about twenty-three years, uninterruptedly, this singular marking had exhibited a constantly increasing retardation, which caused its rotation period to lengthen from about 9h. 55m. 34s. to nearly 9h. 55m. 42s. But in 1901 it declined to 9h. 55m. 41s., and during the present year the rate has been about 9h. 55m. 39½s. And this increase of velocity has been contemporary with the outbreak of a large, irregular or multiple marking of a dusky hue, in the same latitude of the planet. This new object, apparently first seen in May, 1901, has shown a rotation period of 9h. 55m. 18s., which corresponds with that of the south temperate current. It seems a probable conjecture that the presence of the marking just referred to may have forced the red spot along at a more rapid rate than that which it exhibited in previous years. In June, July and August of the present year, the red spot was almost surrounded by the material of the new marking, and the quicker motion of the latter may well have accelerated the movement of the former. But no certain conclusion can be arrived at, though the facts are significant and suggestive. Possibly the phenomena alluded to may have been practically coincident in date, but devoid of any physical relationship. And in this connection it will be useful to remember that the red spot has always been situated in a stream flowing along with much greater celerity than the rate of its own motion.

In September, the material of the new marking had passed to the preceding (W.) side of the red spot, and hence it was expected that the accelerated motion of the latter would cease, but the differences in motion have been comparatively slight, so that errors of observation make it unsafe to form definite conclusions. It will be advisable when the planet disappears from the evening sky in January next to collect all the transit times of the red spot recorded during the present apparition, as it may then be possible to determine with accuracy the extent of the acceleration and the variation in its rate, if any, during the summer and autumn. If a large number of observations are forthcoming, it will be desirable to group them into monthly or bi-monthly periods and ascertain the mean longitude of the spot for each of these, when the rate of its drift will be seen and the errors of individual transits practically obliterated.

At Bristol, the following estimated transits have been obtained with a 10 inch reflector and a power of 312:—

Date. 1902.	G.M.T. h. m.	Longitude. °
April 28	16 14	45·9
May 20	14 23	44·7
June 20	14 56	44·8
,, 27	15 37	42·2
July 2	14 49	45·1
,, 7	13 54	43·9
,, 9	15 33	44·5
Aug. 8	10 8	40·2
,, 12	13 29	41·7
,, 15	10 57	42·5
,, 20	10 3	41·7
,, 25	9 7	39·6
Sept. 1	9 50	38·0
,, 13	9 48	40·3
,, 18	8 56½	40·5
,, 28	7 9	37·9
Oct. 3	6 18	37·9
,, 10	7 9	40·2
,, 15	6 13	37·1
,, 22	7 1	37·1
Nov. 8	6 8	36·9
,, 18	4 31½	39·4
,, 23	3 36	36·1
,, 25	5 20	39·1

During the present year, a number of white and dark spots have been visible on the north side of the north equatorial belt, and the mean rotation period of these has been about ten seconds less than that shown by the red spot. A new belt has lately formed on the northern side of the spots alluded to. The equatorial current of the planet has been moving, as nearly as possible, at the same rate as during 1901, for the mean rotation of twenty-four spots is about 9h. 50m. 29s. There has been an abundance of slow-moving N. and N.N. temperate markings, but these have seldom been well seen owing to the confused definition.

W. F. DENNING.

SOME LIMITS IN HEAVY ELECTRICAL ENGINEERING.[1]

IT is customary for a presidential address to be a review of the development of the science with which the Institution is particularly concerned. Such a review is especially beneficial in the case of such a rapidly growing industry as electrical engineering, as the outlook changes considerably during a year. Instead of a review of the past, a dream of the future may take the form of a presidential address. This form has great

[1] Abridged from the inaugural address by the president of the Institution of Electrical Engineers, Mr. James Swinburne.

attractions for me for several reasons. In the first place, this kind of prophecy is easy and pleasant. I might draw a rosy picture of a future when everything conceivable is done electrically. We shall have electrical energy developed direct from carbon at the coal-pits. Not only all our lighting, but all our domestic heating will be done electrically. There will be no smoke in our cities or in what will correspond to them. Most of the dirt of our houses will have vanished. Large and crowded towns will have disappeared, because the telegraph will have given way to its wireless rival, and that will have given way to the wireless telephone with no exchanges and no subscriptions. There will thus be no need for people to go and see one another to transact business. Even when matters must be written to preserve a record, no office will be necessary. You will dictate by wireless telephony to your shorthand clerk at his distant house. Perhaps we shall all learn shorthand instead of our present cumbersome system of writing, and all books and letters will be in one language, written and printed phonetically at speaking speed or faster. The horse will have gone, leaving clean and odourless streets, with smooth surfaces on which people will travel in rapid electric automobiles. The railways with very rapid long-distance service will be entirely electric. It is very easy to prophesy in this sort of way, not only in a general way, but in considerable detail; and it is an amusement that brings much credit to the prophet. If any of his prophecies seem unlikely to come true, he merely has to say, "Wait a little!" While if anything like what he foretells comes into existence, say twenty years hence, all he has to do is to refer back to an address to claim that he has foretold it, and the future inventor will have half his credit taken from him and given to the prophet. If the prophecies are sufficiently vague, there is certain to be some sort of fulfilment of some of them sooner or later, and it is always well to have a good many past publications of this sort in stock waiting for future development.

Great though the temptation is, I will resist it, and try to look into the future from quite a different point of view. We have been going ahead so very fast lately—even our acceleration itself increasing—that we may be a little apt to have vague views of what we can and what we cannot do electrically. It may be well, therefore, to try to look over some of the branches of our great and diverse industry, and see what obstacles are now opposing us and what are likely to oppose us shortly, and whether the obstacles are insuperable or not. This sort of prophecy is much more difficult than the other, for there can be no credit twenty years hence in having said something could not be done, even if it has not, while if it has been accomplished the position is still more difficult. Negative prophecy is thus unattractive. But the discussion of our limits may not only have a beneficial effect in making us modest, but it may be a much greater benefit if, by focussing our attention on a limit of any development, we find either that the obstacle is theoretically insurmountable, in which case we must go round it, or that it has to be scaled in a particular way.

There are clearly at least two kinds of obstacles. For instance, it is obviously impossible to get more than 746 watts out of a dynamo taking one horse-power to drive it. But the limit of possible speed on an electric railway belongs to quite a different category. I will therefore discuss various branches of electrical technology, to see what may prevent or is preventing further advance.

Twenty years ago, this Institution was chiefly concerned with the development of the telegraph. We can get but few telegraph papers now. This is not because telegraphy is dead; it is because most of its problems are solved, so there is little to discuss. The fact that there is little to discuss in telegraphy is the proof of its vitality. It has passed out of the childhood of technical difficulties into the manhood of commercial development. Ten years ago, we were in the thick of the evolution of the dynamo and the transformer. Now there is little but detail to discuss about electrical generating machinery. This is because heavy electrical machinery has got through its difficult infancy and is now a trade, which is the highest compliment that can be paid to it. But we electrical engineers have also developed through our difficult training into being the scientific branch of the engineering profession. Our exactness of calculation and measurement has leavened the steam engineers and the other manufacturers with whom we have to work in concert.

No one man can be a complete electrical engineer; but each of us ought to know one subject well and a large number of allied subjects fairly well. As a basis of technical knowledge, which I am alone dealing with to-night, we must have a fairly all-round knowledge of "theoretical" physics and chemistry. Physics is merely unapplied engineering. Science is split—unfortunately, the split is very difficult to heal—into two parts, generally wrongly called the theory and the practice; or pure and applied science. This fissure is not so deep in our branch of engineering, but it is there. Science, to be worthy of the name, is knowledge of Nature utilised by man. Engineering is science, and science is engineering. You can cut off a part and call it unapplied science. This is what is generally known as theory or pure science. It is not purer than any other science, and the term theory is misapplied. To be an engineer you must know both branches. There is nothing superior about knowledge which is not yet applied. It is mere raw material; it may be useful when worked up, and it is valuable before it is worked up, but only because it may be worked up. The so-called practical man who works at applications without understanding the generalised principles is ignorant. He only understands a part of science. The so-called scientific man who only understands what is called pure science is just as ignorant. Each understands part of his subject only.

We as electrical engineers ought especially to heal the split between the halves of science; a split which is much deeper in other branches of engineering, such as chemical and purely mechanical. We ought to unite knowledge of both branches of science in one individual as much as possible.

Tides.

The tides are often referred to as a possible source of energy even to this day; and it is urged that in places where the tide rises abnormally, for instance in the estuary of the Severn, it would pay to make a dam with turbines. The sort of argument is that if you have an area of, say, 1000 square metres and a total rise of 15 metres, you have 15,000 cubic metres of water, and as this runs in twice and out twice a day, you have 15,000 cubic metres of water, falling the equivalent of 60 metres a day, or approximately 100 kilowatts. This statement contains many fallacies. In the first place, in order to get the full advantage of the difference of level, the water must be let in and out at high and low tide only. Even then the equivalent or average head during discharge or charge is only $7\frac{1}{2}$ metres. But a system which gave an enormous power for a very short time four times a day would be of no use. The plant would be expensive and the result of no value. With a single tank it is impossible to get a continuous output. If the tide is coming in and you get power by letting the tide fill the tank, the power will decrease to zero as the tide begins to fall and comes to the same level as the water in the tank. It is therefore necessary to have more than one tank. To make the plant practical, you want fairly constant pressure available on the turbines, though you may waste head by sluices or valves. It is often said that a Norwegian fiord or a Scotch loch could be easily dammed and utilised, but it would be impossible to find three lochs all opening out together. The need for more than one reservoir does not seem to have been recognised. In addition, the demand for electrical energy on Scotch lochs or Norwegian fiords is rather minute.

Water Power.

Some years ago, there was a great deal of excitement about the development of water powers. The possibility of "harnessing Niagara" and utilising waterfalls all over the world was hailed as a great triumph over Nature, and the idea was that power could be got for nothing, and industries would all migrate from coal districts to the neighbourhood of water powers. The daily Press and the magazines took the matter up, and there is something in the idea of saving some of the colossal waste of natural energy that appealed especially to the half-scientific or unpractical reader. At the time of the excitement, it was pointed out, largely in vain, that water power did not cost nothing, because the development of a fall demanded a good deal of capital, on which interest and depreciation had to be paid. But further than this, Ricardo's theory of rent is applicable to water powers as well as to arable land. If steam power costs a farthing a unit, and if water power at the same place can be produced for half a farthing, after paying working expenses and interest, the owner of the water power will claim the odd half farthing as rent, or will just allow the water power enough to encourage the production of a new thing. As a rule, however, a water

power is not where it is wanted industrially. In the nature of things, water powers are generally in hilly countries, and are seldom near the sea. The result is that a water power as a rule cannot command the same price as steam or gas, because it is not where it is wanted. The idea in starting many of the water-power stations also was that works which needed power would come and settle near. As a matter of fact, the cost of power is a much smaller item in most industries than is generally supposed, and it does not pay to start a works in an otherwise not perfectly suitable locality simply for the sake of the cheap water power. In such industries as engine building, flour milling, spinning and weaving, and so on, the chance of reducing the expense for power is not enough to overcome other considerations. It may be said that in electro-metallurgical processes the whole cost is practically the electrical energy, and so carbides, aluminium, electrolytic soda and chlorate of potash will be made at water powers. Even this, however, is misleading. Carbides and aluminium are generally made at waterfalls, and chlorate nearly always is. Electrolytic soda and bleach are made at water powers, but are also made extensively by steam-driven plant. Against the cheaper power, we have to put extra carriage for materials and for coal, which is often needed in addition, and extra carriage for finished products, and very often extra cost of labour, as labour is often dear and bad in water-power districts. It may thus easily pay to use much more expensive power if the other conditions are more favourable. Steam power, for instance, will cost three or three-and-a-half times as much, and yet it pays to make electrolytic caustic and bleach in England where the other conditions are all favourable. It is not, therefore, the want of water power that has kept the electrolytic industry back in this country. For a water power to be really valuable, it should be near a source of material, on the sea, and should have a great head of water, so that the capital cost of development is small. Such a water power is very valuable—to the landlord.

A blast furnace is more valuable than a water power. There are plenty in England. But the owners, who have been wasting the gas up to now, will not give it away; they will want rent, so that it will only just pay to use this gas rather than make it. The electrical industry thus does not gain, but the ironmasters do.

Carbon Cells.

For many years, "electrical energy direct from coal" has been the dream of the electro-chemist. That is to say, he has dreamed of an electrolytic cell in which the consumed electrode is carbon. The best way to realise the difficulties of this problem is to consider it solved and see what it means. The carbon must be in contact with an electrolyte, and that electrolyte must either be in contact with a second electrolyte which wets the other electrode or must itself be in contact with that electrode. This second electrode must almost certainly be metal, as there are no other non-metallic conductors available. Such compounds as the hydrides, nitride, oxides, chloride, bromide, or the sulphide, or silicide, of carbon are not salts in the electrolytic sense. Carbon forms part of the electro-positive radicle in the organic radicles and part of the electro-negative radicle in the cyanogen compounds, but it is never a radicle by itself. To sum up the matter shortly in the light of modern theory, carbon never forms ions, and has therefore no solution pressure, and can therefore give no electromotive force. At ordinary or moderate temperatures, carbon is practically inert. Oxidising agents will attack some forms slightly, and sulphuric acid will attack it. In this latter case, the formation of water and its combination with the acid is the determining factor. At high temperatures, oxygen, sulphur, silicon, and to some extent nitrogen, and many of the metals combine with carbon, but there is no dissociable salt of carbon formed. The carbon cell thus seems impossible. Such schemes as Mr. Reed's, ingenious as it is, is not a solution of the problem. It would be simpler to reduce zinc oxide with the carbon and then put it in a zinc cell.

It is hardly necessary to discuss thermopiles or thermomagnetic engines as possible economical producers of electric power.

Steam Engines.

The primary question in all heat motors is, What temperature range is available? In the case of a steam engine, there is enormous waste of mutivity—to use a variation of Lord Kelvin's convenient term—in boiler flues. We burn carbon and hydrogen, capable even with air of giving a temperature of some 1500° C., and the heat is degraded down to some 200° C. That is to say, instead of getting the heat with a mutivity of about 0·825, we degrade it down to, say, 0·35, a clear loss of 0·45 out of 0·8, or 56 per cent. This degradation is apart from the efficiency; the efficiency is concerned with the loss of heat up the chimney. The higher limit in large modern reciprocating engines may be taken, roughly, at 600° A. (327 C. or 620° F). Above this, there is difficulty in lubrication and to some extent weakening of the material. The pressure corresponding to this temperature for saturated steam is out of the question, and the pressure may be taken at, say, 12·5 megadynes per square centimetre or 12½ atmospheres, or 200 lb. per square inch, and steam leaving the boiler superheated to 600° A. does not get at the cylinder lubrication at that temperature. Our limits in the steam engine are thus pretty clearly defined. The pressure is the essential factor. Superheating is not much good in the way of getting higher mutivity in the boiler, nor is it very important in getting much more energy into the steam.

The turbine is under the same limit as regards pressure; in fact, high pressures are perhaps even more difficult to use, and superheating does not, as already explained, seriously increase the mutivity of the heat taken in by the boiler.

One of the chief disadvantages of steam engines for stations with small load-factors is the difficulty of storing energy so as to get uniform boiler load. Batteries are no longer used for this, and the difficulty reduces the value of steam in comparison with the gas engine. Mr. Druitt Halpin has proposed, and used, "thermal storage." Lagged vessels are filled with water raised to the temperature of the working steam. This arrangement, however, is not isothermic; that is to say, to get out the energy the temperature must fall. What is wanted is a reservoir containing something which undergoes a physical or chemical isothermal change. For instance, a substance that fuses at the right temperature and has a high latent heat of fusion, or a substance which, like sulphur, changes allotropically with considerable change of internal energy, at a suitable temperature. Unfortunately, there is no substance within the range of practical engineering. Moreover, the storage is on the wrong side of the engine. To store heat with a mutivity of only some 0·35 is not so promising as to store some higher form of energy. The secondary battery thus begins with an apparent advantage. The difficulty of storage is another drawback to the steam engine, and gives the gas engine a further advantage.

The Gas Engine.

There is no other comprehensive name that covers the type of engine worked by gas and oil. The combustion need not be internal, and perhaps will not be internal in the future, but in a sense all are worked by gases.

We have in the gas engine a machine which, from a thermodynamical point of view, ought to be exceedingly good; but the difficulties in building, especially very large engines to utilise the high possible mutivity and saving by having the heat produced where used, reduce the efficiency of the gas engine enormously. In spite of that, the large gas engine seems likely to oust the steam engine for large powers during the next few years. The best way to get a high efficiency out of a gas engine would probably be to make it compound, exhausting at a temperature suitable for raising steam. The steam engine would then exhaust at a temperature suitable for raising SO_2 vapour. But the chances are that Dowson, Mond or other producer gas will be available at such low prices that the extra steam and dioxide engines would not pay for attendance, interest and depreciation. With very cheap gas, the first thing is to make big engines, the next to make them so that they never break down, and the last thing to make them efficient. The gas engine may be, comparatively speaking, in the state Watt left the steam engine, but it will doubtless make very rapid advances, as it is in the hands of very competent and highly educated engineers.

Dynamos.

As regards efficiency, we have reached the practical limit already, for further reduction in dynamo losses would make no appreciable difference in the total efficiency of a station. In fact, we are rather following continental practice in having slow-running machines with many poles, even for direct currents, and efficiencies are perhaps lower for large machines than in the best English practice of a few years ago. This is also true as regards output from a given size. We are not likely to make much advance in dynamos now, as we are limited on

one hand by the hysteresis loss in iron, which prevents our using higher inductions in armatures, and low permeability, which limits our field and armature tooth inductions. It does not seem likely that we shall now find iron much better in either respect. Nor are we likely to find a better available conductor than pure copper. As insulator we have mica. It looks, therefore, as if we were within sight of our limits in dynamo and motor designs.

Secondary Batteries.

The secondary battery in central station work has been used as a store to equalise the load, and to reduce the running plant at the times of heavy load. Owing to the high full-load station pressure with feeder systems, the station battery is generally for use at light loads only. But the secondary battery has for a long time been on the border of success for traction work, both on tramways and on the road, and a further improvement in batteries may be expected to produce very great changes in important branches of engineering.

The first question asked is, Why do we stick to lead? The answer is that the case is very special and other things will not do. We are practically limited to lead, at any rate in acid cells. Take first the plate that oxidises on discharge. It should not dissolve in the electrolyte, as if it does the deposition and solution will be uneven, and the plate will grow trees and come to grief. This puts zinc out of court, unless some electrolyte is used which gives some insoluble salt of zinc, which does not attack zinc on open circuit, and gives a good electromotive force with it. Iron is out of court for the same reason; there is no suitable electrolyte. The strong organic acids such as trichloracetic or oxalic are apt to have their positive radicles split up by electrolysis, even if a strongly positive metal can be found with an insoluble salt. Lead is thus the only metal practically available in an acid electrolyte. Silver in hydrochloric acid would give no pressure, and the acid would be decomposed at the anode. On the other plate we need an insoluble depolariser, else a two-fluid cell must be used, involving a porous diaphragm, diffusion and impracticability. Not only must the depolariser be insoluble, but it must be converted into an insoluble body on discharge. The coating must be a conductor in one state or the other, or there will be no proper contact. In the lead cell, there is always enough peroxide and metallic lead in the coatings to secure electrical contact though the discharge product is an insulator. The depolarising coating must be connected to a conducting plate which is not attacked by local action. Lead and silver are the only available metals, and sulphuric, and perhaps phosphoric, the only acids, for the nitrate of lead is soluble and hydrochloric acid is decomposed by lead peroxide. Lead is protected by its coating of sulphate, or peroxide as the case may be. It thus seems as if we were limited almost absolutely to lead and sulphuric acid. It is wonderful that we have the lead cell at all. We owe it to the chance observation of Planté. The theory was not understood for a long time. For many years it was thought that the pressure was due to the PbO_2 and Pb changing into PbO. The acid was merely put in to make the electrolyte conduct, and sulphuric acid was used because people used it in gas voltameters, and they never thought that it ought to be as strong as practicable to give the pressure and output. The formation of lead sulphate was regarded as a difficulty to be overcome.

In the lead cell we want lightness, large capacity, cheapness, rapid discharge, efficiency and mechanical strength, and durability. These qualities are mostly antagonistic. Large capacity means rapid deterioration. Mechanical strength means weight. It is thus no use testing a cell for capacity without testing the efficiency and durability too, and so on. Published battery reports are often misleading, because they omit essential information.

Cables.

The conductor itself can hardly be improved, but there is great room for improvement in the insulation. It is largely the insulation of the cables that limits our pressures, and therefore our distances of transmission. For 1000 kilowatt cables, the cost is about a minimum for 8000 volts; above that, the cost of insulation increases faster than the cost of copper falls. It is exceedingly unlikely we have reached the limit in insulation. There is no branch of electrical engineering so important as cable making. Cables form a large portion of the capital outlay in large systems. Yet there is no branch of the industry which is run on less scientific lines. The days of secret mixtures known only to the workman who makes them may be passing away; but even now the whole art of cable-making is a question of trial and error, with a good deal of the last component. Engineers do not know now whether rubber is better than paper, nor can they tell what any particular make of cable will be like after ten years' use.

Light.

Our chief work, until lately, has been producing light. Here the inefficiency and waste is prodigious, and though it is mostly unavoidable, there is still great room for improvement. We take great care over our stations, watching every penny from the coal shovel or mechanical stoker to the station meter. We quarrel over 1 per cent. in the generators. When we get to the mains we care less, and once we have got to the consumers' meters we care nothing at all.

Practically all light is wanted for use by the human eye. The human eye is exceedingly sensitive; it is calculated to see a distant star when receiving 10^{-8} ergs per second, so that one watt would enable, say, five thousand billion people to see stars with both eyes, but it would have to be used economically. In reading a book, the eye would need much more than this; and then, as the book radiates light in half of all directions, only a little is used by the eye, so even if all the light from a source were concentrated on a book, there is enormous waste by useless radiation from the book. But the source of light does not illuminate only the book; the book probably subtends a small solid angle, so we have another source of waste. The eyes reading a book in a fairly good light want something of the order of two ergs per second, so that a watt would only work the optic nerves of, say, the inhabitants of London. But the book, say 200 square centimetres, would need about 3000 ergs a second to illuminate it. A candle, which gives a light of 4π, radiates about 0·2 watt, or five candles a watt; that is to say, at an efficiency of unity, we would get five candle-power or 20 units of light per watt. The efficiency of a glow-lamp is only about 0·25 candle-power per watt, or 0·05, so there is room for improvement. The first thing, naturally, is to see what limits there are in the way of increased efficiency. The obvious goal is direct production of "light without heat," by which is meant producing only the rays of wave-lengths which affect the eye.

There is no thermodynamical reason why electrical energy should not be converted directly into radiation of any wave-length without loss; I do not know if there is any molecular impossibility, but apparently our limits are practical—that is to say, it may be done, but we have not yet hit on the way of doing it. The vacuum tube appears to be a means of converting electric power direct into radiation. The Cooper-Hewitt lamp, for instance, gives an efficiency of about three candles per watt, or something like 0·6. All these figures as to light are a little vague. Unfortunately, the light is of a very bad colour. It is very actinic, but the wave-lengths are too small. One method is to degrade the light by making it act on silk dyed with matters which lower the radiation to a redder colour by fluorescence.

The Arc Light.

The arc has been very fully studied in some directions and not in others. Most makers of arc lamps seem to devote their whole attention to the mechanism, and look upon the arc merely as a hot gap that has to be preserved by suitable apparatus. Many lamp makers, on the other hand, have records of exhaustive experiments on the relations of the pressure, current and light with different carbons; but they are very seldom published. On the other hand, an enormous amount of laborious experiment on such points as these is available, and on the back electromotive force of the arc. The physics of the arc, an exceedingly difficult branch of study, has not received much systematic attention yet. The crater of an arc is, no doubt, heated to the point of volatilisation of carbon at the pressure of the air. If other gases get at the crater, the vaporisation temperature would be less. (There is a small increase of pressure which I suggest is due to the electromagnetic effect of a current localised in a conducting fluid. This may be neglected.) The crater may be rough, as carbon, though it softens, does not melt before volatilising, and it may be merely speckled with points at its volatilising temperature, so that its brightness is not uniform. But there are so many anomalies about the arc that one cannot say anything definite with safety. For instance, if the temperature is limited by the vaporisation of carbon, what must be the specific heat of vaporisation of carbon? Where does the vapour go, and what happens to it in an enclosed lamp? In condensing into smoke, it should give light of the

same colour as the crater. If it has an enormous specific heat, it ought to raise the other pole to crater temperature where it condenses. If it is a light gas, a large portion of its specific heat of vaporisation may go to external work. Most of the upper carbon is burnt away by external air; if a pencil to match the crater is volatilised, it does not account for much power. If the vapour is very light, there must be large volumes from the upper carbon. Then what conducts? Carbon vapour alone, or mixed with a little monoxide or nitrogen, is a very good conductor at these temperatures. Does that go to show that carbon vapour dissociates like iodine or chlorine, &c.? The whole question of the physics of the arc deserves far more careful study than it has yet received, but the work is surrounded with difficulties and is really a branch of the theory of the passage of electricity through gases, a matter of the greatest scientific importance, somewhat out of our way as practical electrical engineers. But as engineers in the broader sense, we are as much interested in questions of recondite physics as of costs of generation.

To sum up as to the arc light, we do not seem to have reached our limit as to light from pure heating, because we lose a lot of light into the opposite carbon. Many attempts have been made to expose the crater freely. But, far more important than this, I would urge that the arc is not necessarily a hot body radiator only, but that it may also convert electrical power directly into light in the space between the electrodes, and this gives a chance of rising more nearly to our theoretical limit of about five candles per watt.

The Incandescent Lamp.

This simple hot carbon wire in a bulb involves the most extraordinary physical complexities. A great many curious things go on inside the simple-looking globe. A good account of what is known—especially since he took the subject in hand—has been written by Dr. Fleming, and the scientific manufacture of this interesting article has been fully described by Mr. Ram. The incandescent lamp is a simple hot body radiator, and the limit of efficiency depends chiefly on the temperature of the carbon. As we are limited by the size of mains, we can only use pressures of 100 volts or 200 volts, and this limits us to carbon or something of still higher specific resistance. The sensitiveness of the carbon lamp to pressure in its turn limits the practical variation of pressure of supply, and thus costs us very heavily in mains. If we had incandescent lamps which did not mind 20 per cent. pressure variation, we would have saved millions in mains in this country alone.

The idea of making lamps of carbides has become very fashionable lately. People have put oxides into carbon for the last twenty years. The old idea is to get hold of an oxide that radiates more light at a given temperature than it ought to, which is itself a fallacy, while the idea of oxide in contact with carbon is chemically absurd. There is no oxide irreducible by hot carbon. The carbides are not by any means all refractory. Some are, though, but there are immense difficulties in making carbide lamps. To make a fine filament material of an infusible material, which can be made only at electric furnace temperatures and is generally decomposed by moist air, is not an easy task. It is easy to think you have made a carbide lamp by incorporating an oxide in the filament material, but the resulting filament is generally mostly, if not wholly, carbon. What happens to the metal in the circumstances is rather a mystery. There is, however, a chance of enlarging our limits in incandescent lamps of the ordinary kind, but it seems strange that the melting points of all known materials should suddenly reach a higher limit. Assuming the Stefan-Boltzmann law for ordinary light radiations, the fact that the efficiencies of refractory bodies all reach limits of the same order shows that the most refractory bodies melt at about the same temperature, somewhere in the neighbourhood of 3000° A. Whatever the inter-molecular forces may be that bind the particles to make solids, the vibration forces due to temperature seem to overcome the greatest at about 3000°.

Instead of an ordinary conductor, Nernst uses an electrolyte which stands a higher temperature. The conduction is electrolytic, as can easily be shown, but there are many curious phenomena, many of them so far unexplained, in the Nernst lamp. The efficiency of the Nernst lamp is about 0·6 candle per watt. It was at one time supposed to owe its efficiency to selective emission, but there is no reason to doubt that it is a pure temperature radiation.

Electric Heating.

The limit of electric heating is clearly purely financial. To convert heat into other energy with a very small efficiency and to send it out by expensive cables and then to degrade the energy down to heat again is obviously much dearer than burning coal or gas direct. But in many domestic cases, the convenience is so great that the limit is not so low as might be thought, and electric heating for cooking and other domestic uses may develop considerably. The electric arc and incandescent lamps are essentially cases of electric heating. By far the most important use of electric heating is the furnace. Here the temperature available is only limited by the volatilisation of the electrodes, and this enables us to get temperatures otherwise unavailable, so that we can get chemical actions which are impossible at lower temperatures, either because they are endothermic or because the materials do not come into chemical contact at ordinary temperatures. It is impossible to say what our limits are in the electrical furnace. Probably the temperature is limited by the volatilising of carbon. The products are not limited to endothermic compounds; the furnace is useful for the reduction of metals and phosphorus, and for melting glass and, it is hoped, silica for optical and laboratory purposes, and perhaps for cooking utensils and evaporating pans and crucibles in chemical engineering and metallurgy.

Railways.

It is almost absurd to begin to consider the limits of the use of electrical transmission on railways at this date. The future of electric railways, electric tramways and automobiles is rather a matter of vague conjecture and picturesque prophecy. Tubes are multiplying rapidly, and railways are putting down electric transmission on suburban lines in Europe and the States. On short lines with many stops, we have to contend with inefficiency at starting. On long lines, there is difficulty of transmission or cost of transformation and difficulties of collection. We are limited by the want of either a variable speed simple alternate-current motor or a simple variable speed-gear capable of transmitting a very large torque and packing into an engine. A recently developed scheme is the use of low-frequency alternating currents with laminated series-wound motors. This solves the difficulty, but at the expense of large idle current, induced pressure in short-circuited armature coils, large expensive and inefficient transformers, and the ordinary disadvantages of the series-motor on constant pressure. This plan is well worth serious study.

The collection of large currents at great speeds has long loomed as a limit. The published accounts of experiments at Zossen would lead us to suppose there is no trouble on this score. Still, it is a difficulty many engineers fear.

In electric tramways, there is no limit in sight. The power can be sent over any distance desired, and there seems to be no limit to the people who want to travel on electrical trams. The question of electrolysis is rather that of a limit to the duration of pipe companies' property. It is a very difficult question. Though the threatened effects of electrolysis have no doubt been exaggerated, it is at best a question of degree, and the ingenuity of engineers is continually reducing the chance of damage. It has recently been urged that frequent reversals of polarity of the system reduce the electrolysis very considerably.

Electrolysis.

This is a branch of industry in which it is very difficult to tell our limits. In electrolytic copper-refining, our limit is that of the copper wanted. Our electrolytic industries suffer mostly from the limits of intelligence of the investing public. It is assumed that we cannot do electrolysis in England because we have no water power. This is only an excuse for inactivity. As already explained, we can do just as well without water power. A blast furnace is much more valuable than a waterfall of similar power, because it is near coal and in an industrial district. Moreover, as already explained, the cost of electrical energy is a small portion of that of most electrolytic products. At first, electrolysis was to be applied to copper-refining. Then to caustic soda. The output of electrolytic caustic is really rather limited by the demand for bleach. What is urgently wanted is some other way of storing and carrying chlorine. Steel bottles and compression plant are an unsatisfactory solution. What are the limits in the way of electrolysing fused salt They are all incidental limits. The containing vessel is

difficulty. Sodium vapour attacks all silicates. Sodium distils near the temperature of fused salt. If not volatilised, it forms a conducting bridge from the kathode. It attacks iron, though slowly. Hot porcelain and earthenware conduct electrolytically—as, by the way, the maker of electric frying-pans knows—hot chlorine attacks metals, even when dry, and hot carbon cannot be exposed to the air. In addition, sodium and perhaps chlorine are soluble in hot salt, and traces of sulphate in the salt act as carriers. I could a tale unfold if I read out laboratory notes of sodium experiments on a fairly large scale. The difficulties are all incidental, though, and I have little doubt electrolytic sodium at a few pounds per ton will be in the market soon, and will affect profoundly many chemical and metallurgical industries.

In metallurgy, electrolytic solution processes are in use or on trial for the more valuable metals, such as copper and nickel. The reaction between chlorine and metallic sulphides at high temperatures brings the whole domain of sulphide ores under our sway. Thus a sulphide, say galena, is treated with chlorine, which gives off the sulphur as sulphur, which is condensed and sold, making chloride of lead. The silver is extracted by stirring with a little lead, and the fused salt is then electrolysed, yielding pure desilverised lead and chlorine. The process is thus self-contained, yielding sulphur, lead and silver. It is specially applicable to mixed refractory ores which are now nearly valueless and very plentiful, and contain much metal content, such as the mixed lead-zinc sulphides of America or Australia. These reactions have been proved on the large or ton scale, and there is no technical difficulty. Unfortunately, mine people are somewhat ignorant of electrical matters, and it is exceedingly difficult to get them to understand or appreciate a process like this, capable though it may be of paying good dividends on very large capitals indeed.

Our limit in electrolysis in this country is almost entirely human inertia. Commercial and financial people do not understand it, and fight shy of it. But our technical people are nearly as bad. The pure physicist, as a rule, takes no interest in electrolysis or physical chemistry, and thinks it belongs to the chemical classroom on the other side of the passage. The chemist thinks it is higher mathematics and will have none of it, the mathematician thinks it may be an exercise in differential equations; but they are all agreed that it is a sort of continental fungus which flourishes with no roots, and that it is beneath the attention of a scientific man to know enough about it to give a reason for the broad statement that it is all nonsense.

DUTY-FREE ALCOHOL FOR SCIENTIFIC PURPOSES.

TEACHERS of organic chemistry have often expressed the opinion that alcohol used for purposes of education and research should be relieved of the heavy duty levied upon it. Two years ago, attention was directed to the need for action in the matter, and at the Glasgow meeting of the British Association in 1901, a committee was appointed, with instructions to approach the Board of Inland Revenue, with the object of endeavouring to secure the removal of this tax upon scientific work. As the result, the following regulations have been issued by the Board and published in the daily Press:

Regulations for the Use of Duty-free Spirit at Universities, Colleges, &c.

(1) An application must be made by the governing body or their representatives, stating the situation of the particular university, college, or public institution for research or teaching, the number of the laboratories therein, the purpose or purposes to which the spirits are to be applied, the bulk quantity likely to be required in the course of a year, and, if it amounts to fifty gallons or upwards, the name or names of one or more sureties, or a guarantee society to join in a bond that the spirits will be used solely for the purpose requested and at the place specified.

(2) The spirits received at any one institution must only be used in the laboratories of that institution, and must not be distributed for use in the laboratories of any other institution, or used for any other purpose than those authorised.

(3) Only plain British spirits or unsweetened foreign spirits of not less strength than 50 degrees over proof (*i.e.* containing not less than 80 per cent. by weight of absolute alcohol) may be received duty free, and the differential duty must be paid on the foreign spirits.

(4) The spirits must be received under bond either from a distillery or from an Excise or Customs general warehouse and (except with special permission) in quantities of not less than nine bulk gallons at a time. They will be obtainable only on presentation of a requisition signed by the proper supervisor.

(5) On the arrival of the spirits at the institution, the proper Revenue officer should be informed, and the vessels, casks or packages containing them are not to be opened until he has taken an account of the spirits.

(6) The stock of spirits in each institution must be kept under lock in a special compartment under the control of a professor or some responsible officer of the university, college or institution.

(7) The spirits received by the responsible officer of the institution may be distributed by him undiluted to any of the laboratories on the same premises.

(8) No distribution of spirits may be made from the receiving laboratory to other laboratories which are not within the same premises.

(9) A stock book must be provided and kept at the receiving laboratory in which is to be entered on the debit side an account of the bulk and proof gallons of spirits received with the date of receipt, and on the credit side an account of the bulk and proof gallons distributed to other laboratories. A stock book must also be kept at each other laboratory, in which must be entered on the day of receipt an account of the bulk and proof gallons of spirits received from the receiving laboratory.

These books must be open at all times to the inspection of the Revenue officer, and he will be at liberty to make any extract from them which he may consider necessary.

(10) The quantity of spirits in stock at any one time must not exceed half the estimated quantity required in a year where that quantity amounts to twenty gallons or upwards.

(11) Any contravention of the regulations may involve the withdrawal of the Board's authority to use duty-free spirits.

(12) It must be understood that the Board of Inland Revenue reserve to themselves full discretion to withhold permission for the use of duty-free spirit in any case in which the circumstances may not seem to them to be such as to warrant the grant of it.

J. B. MEERS,
Secretary.

Inland Revenue, Somerset House, W.C., November 17.

NOTE.—"Proof Spirit" is defined by law to be such spirit as at the temperature of 51° Fahrenheit shall weigh $\frac{12}{13}$ths of an equal measure of distilled water.

Taking water at 51° Fahrenheit as unity, the specific gravity of "proof spirit" at 51° Fahrenheit is 0·92308. When such spirit is raised to the more usual temperature of 60° Fahrenheit, the specific gravity is 0·91984.

To calculate the quantity of spirits at proof in a given quantity of spirit over or under proof strength:—Multiply the quantity of spirit by the number of degrees of strength of the spirit, and divide the product by 100. The number of degrees of strength of any spirit is 100 *plus* the number of degrees overproof, or *minus* the number of degrees underproof.

EXAMPLE:—19·8 gallons of spirits at 64·5 overproof
$100 + 64{\cdot}5 = 164{\cdot}5$ proof strength.
$164{\cdot}5 \times 19{\cdot}8 \div 100 = 32{\cdot}571$
taken as 32·5 gallons at proof.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—In connection with the School of Geography, Mr. Mackinder will lecture weekly during Hilary term on the historical geography of Europe, Mr. Dickson will lecture on surveying and mapping and on the climatic regions of the globe; he will also give, in conjunction with Mr. Darbishire, practical instruction in military topography; Mr. Herbertson will lecture on the British Isles, the regional geography of continental Europe, and on types of land forms, mountains and coasts; Dr. Grundy will lecture on the historical topography of Greece, and Mr. Beazley on the period of the great discoveries, 1480–1650.

SIR WILLIAM COLLINS has accepted the invitation to stand as the Liberal candidate for London University at the ensuing Parliamentary by-election.

We learn from *Science* that at a recent meeting of the National Academy of Sciences, a grant of eight hundred dollars was made from the income of the J. Lawrence Smith bequest to Dr. O. C. Farrington, of the Field Columbian Museum, Chicago, to enable him to conduct certain investigations upon American meteorites.

Just as in this country there are gratifying signs that teachers in secondary schools are making earnest efforts to acquaint themselves with scientific methods of teaching the subjects of the school curriculum, so in France there is a movement in the same direction. We learn from the *Révue générale des Sciences* that M. Liard, vice-rector of the Académie de Paris, is organising conferences of teachers in secondary schools at which the chief inspectors will explain to French schoolmasters the objects it is desired they shall have in view in their teaching. The first conference was confined to teachers of modern languages and the second was devoted to a consideration of the teaching of physical and natural science.

Another instance of the large scale on which provision is made for every grade of education in America is afforded by the post-graduate medical school that has recently been incorporated in the city of Washington. There are to be, we learn from the *Lancet*, 104 professorships established, as follows:—Six of preventive medicine, two of medical zoology, one of protective inoculation, serum-therapy and biochemistry, two of sanitary chemistry, eight of bacteriology, seven of pathology, fourteen of internal medicine and therapeutics, one of surgical anatomy, fourteen of surgery, six of military medicine and surgery, two of orthopædic surgery, nine of gynæcology, six of obstetrics, three of tropical diseases, four of diseases of children, two of mental and nervous diseases and electrotherapeutics, two of diseases of the stomach, eight of diseases of the eye, eight of diseases of the nose, throat and ear, four of special diseases and four of diseases of the skin.

The examination of the calendars of different University Colleges soon convinces the student of education that every class of society in the city where the college is located must come under its influence. In the case of the University College of Nottingham, for example, we find from the new calendar that for the twenty-second session of the college there are, in addition to lectures for preparing to graduate in the various university faculties, classes for artisans engaged in the engineering, building, and lace and hosiery trades. Students of the same college may be studying subjects so far removed as Greek and plumbing, Anglo-Saxon and pattern-making. While one student is training to become a schoolmaster and is attending lectures on psychology and pedagogics, another hopes to develop into an electrical engineer, and spends his time at electrical measurements in the physical laboratory. In such an institution, it should be impossible for a student to obtain other than a broad, catholic way of regarding the various branches of human knowledge.

It is a pertinent question whether we as a nation are incapable of looking ahead or whether we are too apathetic to provide for future contingencies. On all sides, warning voices proclaim the deficiencies in our educational system, lack of enterprise and antiquated methods. Prof. Bower availed himself of the opportunity afforded when he was delivering his inaugural address before the North British branch of the Pharmaceutical Society to point out how one practical side of botany, the study of vegetable economics, is ignored in this country at the present time. What is required is a well-equipped staff, including specialists in botany, physics, chemistry and physiology, to provide training for students, to institute research and furnish expert advice. Neither at Kew, which, as Prof. Bayley Balfour later expressed it, acts as the clearing-house for the Empire, nor elsewhere is such a staff to be found. The study of vegetable economics might, in Prof. Bower's opinion, be advantageously pursued in commercial centres such as Glasgow, Liverpool and Belfast, and he has laid before the authorities of his University the desirability of appointing a special lecturer in this subject.

On December 3, a conference on "Nature-study" was held with special reference to the development of the work of Stepney Borough Museum with the schools. Mr. J. H. Wylie presided over the meeting, which was held in the Art Gallery, and Canon Barnett, in welcoming the audience, brought forward a suggestion that the winter garden of the People's Palace should be made into a Nature-study centre. Mr. A. D. Hall gave a general address and offered no explanation of the meaning of Nature-study, saying that as most of his audience were teachers that difficulty was removed. He urged that living things should be studied, not collections of dead things in boxes, and suggested the growing of food plants in East-end schools. Bean seedlings, he said, could be measured by the children, who could then make curves illustrating the growth on squared paper. His only allusion to the Museum was in connection with a supposed annual outing of the children, and he suggested that the journey then undertaken might be illustrated in the institution. Prof. Farmer alluded to the help as regards material to be obtained from the Chelsea Physic Garden. The Rev. Claude Hinscliff stated that the object of the conference had been lost sight of, and showed the necessity of opening the eyes of the East-ender by means of the Museum to what he might see when he did go into the country. Mr. F. C. Mills, the chairman of the Museum committee, expressed his pleasure as regards the interest taken in the conference, in spite of the fact that its purpose had been unfulfilled. The School Board inspector for the district alluded to work such as that suggested by Mr. Hall and of an elementary biological nature having been carried on for years at the schools in which he was interested. Mr. Wilfred Mark Webb urged the teachers not to introduce formal and systematic lessons, and Miss Kate Hall, the curator of the Museum, who had organised the conference, spoke of her intentions and requirements.

SOCIETIES AND ACADEMIES.

London.

Royal Society, November 27.—"Descending Intrinsic Spinal Tracts in the Mammalian Cord." By C. S. Sherrington, M.A., M.D., F.R.S., and E. E. Laslett, M.D.Vict.

Experiments inquiring into the existence of spinal paths connecting the activity of segments situate nearer the head with segments lying further from the head.

The method adopted may be termed the method of "*successive degeneration.*" It consists in producing two or more successive degenerations with allowance of a considerable interval of time between them. In the piece of cord to be examined, a first degeneration is allowed time enough to remove all the tracts descending from sources other than those the immediate object of inquiry. When the time is complete, the cord is left, as it were, like a cleaned slate, on which once more a new degeneration can be written without fear of confusion with a previous one. The cord is then ready for receiving the lesion which shall cause degeneration of the particular tracts the existence of which is suspected. After a period suitable for the full development of the new degeneration, the cord is treated histologically by the Marchi method, and the microscopical examination proceeded to.

Results.

The spinal segments examined as sources of aborally-running fibre-systems have been posterior cervical, anterior thoracic, mid thoracic, posterior thoracic and anterior lumbar. From all these regions, the experiments demonstrate that copious aborally-running fibre-systems spring.

Speaking generally, of the fibres composing the aborally-running systems springing from the grey matter of the spinal segments examined, there may be distinguished two sets. For physiological description, it is in some ways convenient to regard the length of the spinal cord as divisible into regions; thus, a brachial for the fore limb, a thoracic for the trunk, a crural for the hind limb, a pelvic for pelvic organs, a caudal for the tail, and so on. A reflex initiated *viâ* an afferent path of one such spinal region may evoke its peripheral effect by efferent paths of a spinal region other than that to which the original entrant path belongs. Such a reflex has in a former paper by one of us [1] been termed a "long" spinal reflex, in contradistinction to reflexes the centripetal and centrifugal paths of which both belong to one and the same spinal region. The latter reflex it was proposed to term "short." [2] Analogously, in the aborally-running fibre-systems of the spinal segments examined, by our experiments fibres of two categories are found, one a set passing beyond the limits of the spinal region in which they arise, the other not passing beyond those

[1] C. S. Sherrington, "Croonian Lecture," *Phil. Trans.*, 1897.
[2] *Ibid.*

limits. The former we would term "long spinal," the latter "short spinal" fibres. In each of these main categories, there can be distinguished fibres of various intermediate length.

Again, the fibres of each of the above two categories may be classified into two sets or tracts, according to their topography relatively to the cross-section of the cord. Fibres of both of the above categories are situate both in the lateral columns and in the ventral columns of the cord. It is useful, at least for descriptive purposes, to indicate this by terminology. We thus recognise in the aborally-running intrinsic spinal fibre systems the following sets or tracts:—(α) *Ventral short fibres*, (β) *Ventral long fibres*, (γ) *lateral short fibres*, (δ) *lateral long fibres*. It must be added that the distinction into lateral and ventral is somewhat artificial, as there exists often, especially in the case of the "short" fibres, no distinct gap between the ventral and lateral fields of distribution of the fibres in the transverse area of the cord.

The paper concludes with an analysis of evidence as to decussation of the long and short fibres.

December 11.—"Quaternions and Projective Geometry." By Prof. Charles J. Joly, F.T.C.D., Royal Astronomer of Ireland. Communicated by Sir Robert S. Ball, F.R.S.

The object of this paper is to include projective geometry within the scope of quaternions.

Chemical Society, December 4.—Dr. W. H. Perkin, F.R.S., vice-president, in the chair.—The following papers were read:—The specific heats of liquids, by Mr. H. Crompton. When heat is applied to an unassociated liquid, there is an increase in molecular kinetic energy, internal work is done within each molecule, intermolecular attraction is diminished and a small amount of external work is done. The first two factors together make up the specific heat at constant volume. The evaluation of the diminution of intermolecular attraction is made by the author on the assumption that the total attraction is equal to the difference between the latent heat of vaporisation and the heat evolved when the vapour is compressed to the volume it would occupy as a liquid but without undergoing this change of state. Assuming that this attraction is zero at the critical point and increases regularly with decrease of temperature, its change with temperature is given by the expression $(L - RT \log V/v)/(T_k - T)$, where L is the latent heat, T_k and T the absolute critical temperature and absolute temperature respectively, V and v the volumes of the vapour and liquid respectively. Neglecting the fourth factor, viz., the external work done, the author shows that the molecular heats of various liquids for which the foregoing data are available agree fairly well with those calculated by this method.—The constitution of enolic benzoylcamphor, by Dr. M. O. Forster. It is shown that this substance is probably phenylhydroxymethylenecamphor from a consideration of the derivatives and decomposition products obtained from it.—Isomeric benzoyl derivatives from isonitrosocamphor, by Dr. M. O. Forster. Two isomerides have been obtained; one crystallises in yellow prisms and melts at 105°; the other is colourless, melts at 136° and does not give isonitrosocamphor on hydrolysis.—Action of phosphorus haloids on dihydroresorcins, by Drs. Crossley and Le Sueur.—The absorption spectra of metallic nitrates, ii., by Prof. Hartley. The positions of the characteristic absorption bands depend upon the molecular weights of the salts in solution. The characters of the spectra observed are equally well explained by the assumption that *partial* ionic or *partial* hydrolytic dissociation occurs on solution.—The constitution of the products of nitration of *m*-acetoluidide, by Dr. J. B. Cohen and H. D. Dakin.—The action of metallic thiocyanates upon carbonyl chloride, by Dr. A. E. Dixon. A description of the substituted thiocarbimides obtained.

Entomological Society, November 19.—The Rev. Canon Fowler, president, in the chair.—Dr. Sharp, F.R.S., exhibited the egg-cases made by a beetle of the genus Aspidomorpha (*A. puncticosta*), and stated that they had been sent to him by Mr. F. Muir, of Durban, Natal, where the beetle and the egg-cases are common.—Dr. Norman H. Joy exhibited a well-marked aberration of a female *Lycaena icarus* striped black on the underside in the place of the usual ocellations; a gynandromorphous specimen of the same species; an aberration of a male *Lycaena bellargus*, similarly striped on the underside; a specimen of *Everes argiades* taken in 1885 at Bournemouth; and specimens of *Apatura iris* from the neighbourhood of Reading, taken from what appeared to be the throne of the ruling "Emperor" of the wood. Whenever another iris came by, the one on the "throne" attacked it, and after a fight, in which one would eventually pursue the other out of sight, the victor returned to the perch. If this was captured, the next *iris* coming along would take possession, and so on.—Mr. Claude Morley exhibited a specimen of *Diastictus vulneratus*, Sturm., new to Great Britain, and a rare blue form of *Miratora vitellinae* from Tuddenham Fen.—Mr. G. C. Champion exhibited specimens of *Nanophyges duricuri*, Lucas, a beetle from Central Spain, with drawings of the larva, pupa and perfect insect.—Prof. E. B. Poulton, F.R.S., stated that Mr. A. H. Church, of Jesus College, Oxford, had observed the larvæ of a species of Cucullia (probably *C. verbasci*), feeding upon *Buddleia globosa* which was growing against a wall in the Oxford Botanical Gardens. It is possible that the eggs were laid upon the Buddleia because of the very rough general resemblance in certain respects between its leaves and those of Verbascum. Mr. R. McLachlan, F.R.S., mentioned the case of *Mamestra persicariae*, at Lewisham, choosing *Anemone japonica*. He had offered them fern and elder (which is reputed a favourite food), but the larvæ refused everything except the original anemone. Mr. Goss said that larvæ of *Choerocampa elpenor*, taken at Weybridge from a species of American balsam, afterwards refused willow herb, the usual food-plant of the species. Prof. Poulton read a communication from Mr. G. F. Leigh relating to the enemies of Lepidoptera in Natal. The very common grey South African rat seems to be particularly fond of almost any pupæ, and will gnaw through thick wooden boxes to get at them. They affect especially *Choerocampa eson* and *C. nerii*. Even more remarkable than their keenness in hunting pupæ is the way in which they capture moths on the wing when feeding. Whilst flying at dusk, a rat would leap from the roof right on to their food-plant, and more often than not the moth selected for attack was captured. Bats are also very destructive of South African insect-life.

Ray Society, December 11.—Council Meeting.—Mr. John Hopkinson, treasurer, in the chair.—A vote of condolence with the widow and family of the late secretary of the Society, the Rev. Dr. Wiltshire, was passed, and in his place Mr. Hopkinson was elected secretary. The question of the appointment of treasurer was not finally decided.

MANCHESTER.

Literary and Philosophical Society, December 2.—Mr. Charles Bailey, president, in the chair.—Mr. C. L. Barnes showed a number of experiments depending on Hawksbee's law, viz., that the pressure on the walls of a tube containing a fluid is less when the fluid is in motion than when it is at rest. Several of these are well known, *e.g.*, the apparent attraction which results when a current of air, radial or other, passes between two parallel discs, and the suspension of a ball on a jet of air or water. Other illustrations of the principle are that it is impossible to blow a celluloid ball, or even an inflated toy balloon, out of a funnel held in the ordinary upright position, though, if the funnel be reversed, the ball or balloon can be supported without difficulty. Also, if a couple of celluloid balls are placed on a kind of railway made by fastening two rods to one another, they cannot be separated by blowing between them. The experiment of forcing a celluloid ball out of a tall glass cylinder by blowing downwards upon it was also performed, as were also several others of a similar character.—Mr. Frank Southern exhibited and described a Japanese magic mirror, and Dr. C. H. Lees showed a small piece of apparatus used in the determination of the thermal conductivities of solids over wide ranges of temperature. It consists in principle of a differential hydrogen thermometer, one bulb of which is heated by an electric current either in a flat strip of metal wound round it or passing through the material of the bulb itself.

DUBLIN.

Royal Dublin Society, November 18.—Prof. D. J. Cunningham, F.R.S., in the chair.—Prof. T. Johnson read a paper on *Phellomyces sclerotiophorus*, Frank, a fungus of unknown affinities which causes a form of scab in potato-tubers and, in extreme cases, a dry rot. The author first observed the fungus in several potato varieties, grown in the west and other parts of Ireland, in the autumn of 1901.—Phellomyces causes the formation of discoloured patches in the skin of the

tuber, in the midst of which are generally present the minute sclerotia, 0·1 mm. in diameter, just recognisable, in washed tubers, with the naked eye. In mild attacks, the fungus simply makes the tuber unsightly; in more severe cases, it strips off layer after layer of the protecting skin of the tuber, and may ultimately penetrate through the skin into the flesh of the tuber, killing the protoplasm, sending the mycelial hyphæ between and through the cells, and boring into the starch grains. Both in appearance and action, Phellomyces is readily distinguishable from Rhizoctonia, an extremely common cause of scab and rot in potatoes. Phellomyces can pass from seed tubers to the resulting crop, and is communicable from infected ground to healthy tubers grown in it. The author found soaking the diseased tubers in 0·8 per cent. solution of formalin for 1½ hours destroyed the fungus, untreated diseased tubers giving, under otherwise similar conditions, a diseased crop. Three varieties imported from France, planted in Connemara, gave crops showing *Sclerotinia sclerotiorum* and *Phellomyces sclerotiophorus*, both unknown in France on the potato up to the present time. Frank first saw the fungus, in various parts of Germany, in 1894, and again in succeeding years. The author said he had nothing to add to the account given by Frank of its very imperfectly known life-history.—Mr. Leonard Murphy read a paper on a new method of determining the amount of liquid in distant and inaccessible tanks, &c.—Mr. G. H. Carpenter exhibited lantern slides of insects (Collembola) taken in Mitchelstown and Dunmore caves in the south of Ireland, pointing out that while some of the species seemed to be confined to such localities and to represent special modifications for life in caves, others were identical with insects found in the upper world with a discontinuous range, and must be regarded as the survivors of very old races.

EDINBURGH.

Royal Society, November 3.—The Hon. Lord M'Laren, vice-president, in the chair.—The chairman in his opening remarks made special reference to the publication of the Ben Nevis observations, the first volume of which had just been issued. Half the expense of these publications, which would fill three volumes of the *Transactions*, was being borne by the Royal Society of London. Another matter of special interest was the systematic bathymetrical survey of the Scottish lakes which had been organised by Sir John Murray and Mr. Laurence Pullar. During the seven months beginning March last, they had surveyed 153 lochs and taken nearly 24,000 soundings. The greatest depth observed was in Loch Morar, 1009 feet, which exceeds by several hundred feet the depth recorded in any other lake in the British Islands. In addition to the routine work of taking soundings and determining heights, observations of temperature and of "seiches" and collections of plankton and bottom deposits were made by the staff. The results were now being prepared for publication in Edinburgh, and preliminary papers dealing with the work would from time to time be laid before the Society.—Sir William Turner communicated a paper entitled "Contributions to the Craniology of the People of Scotland." The material had been collecting for many years in his hand, and in this first paper he gave the detailed results of the measurement of nearly 200 skulls obtained from all parts of Scotland. Of these, 28 per cent. were dolichocephalic, 20 per cent. brachycephalic, and 52 per cent. belonged to the intermediate group. As regards their distribution, the brachycephalic type was characteristic of Fife, the Lothians, the eastern counties between the Tay and the Moray Firth, and Shetland; whilst the dolichocephalic type was most prevalent in Renfrewshire, Wigtonshire, Caithness and the Highlands. A very marked percentage of the brachycephalic skulls had distinct frontal sutures, a very unusual feature in adult skulls. This indicated growth in breadth during adult life. The skulls were capacious and somewhat above the average for western Europe. As regards the facial characters, the orbits were wide and circular and the noses long and narrow. The discussion of the ethnographical bearing of the facts was reserved for a second paper.—In a paper on the electrical conductivities and relative densities of certain samples of sea-water, Mr. J. J. Manley described some novelties of method in the accurate measurement of these quantities. The results were negative, there being no discoverable relation between the conductivities and densities.—Two papers by Dr. Thomas Muir on generating functions of certain determinants were also presented.

November 17.—The Rev. Prof. Duns in the chair.—Dr. W. G. Aitchison Robertson read a paper on the local distribution of cancer in Scotland. In collecting his material, he had visited many of the larger institutions and infirmaries throughout Scotland, and from careful inspection of the registers had, as far as possible, allocated the various cases to their proper counties. In this respect, he believed that his statistics were more accurate than those derived directly from the reports of the Registrar-General, for it was quite evident that many of the cases recorded as having occurred in the larger towns really belonged to neighbouring or even remote country districts. His corrections made important changes in the chart of distribution. Thus, when corrected for the presence of strangers, the cancer mortality for the city of Edinburgh fell from 5·15 per cent. (as it appeared to be from the Registrar-General's returns) to 4·13 per cent., which is practically the normal for the whole of Scotland. On the other hand, by the same correction the cancer mortality for the county of Edinburgh increased to nearly 5 per cent. On the whole, the mainland rural districts and smaller towns had a higher cancer mortality than the large towns and cities. In the county of Nairn, the mortality was 9·73 per cent. In the outer Hebrides, the mortality was distinctly below the normal for Scotland. The statistics showed many curious features, and it was utterly impossible to connect the distribution with climatic or geologic conditions, or with race or food supply. That the towns were healthier than the rural districts seemed to dispose of several of the ordinary theories as to the undoubted increase of the disease within the last half-century. This could be regarded as only a first effort to get at information regarding local distribution of cancer, and Dr. Robertson urged upon the medical profession in Scotland the importance of a combined investigation of the causal relations of this dread disease.—Mr. J. Ross communicated a short note on the trisection of an angle, and a paper by Dr. Thomas Muir on pure periodic continued fractions was also read.

PARIS.

Academy of Sciences, December 8.—M. Bouquet de la Grye in the chair.—The president announced to the Academy the death of two members, M. Dehérain, member of the section of Rural Economy, and M. Hautefeuille, member of the section of Mineralogy.—On the transformation of the diamond into black carbon during its oxidation, and on the isomeric changes of simple bodies during decompositions and combinations, by M. Berthelot. Some remarks on work recently published by M. Moissan.—On the irreducibility of the equation $y'' = 6y^2 + x$, by M. Paul Painlevé.—On the quantity of free hydrogen in the air and the density of atmospheric nitrogen, by M. Armand Gautier. Four years ago, the author published work proving the existence of free hydrogen and methane in the air, and estimated their quantity. The proportion of hydrogen then found has been questioned by Lord Rayleigh, and M. A. Leduc has recently adduced other evidence in confirmation of Lord Rayleigh's objections. It is shown that the exact concordance between the percentage of oxygen by weight found by M. Leduc and the value calculated from the densities of the gases is accidental, and that the results are quite consistent with the presence of the amounts of hydrogen and methane found by the author.—On the development of the Peripatidæ of South Africa, by M. L. Bouvier.—On some Hæmogregarians of Ophidians, by M. A. Laveran.—The internal action of copper sulphate in the resistance of the potato to *Phytophthora infestans*, by M. Emile Laurent. The experiments described led to the conclusion that potato tubers should be immunised against this fungus by dipping them for a certain time in a solution of copper sulphate, but on actual trial it was found that potatoes so treated and then purposely infected with the Phytophthora were attacked as vigorously by the parasite as the untreated tubers.—Observations of the new comet Giacobini (*d* 1902), made at the Observatory of Paris, by MM. G. Bigourdan, G. Fayet and P. Salst. On December 6, the comet was a nebulosity of magnitude 13·2, diffuse, vaguely rounded and of 30" diameter.—Provisional elements of the Giacobini comet, by M. G. Fayet.—On the properties of the plane from the point of view of the *Analysis situs*, by M. Combebiac.—On a summatory form in the theory of functions of two variables, by M. Martin Krause.—

On a dark chamber for three-colour photography, by M. Prieur. The problem to be solved was to devise a mechanism which, on closing the shutter, would remove the exposed plate and at the same time replace it by the succeeding plate, placing the latter accurately in the focus of the objective. This problem has been satisfactorily solved.—On bipolar electrodes with a soluble anode, by MM. André Brochet and C. L. Barillet. In an electrolytic cell containing a solution of copper sulphate, the interposition of an insulated copper plate gives results very similar to those previously described with a platinum plate. It was not found possible to predict the phenomenon in any given case.—On thallic chloride, by M. V. Thomas. The chloride $TlCl_3, 4H_2O$ can be dehydrated in a vacuum without any loss of chlorine. The properties of the anhydrous chloride are given.—On Gmelin's violet manganese metaphosphate, by M. Ph. Barbier.—Addition derivatives from cyclohexene, by M. L. Brunel.—On a dichlorhydrate and dibromhydrate of cadinene and on a dextrorotatory regenerated cadinene, by M. Emilien Grimal.—On the essence of vetiver, by MM. P. Genvresse and G. Langlois. This essence contains a sesquiterpene, a sesquiterpene alcohol, and an ester to which the odour is due.—On the excretion and variation of the kidney in carnivorous fowls of the second generation, by M. Frédéric Houssay.—The formation of chlorophyll in rarefied air and in rarefied oxygen, by M. Jean Friedel. In air expanded to one-sixth of the atmospheric pressure, the leaves of Phaseolus are almost entirely etiolated; in oxygen at the same pressure, the leaves are coloured as in ordinary air. It would thus appear that the relative pressure of the oxygen is the predominating factor, the total pressure having no sensible influence.—On some new fossil infusoria, by M. B. Renault.—On the immunisation of the lettuce against the fungus *Bremia Lactucae*, by M. E. Marchal. By treatment with solutions of copper sulphate of certain strength, it was found possible to prevent the growth of the parasite from interfering with the growth of the plant. The narrow margin, however, between the immunising dose of copper sulphate and that capable of acting injuriously on the lettuce plant renders the practical application of these results difficult.—Some mineralogical observations made on the products from the burning of St. Pierre, Martinique, by M. A. Lacroix.—On the Palæozoic earths of Oued Saoura and Gourara, by M. E. F. Gautier.—On economic appreciation and improvements due to cultivation, by M. E. Rabaté.—On the application of chemical manures to the cultivation of the vine in the calcareous earths of Charentes, by MM. J. M. Guillon and G. Gouirand.—On some exotic Graminaceæ employed in food, by M. Balland.—On some brilliant red sunsets observed at Athens during the months of October and November, 1902, by M. D. Eginitis.

New South Wales.

Linnean Society, October 29.—Mr. J. H. Maiden, president, in the chair.—On two remarkable Sporocysts occurring in *Mytilus latus*, on the coast of New Zealand, by Prof. W. A. Haswell, F.R.S.—(1) On *Eucalyptus polyanthemos*, Schauer; (2) on *E. bicolor*, A. Cunn, by Mr. J. H. Maiden. The author quotes the original descriptions of the species, cites their synonyms, discusses their affinities and gives an account of their range.—Contributions to a knowledge of the Australian flora, part iv., by Mr. R. T. Baker. A number of new localities for species are recorded, thus extending their known geographical range.—Notes on the botany of the interior of New South Wales, part vii., by Mr. R. H. Cambage. The conspicuous vegetation of the country between Forbes and Bathurst is described.—On the mammalian and reptilian vomerine bones, by Dr. R. Broom. The author shows that in the early stages of development the nasal capsules of the lizard and marsupial are essentially similar in structure and that in both a well-developed paraseptal cartilage runs by the base of the septum from the nasal floor cartilage in front to the hinder part of the capsule. He also shows that the so-called "vomer" in the lizard develops in connection with this cartilage; and as the dumbbell-shaped bone in Ornithorhynchus and the median bone of Miniopterus also develop as splints to the paraseptal cartilages (specialised as cartilages of Jacobson), he concludes that these mammalian bones are homologous with the so-called "vomers" of the lizard and are therefore really *prevomers*.

DIARY OF SOCIETIES.

THURSDAY, December 18.

Linnean Society, at 8.—Notes on Copepoda from the Faeroe Channel: Thos. Scott.—Amphipoda of the *Southern Cross* Antarctic Expedition; Alfred O. Walker.—The Deep-Sea Isopod *Anurus branchiatus*, Bedd.: Dr. H. J. Hansen.

Institution of Electrical Engineers, at 8.—Notes of Recent Electrical Designs: W. B. Esson.

FRIDAY, December 19.

Institution of Civil Engineers, at 8.—Electricity Supply from Double Current-Generators: P. R. Wray.

Institution of Mechanical Engineers, at 8.—Recent Practice in the Design, Construction and Operation of Raw Cane Sugar Factories in the Hawaiian Islands: J. N. S. Williams.

TUESDAY, December 23.

Institution of Civil Engineers, at 8.—*Paper to be further discussed*:—The Rupnarayan Bridge, Bengal-Nagpur Railway: S. Martin-Leake.—*Paper to be read*:—Electric Automobiles: H. F. Joel.

CONTENTS.

THURSDAY, DECEMBER 25, 1902.

AGRICULTURAL SCIENCE IN ITALY.

Chimica Agraria, Campestre e Silvano. Di Italo Giglioli. Pp. xviii + 877; with 31 figures in the text. (Naples: Marghieri, 1902.)

THIS book, the work of the well-known professor of agricultural chemistry in the College at Portici, was originally projected as a treatise on agricultural chemistry, to be followed by other volumes dealing with fermentation and animal chemistry. Written, as the author tells us, with many interruptions, between 1884 and the current year, it remains but a fragment of the original scheme, for it deals only with the relations of the plant to water and to solar light and heat—questions, indeed, of fundamental importance to the agriculture of a semi-arid country like Italy. With nearly 900 pages devoted to so small a section of the subject, it will easily be imagined how vast is the scale upon which the work was planned, and this arouses a question which struck us repeatedly during the perusal of the book. Given a treatise on a technical branch of science, like agricultural chemistry, how far should the author deem it his duty to enter into a complete discussion of whatever branch of the pure science he may require to use for the explanation of some technical problem? For example, we have in the book before us some ten pages, 628–638, given up to an acconnt of the nature of exothermic and endothermic chemical reactions. Now, though it is impossible to understand the problems presented by carbon assimilation under the action of light without possessing the conception of the transfer of energy accompanying a reaction and the reversibility of the change, we hold that the reader of a book like the present will have either reached already the required knowledge of pure chemistry or else must be introduced to the new idea in a much less academic fashion. In the main, a book of this type is written for the expert and should stick very close to its text, taking something more than the elements of the pure sciences for granted.

But it is precisely in this direction that Prof. Giglioli's weakness lies, with the result that the book is cumbered and inordinately expanded with irrelevant matter, interesting enough, but not really bearing upon the point. For example, all kinds of light waves and ethereal radiations doubtless possess some action upon the living plant, but as these effects are still practically unknown, it is surely superfluous to devote fifty pages to a purely text-book account of phosphorescence and kindred phenomena, including the incandescent properties of the rare earths in the Auer lamp, Crookes's tubes, radiant matter and kathode rays; nor, again, in another section, can we see the appropriateness of a discussion of the skin vision of animals or of Prof. Poulton's experiments on the influence of coloured lights upon the larvæ of *Pieris*.

This is the most unsatisfactory portion of the book, and we cannot help feeling that, in his desire to be exhaustive, Prof. Giglioli has discharged upon us pell-mell all the references he has accumulated, without considering how far they have yet been made to bear upon his subject. It is true that the man of science who wants to go beneath the surface of things must carry in his mind all sorts of cognate facts and investigations, in the hope that some day they may supply a missing link in his own work, but he should not present the public with this raw material.

The earlier sections of the book, dealing with the relations of the plant to water, are less academic, and contain many interesting references to the author's own experiences of agriculture under the hot suns and small precipitation of Italy. He discusses at some length the development of the root, and refers to this cause the increased power of resisting drought which certain manures, particularly nitrate of soda, give to the crop. In this section, Prof. Giglioli draws freely on the results of the Rothamsted experiments, particularly on Lawes and Gilbert's paper upon the drought of 1870 and its effect upon the variously manured grass plots. This question of the action of manures upon root development is worthy of more study than it has hitherto received, for it seems to afford a clue to the explanation of the greater ease with which a plant manured with nitrate of soda will in some cases obtain its other mineral food from the soil, as compared with one receiving the same amount of nitrogen in the form of ammonium salts.

The earlier chapters of the book have not been brought so closely up to date as the later pages; in the account of the amount of water transpired by plants, we have Lawes and Gilbert's figures, but not the later work of Hellriegel, Wollny, and King of Wisconsin, and again, in the discussion of the value of tillage in conserving soil moisture, no mention is made of the valuable observations which have been accumulated in America on this point.

The reader who is interested in the effect of climate upon crop production will find that Prof. Giglioli deals repeatedly with this most intricate problem. The alteration by climate of English varieties of wheat introduced into Italy is discussed on pp. 187 and 379, a subject of interest at the present time, when efforts are being made to get into English wheats something of the "strong" character of those imported from more arid countries, and again, on p. 189, we have a correlation of the hay crops grown at Rothamsted under various systems of manuring with the rainfall of the months of April, May and June.

On p. 100, we have a reference to Frank's discovery of mycorhiza, but we have no account of the weighty generalisations contained in the later papers of Frank and of Stahl, which have shown how interesting and widespread a variant of the general course of nutrition is presented by plants with mycorhiza.

The special value of the book lies in its enthusiasm and breadth of view; we feel we are dealing, not only with a specialist, but also with one who possesses a many-sided knowledge and experience. To an Englishman, it is pleasant to see how references to English work abound; particularly it is clear that Prof. Giglioli has kept himself familiar with the experiments at Rothamsted, where so much of the pioneer work in agricultural science has been done. Prof. Giglioli contrasts Italy unfavourably in the matter of agricultural experiments, but will the English work play so large a part in any treatise of a foreign professor fifty years hence? Rothamsted stands where

it did, the monument of two great men's work, but unconnected with any organisation, either official or educational; other countries have been only too anxious to foster and develop any living starting point they could find. A. D. H.

A HIMALAYAN LOCAL FLORA.

Flora Simlensis: a Handbook of the Flowering Plants of Simla and the Neighbourhood. By the late Colonel Sir H. Collett, K.C.B., F.L.S. Pp. lxviii + 652. (Calcutta and Simla: Thacker, Spink and Co.; London: W. Thacker and Co., 1902.)

WHEN, in 1897, Sir Joseph Hooker wrote his preface to the final volume of the "Flora of British India," he gave it as one of the chief uses of his great work that it would "facilitate the compilation of local Indian floras." We believe that since that book began to issue, the handbook before us is the first general local flora that has been prepared for India, though various floras for *forest* purposes only have already appeared. Other general floras, for what are wider areas, are in course of preparation for Bengal, Bombay and the Upper Gangetic Plain; but although these floras will apply to whole provinces, or at any rate to areas as large as provinces, they will, none of them, cover so wide a vertical range, for the late Sir H. Collett's handbook practically treats of plants growing at all altitudes, from the Himalayan valleys only a little raised above sea-level to elevations of 12,000 and even of 16,000 feet. The area taken up is not one of exact geographical limits, but, as the author has said:—

"I have assigned no strictly defined limits to the 'Flora,' believing that this would answer the requirements of students better than if I were to confine it, for instance, to the territorial limits of the Simla Municipality or any other arbitrarily fixed boundaries."

It seems, however, to include every plant which a Simla botanist is likely to meet with in his rambles, and we feel sure that the book will be much appreciated, though we cannot avoid a feeling of great regret that its author has not lived to enjoy the pleasure he looked forward to of knowing that he had done something to help those who are already students of his favourite science, and perhaps to induce more of those Indian officers who want a pursuit to occupy their leisure time, to follow in his footsteps and study the plants of the forests, glens and slopes of the Simla mountains.

It has not been an uncommon thing at Simla to hear the wish expressed that someone would publish a handbook of a not too difficult scientific character, giving the names and descriptions of the chief plants; and, as the author has explained in his preface, it was with the desire of supplying this want that he commenced his work. A careful examination of the book shows that his efforts have been successful. The descriptions are concise and couched in the simplest language; the analyses lead easily to the genus and species required; while the excellent pen and ink drawings prepared by Miss M. Smith, of Kew, will be a great additional help to those who consult the work. These drawings have been judiciously selected, to illustrate, not only the chief genera and species, but also the most common and conspicuous plants to be met with in Simla and its neighbourhood.

In addition to the characters of the natural orders, genera and species, and to analyses and an account of the geographical distribution of the plants, many useful notes are given which are sure to be of interest. As a sample may be cited the brief account of the method of fertilisation of Roscoea, a genus of gingers with purple flowers, where the mechanism by which the anthers are caused to shed their pollen on the backs of the insects which visit them is shown to be similar to that of the quite different genus Salvia in Labiatæ. The derivations of the generic names have been duly explained, and wherever it has seemed of interest, reference has been made to such books as Darwin's "Origin of Species," Fritz Müller's "Fertilisation of Flowers" and Kerner's "Natural History of Plants." It is clear that Sir Henry Collett took the greatest pains to make his book as useful as possible, and it is well that the pioneer of Indian local floras will be such an excellent model for future work of the kind. To the author, as every page of his book shows, his work must indeed have been a labour of love. It will be useful to residents and visitors, not only in Simla, but in the other hill resorts in the Punjab, while even in the more easterly ones—Chakrata, Mussooree, Naini-Tál—where the flora is richer, the book will be of considerable help to those interested in plants.

Besides Sir H. Collett's own preface, the descriptive portion of the work is preceded by an "In Memoriam" notice of the author by Sir W. T. Thiselton-Dyer, K.C.M.G., F.R.S., the Director of Kew, and by an "Introduction" by Mr. W. B. Hemsley, F.R.S., the curator of the herbarium at the Royal Gardens. In his notice, Sir W. T. Thiselton-Dyer gives a brief account of the life of the author, who, during a long and distinguished career as a soldier, studied science, and especially botany, in his leisure moments, and after his retirement in 1893 commenced the present work, which he only just lived to complete. Sir William finishes his notice by saying:—

"No one who has ever come to work among us at Kew has more completely won the affectionate regard of everyone with whom he has come in contact."

In his "Introduction," Mr. Hemsley gives a brief account of the geography of Simla, of its vegetation and of the chief botanists whose collections have been utilised in the preparation of the handbook. Some idea of the extent of the flora of the small Himalayan area to which it refers is obtainable from the fact that the handbook describes no less than 1326 species belonging to 639 genera and 113 natural orders.

We may conclude this brief account of a noteworthy botanical handbook with the following extract from the address of the president at the anniversary meeting of the Linnean Society on May 24 last:—

"In Sir Henry Collett we lose an accomplished botanist who was also a gallant soldier and a capable administrator, a combination of qualities that seems to be peculiarly British. It would not be easy to estimate how much this Society, and other kindred societies, owe to the public services, and more particularly the Indian, for the invaluable recruits whom we continually draw from their ranks."

We can hope that the "Flora Simlensis" will prove as enduring a memorial of its author as the record of his achievements, military and administrative, is likely to be in the history of the Indian Empire. J. S. G.

OSTWALD'S INORGANIC CHEMISTRY.

The Principles of Inorganic Chemistry. By Wilhelm Ostwald. Translated by Alexander Findlay. Pp. xxvii + 785. (London: Macmillan and Co., Ltd.) Price 18*s*. net.

VIEWS differ regarding the best method of presenting the facts and theories of chemistry to a beginner. Prof. Ostwald takes the view that "if the present-day chemistry makes greater demands on the power of rational thinking, it also renders the purely memory work of mastering the subject considerably more easy for the student. The growth of the scientific interpretation and elucidation of the separate facts of chemistry facilitates in the highest degree the impression of them on the mind and their application, and at the same time affords an incomparably greater intellectual enjoyment than the study of the older, essentially descriptive, chemistry could offer." Acting on this opinion, Ostwald has introduced physical theories, applicable to chemical facts, "in his stride," as it were. Beginning with some simple metaphysical statements, he develops the fundamental laws of classification and treats of homogeneous substances, mixtures and solutions; he next proceeds to consider the law of the conservation of weight and mass, and of work and energy, treating incidentally of the units in which these magnitudes are measured. The next chapter is devoted to "combustion," the existence of oxygen and the constancy of proportions; and the next to a rapid survey of the elements and their properties. The subsequent treatment is, in a restricted sense, systematic; the remaining chapters treat of oxygen, ozone, hydrogen, water, hydrogen peroxide, chlorine and hydrochloric acid, oxides of chlorine; bromine, iodine and fluorine, sulphur and its compounds, and, in short, the elements generally termed non-metals and their compounds; the metals and their salts complete the list.

But the discursive nature of treating the subject may be gauged by the amount of space—92 pages—devoted to the consideration of oxygen, hydrogen and water. Under the heading "Oxygen," not merely are the preparation and properties of the element considered, but also velocity of combustion, the influence of temperature on that rate, Boyle's and Gay-Lussac's laws, the temperature scales, degrees of freedom of a gas, the construction of curves, the liquefaction of gases, the solubility of gases, and ozone; the condition of allotropy is also shortly discussed. Under "Hydrogen" come methods of drying gases, molecular weights (here termed "molar" weights), the compressibility of gases at high pressures, diffusion, the law of partial pressures, the law of effusion of gases and spectrum analysis; also, *à propos* of the combustion of hydrogen, the law of mass action, chemical equilibrium and the influence of solid substances thereon; and lastly, catalysis, introduced by the catalytic action of platinum in causing combination between oxygen and hydrogen. Under the heading "Water," we find the law of continuity, graphic interpolation, coefficient of expansion, degrees of freedom of liquids, supercooling, heats of fusion, heat-units, vapour-pressures, heats of vaporisation, supercooled vapours, phases of water, ice and steam, and the triple point; next water as a solvent, and the relations between lowering of freezing point and depression of vapour pressure caused by salts; volume relation of gases, "combining" weights, symbols and formulæ, equations, and the atomic and molecular hypotheses.

Now Prof. Ostwald's style is excellent, and full justice is done to it by Dr. Findlay's translation; hence the book is most readable and interesting; the theoretical disquisitions are most clearly stated and arranged in an orderly manner, each point being taken up when its turn has come, but the reviewer doubts whether a beginner would gain much from a perusal of the book. For a teacher who is already familiar with the facts of chemistry, innumerable hints are to be found, almost on every page. But after all, the young chemical student has to familiarise himself with the facts of chemistry, and gilding the pill, even with fine gold, is apt to interfere with its assimilation. For a man of advanced years, even though he be no chemist, who can appreciate the logical arrangement of the book, much enjoyment may be obtained from it; but from long experience of the powers of mind of junior students, the reviewer doubts whether more than two or three specially gifted individuals out of a large class would retain much in their memories.

Just as in learning a language it is absolutely necessary to acquire the common verbs, prepositions and adverbs by heart, and to have at least some idea of the syntax before analytically parsing the sentences, attending to every subtlety, so with chemistry. A large number of facts and their experimental demonstration must become familiar, and it is then time to build up laws on these facts.

However, as stated at the outset, there are many methods of presenting such facts; and if the young student has energy to follow two or three methods of presentment, he will be a gainer. It appears to the reviewer that it would be better to reserve this method of considering the subject until a year, or perhaps more, has been spent in the more usual course of study. The effect of reading such a book at that stage is sure to be most stimulating, and will enable the reader, not only to revise his knowledge, but to enrich it by many necessary additions.

It is unnecessary to mention that the work is entirely up to date, and that the translator, as an old pupil and friend of the author, has completely entered into the spirit of the matter; he has left no trace of its German origin in the excellent English of which he is a master.

W. R.

A NEW THEORY OF THE UNIVERSE.

On an Inversion of Ideas as to the Structure of the Universe. By Prof. Osborne Reynolds, F.R.S. Pp. 44. (Cambridge: University Press, 1902.) Price 1*s*. 6*d*. net.

THIS is a short description of a new theory of the universe which formed the subject of the Rede lecture last June. All such theories must satisfy two conditions. The structure must be dynamically possible, and the results deduced by dynamical reasoning from the

theory must correspond qualitatively and quantitatively to the phenomena of Nature. The analytical difficulties may be too great to deduce all the phenomena, but if any be contrary to experience, the theory, at least in its exact form, must go. It is only by inventing, discussing, comparing and remodelling as many theories as possible that we can hope to arrive at any knowledge of the constitution of matter or of the æther. This new and very original attempt is therefore to be welcomed. As a rule, authors of such theories are satisfied to show how many facts their theory explains, and how probable, therefore, it is that their theory corresponds to reality. Not so, however, Prof. Osborne Reynolds. He claims to have shown that "the research has revealed the prime cause of the physical properties of matter," and that

"there is one, and only one, conceivable purely mechanical system capable of accounting for the physical evidence as we know it in the universe."

That a theory coming from Prof. Reynolds will fulfil the first of our conditions goes without saying. But that it should be possible to give a proof that it *is* the representation of the actual structure of æther and matter is too astonishing to be received without scepticism. We await the publication of the full research.

It is not possible to criticise a complete theory on a short statement of its results—a statement which by its very nature must leave much vague and much unsaid. Sufficient idea, however, is given to cause us to look forward to the complete work, which is, we understand, to be published by the Pitt Press shortly. In brief, the æther is composed of equal rigid spherical grains (diam. = $1 \cdot 7 \times 10^{-12}$ times the wave-length of violet light) arranged in regular and closest order, and under great pressure. When strained, such a medium must expand—or show "dilatancy." The actions of the medium depend on this dilatancy. Matter is a defect of matter—a small deficiency of grains or a "negative inequality," causing, so to say, a certain looseness in the gearing of the grains where the deficiency exists and a consequent stress in the medium outside. These inequalities are permanent, and are propagated through the medium without a transference of the grains themselves. Matter is, in fact, a strain which is propagated through the medium—an idea which has occurred to others, notably Dr. Larmor in his electron theory, and to the late Mr. C. V. Burton, at the Ipswich meeting of the British Association in 1895. These strains attract one another according to the Newtonian law, may cohere but not coalesce. "Positive inequalities" (due to excess of grains), on the contrary, repel one another and so are dispersed. Electricity apparently consists of double inequalities, excess in one place and defect in another. The statement here appears rather vague, and it is difficult to understand the difference between electricity and two inequalities, one positive and one negative. The attraction is, however, enormously greater than that of gravitation. Apparently the theory gives no explanation of the fact that electricity never shows itself apart from matter, nor is any explanation offered of the electrodynamic action of one current on a conductor bearing another. A true theory must do this, and it is the crux of every theory yet produced.

In this granular medium, transverse and longitudinal waves are propagated. It would take 56 million years to reduce the energy of the transverse to one-eighth, while it would take only four one-millionths of a second to reduce that of the normal by the same amount, thus, the author says, "accounting for the absence of normal waves." This, however, is only a proof that such waves do not last. It is necessary to show that on reflection of light they are not formed, otherwise they will diminish the intensity of the reflected ray.

Many difficulties and objections suggest themselves during perusal which will doubtless be answered in the full paper. If Prof. Reynolds does in this what he promises in the *résumé*, he will go down to posterity with a greater fame than Newton. If, however, he does not succeed in convincing us that he has solved the problem of the mechanism of the physical universe, he may yet be congratulated on giving us what is evidently a beautiful, illuminative and extremely suggestive theory. He has opened to us, in any case, a new field of knowledge as well as helped to stimulate that scientific imagination which we are told it is our bounden duty to cultivate.

W. M. H.

OUR BOOK SHELF.

Report of the Yellow Fever Expedition to Pará of the Liverpool School of Tropical Medicine. By H. E. Durham. Pp. 79. (London: Published for the University Press of Liverpool by Longmans, Green and Co., 1902.) Price 7*s.* 6*d.*

THIS is the seventh memoir published by the Liverpool School of Tropical Medicine, and it is printed and got up in the same excellent style as its predecessors. It embodies the results of the Parà expedition of Messrs. Durham and Myers, and is written by the former, Dr. Myers having, as is well known, fallen a victim to the disease he was investigating, a circumstance which lends a melancholy interest to the report. When the expedition left this country, the remarkable and conclusive work of the United States Army Commission in Cuba under Major Reed in proving the conveyance of yellow fever by gnats was not known, but this problem, with many others awaiting solution as regards the disease, was present in the minds of the observers, as is seen in the preliminary report, which is here reprinted from the *British Medical Journal.* In the course of their work, they became acquainted with the results of the Americans, and a number of observations are chronicled in the report with regard to the gnat (*Stegomyia fasciata*) incriminated in Cuba. It was bred in captivity and studied in its native haunts, and much useful information gathered as to its habits—the most striking being its essentially urban habitat, and its custom of biting by day and not at night.

With regard to the actual microbe which is the cause of yellow fever, no sufficient proof is as yet forthcoming, but the observations of the expedition agree with those of Agramonte and others in absolving Sanarelli's *Bacillus icteroides* from any share in its ætiology. Attention is, however, already called in the interim report, an abstract of which is here reprinted, to a small, fine bacillus which the English observers found with considerable constancy in the intestines and in the viscera generally in fatal cases, and to which they were inclined, with due reserve, to ascribe a causal significance. It had previously been observed by Sternberg and others, but not with the constancy here recorded. A valuable series of observations on the condition of the lymphatic glands in yellow

fever and another series on the occurrence of peculiar proteid substances in the urine must also be noted.

Together with these positive results, there is necessarily included a mass of detail concerning results which proved negative. The writer has, further, added to his account of the experimental work performed a quantity of somewhat miscellaneous facts gathered in Parà and elsewhere on the subject of yellow fever and malaria, with a general account of the sanitary condition of the town. But when it is remembered that the work of the expedition was in great part crippled by the illness of both and the death of one of its members, we can but congratulate the survivor on the work which was accomplished, regretting that opportunities were not forthcoming for carrying it to a further stage of completeness. Yellow fever is a disease which has long been a puzzle to sanitary science, but appears at the present day to be on the verge of explanation. An immense step in advance has been made by the discovery of its transference by the gnat; the complete solution of the problem must be attained by further investigations on the lines of those embodied in this report, and carried out by skilled and unbiased investigators such as those sent out by the Liverpool School of Tropical Medicine.

Eyes Within. By Walter Earle, M.A. Pp. 155. (London: George Allen, 1902.) Price 5*s.*

THIS little volume of poems contains some good references to Nature and her handiwork. We are led to realise the ever-changing condition of the earth's surface, and phenomena of many kinds are dealt with. Thus:—

> "See where upon a world-old mountain face
> Some mighty glacier has left its trace,
> A few faint scratches, all that marks to-day
> Time's agonies along his primal way."

Allusions are also made to the great variety of changes always going on around us, and to the disturbing elements raging ceaselessly in the interior of the earth:—

> "Shrill crash of breaker plunging in the cave,
> The soughing wind, waves grinding on the shore,
> Weird wail and scream of bird, set evermore
> In fuller diapason stern and grave."
>
> . . . . .
>
> "Crack, rent and crush of overwhelming rock,
> Steam bursting into flood of liquid blaze,
> A world vibrating with each thunder-shock,
> Suns setting in a pall of wreckage-haze.

All through the book we are struck with the delicate and subtle way with which common and every-day occurrences are referred to. Birds, flowers, insects, all have their due.

The author shows the true poetical spirit in many of his descriptions, and reveals to us the joy of possessing an eye which goes beyond the *outside* of the objects around it.

Handbook of Instructions for Collectors. Pp. v + 137; illustrated. (London: Printed for the Trustees of the British Museum, 1902.)

WITH the view of obtaining the aid of naval and military officers, explorers, missionaries and others whose duty or inclination takes them to foreign lands in adding to the collections of the Natural History Branch of the British Museum, the Trustees have issued this excellent little handbook. It consists of a series of pamphlets describing the methods of collecting and preserving the various groups of animals, as well as plants, fossils and minerals. The different sections into which the book is divided have been written by members of the staff of the Museum, each of whom is a specialist in his own particular branch, and although the manner of treatment varies somewhat, each section is admirably adapted to its special subject, illustrations being introduced when necessary. The section on mammal collecting is divided into two parts, one dealing with the larger and the other with the smaller forms, a feature of the former being the inclusion of a list of species specially wanted by the Museum. Birds and the lower vertebrates follow next, after which come the various invertebrate groups, the work closing with chapters on plant and mineral collecting. The book is of a size convenient to be carried in the pocket, and has the corners rounded off the better to withstand constant use. R. L.

The First Principles of Ratio and Proportion and their Application to Geometry. By H. W. Croome Smith, B.A. Pp. iv + 32. (London: Macmillan and Co., Ltd.) Price 1*s.*

THE strict theory of geometrical proportion is difficult, and, with few exceptions, elementary students are quite unable to understand it. Opinions differ as to the compromise that is best suited for school teaching, and suggestions on this topic deserve careful consideration. Mr. Smith bases his method on the variation of two geometrical quantities; it is supposed that they vanish together and that any given increment of the one is associated with a fixed increment in the other; or, as he puts it, "when two variables change in such a way that equal changes in the one are accompanied *always* by equal changes in the other." A theory of proportion which starts from this idea is necessarily imperfect, and ignores the most troublesome part of the subject; but it will probably serve very well as a provisional compromise. At any rate, Mr. Smith's book deserves a trial.

Year-book of the Scientific and Learned Societies of Great Britain and Ireland. Pp. viii + 295. (London: Charles Griffin and Co., Ltd., 1902.) Price 7*s.* 6*d.*

THE nineteenth annual issue of this handy book of reference does not deal with a single calendar year, but with an actual working year of the great majority of the learned societies. Consequently, there are here brought together the papers read before the chief scientific societies throughout the United Kingdom from October, 1901, to June, 1902. The list of societies included in the new volume seems fairly complete, but we notice that the Geographical Association is not mentioned.

Papers on Etherification and on the Constitution of Salts. By Alexander W. Williamson, LL.D., F.R.S. (1850–1856.) Alembic Club Reprints, No. 16. Pp. 62. (Edinburgh: Published by the Alembic Club. Edinburgh agent, William F. Clay. London agents, Simpkin, Marshall, Hamilton, Kent and Co., Ltd., 1902.) Price 1*s.* 6*d.* net.

THE Alembic Club is doing valuable work by reprinting the accounts of classical researches in science in the words of the experimenters themselves. We are glad to know these reprints are increasing in popularity among teachers of science in schools where the "research" method of obtaining knowledge is encouraged. It is a matter for gratification, too, that this collection of papers, which have appeared in the publications of various scientific societies, has been printed during the author's lifetime.

Dove Dale Revisited: with Other Holiday Sketches. By the Amateur Angler. Pp. xiv + 130. (London: Sampson Low, Marston and Co., Ltd., 1902.) Price 2*s.* 6*d.* net.

THE amateur angler writes pleasantly of a beautiful country for which he has great affection. The volume is the seventh and concluding one of a series, and will encourage its readers to take an intelligent interest in animate and inanimate nature. The illustrations are numerous and exceptionally good.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Volcanic Dust Phenomena.

THE phenomena connected with the volcanic dust are undergoing distinct changes. In common with observers in the south of England, I noted the fresh appearance of the dust phenomena in the end of June, especially on June 26, but they were not very striking until August 1. At first the most decidedly volcanic feature was the great corona round the sun, known in the case of the Krakatoa effects as "Bishop's Ring." Whether this name should be applied to the corona this year is doubtful, as its radius has been fully double that of the Krakatoa corona, having until recently averaged about 70°, measured from the sun to the middle of the reddest part. Yesterday and this morning, however, it averaged only about 40°, and its reddest part was a yellowish-brown rather than a red. The colour of the corona this year has always been much less decidedly pink than was the case with Bishop's ring; indeed, it has sometimes been an absence of blueness in that part of the sky rather than any positive redness.

The pink glows after sunset were very strong in the end of June, but stronger still in November, and on November 1, 17 and 18 there was also a faint second glow, a phenomenon I had not previously seen since the Krakatoa sunsets.

It was not until October 30 that the colouring became very magnificent, and it reached its height about November 1, when the chief feature was an intense fiery orange sky near the west horizon. This was of an unmistakably volcanic character, different from anything that has appeared here since the Krakatoa sunsets, though not equal to those in splendour. Since that maximum, the colouring has been gradually lessening. Yesterday and to-day it was remarkably weak, the chief feature being the dust-wisps, which were more conspicuous than I have previously seen them during this apparition; indeed, I should have at first taken them for clouds had I not previously seen them in feebler form. They were plainest a little after sunrise and before sunset, when they were very bright and of a steely white.

The above descriptions apply to Sunderland; but in visits to Torquay from November 6 to 10 and to Dundee about December 1, the sky effects were not very different, only at Torquay I did not see the fiery orange.

Sunderland, December 16. T. W. BACKHOUSE.

P.S.—December 22. The fiery orange has reappeared.

The Methods of Investigating the North Sea Fisheries.

MANY of the readers of NATURE are interested in the international scheme of scientific investigation of the North Sea; but some at least are not convinced that the methods which are being employed are capable of yielding results of value as regards the condition of our fisheries.

The *essential* part of the scheme formulated at the conference at Christiania, at which the British delegates were Sir Colin Scott Moncrieff, Prof. D'Arcy Thomson, Mr. Garstang and Dr. Mill, is that each nation should fit out one or two specially equipped steamers, which should work along definite lines, and by means of which investigations as to the state of the fisheries, as well as hydrographical and biological investigations, should be conducted. The British Government agreed to participate in the prosecution of this scheme

But it has been repeatedly pointed out that, if conclusions as to the fisheries are to be drawn from the work of these steamers, two assumptions have to be made.

(1) That the take per steamer or per capturing unit is a measure of the abundance of fish, and

(2) That samples taken from small areas are representative of adjacent districts.

Both these assumptions have been severely criticised, and we had hoped that before now Mr. Garstang would have fulfilled the promise made by him in his letter to the *Times* of April 14 of this year; when he said, in reply to certain criticisms made by others and myself, that he "could see no reason for anticipating the reply which in due course and in the proper place will be made to the real authors of the criticism he (*i.e.* the present writer) adopts."

It will be remembered, (1) that the criticism referred to is that made by the Inspectors of Fisheries in their Report for 1900 upon the method of estimating variations in the density or abundance of fish by variations in the take per capturing unit, which was employed by Mr. Garstang in his "Impoverishment of the Sea." (2) That that criticism was published at least eighteen months ago, and that it is still unanswered by Mr. Garstang.

It was expected that at the meeting of the British Association at Belfast he would have taken the opportunity of meeting these criticisms. But he does not seem to have done so. For in reply to a letter asking him if he could refer me to any published refutation of these criticisms, he writes under date December 8, 1902, "I am unable to refer you to any published replies by me to the 'criticism' you quote, other than the *Times* reports of the Belfast meeting of the British Association and the Grimsby Conference of the National Sea Fisheries Protection Association (September 30 and October 1)."

The summaries of his communication at Belfast in the *Times* of September 13 and that in the *Times* of October 1 of his remarks at Grimsby give no indication that he dealt with the criticism, a criticism which, if it is valid, renders the results of the investigations recorded in his "Impoverishment of the Sea" of no value, and—what is of greater importance—throws grave doubts on the results to be expected from the international investigations at present in progress.

The publication of the Report of the Departmental Committee on Ichthyological Research, which has just been presented to Parliament, must be looked forward to with interest, since the Committee must necessarily have given some expression of opinion upon the questions touched upon in this letter.

D. NOËL PATON.

22 Lynedoch Place, Edinburgh, December 14.

Carved and Perforated Antlers.

IN NATURE for November 20, p. 55, there is a reference to the probable use of the carved and sometimes perforated antlers, by some called "batons de commandement." By Mr. A. W. Franks and others, in the "Reliquiæ Aquitanicæ," the simpler forms are recognised as the "Pogamagan" (*striker*) of the North American Indian (pp. 40, 50, 189, 200, and pp. 30, 102, 159 and 180, of description of the plates iii. and iv., xv. and xvi., xxx. and xxxi.). It seems to me important to mention that in Westminster Abbey a Pogamagan is sculptured as being held in the right hand of a North American warrior on Colonel Townshend's mural tombstone (dated near the end of the eighteenth century), on the south side of the nave.

December 13. T. RUPERT JONES.

St. Elmo's Fire during Snow Storm.

[MR. W. N. SHAW, secretary to the Meteorological Council, has kindly forwarded to us the following letter received at the Meteorological Office.—EDITOR.]

IT may be interesting to your Society to know that we find in a report received from our local committee at Margate relative to the launch of one of our lifeboats there, viz. *Eliza Harriet*, on December 3 and 4, that it is stated that about 2 a.m. a bright light was observed on the top of each of the lifeboat's masts, also one on the lee foreyard, which remained quite three-quarters of an hour and lit up all the wire pennants, making them perfectly clear. The lights in question appeared to be of the size of a small lantern. At the time it was blowing very hard and a heavy sea was running, and during the whole time it snowed so hard that it was impossible to see a yard in front of the boat. These lights continued until nearly 4 a.m. and finally disappeared on the snow lifting. It could not possibly have been a reflection from any light on the lifeboat, as they had none showing. It seems to us that this was probably a case of St. Elmo's fire, occasionally seen in a highly electrified state of atmosphere. CHARLES DIBDIN, Secretary.

Royal National Lifeboat Institution,
Adelphi, London, W.C., December 12.

THE FARTHEST SOUTH.[1]

IT is with a feeling of disappointment that one learns that the name of Tierra del Fuego does not carry in it the tradition of the volcanic fires which, though once seen by man, are now nearly all extinct; but we are told that the name was given by Magellan because of the immense number of fires lighted by the native Indians to keep themselves warm or cook their food, or give notice of the approach of strange craft. All the descriptions of the country connect it in climate with Chili, the land of snow, as its native name implies, and give greater prominence to its glaciers and icebergs than to its one still active volcano.

Fitzgerald has given a fuller account of the exploration of the same region as that traversed by Sir Martin Conway, and the aspects of Nature which struck both these travellers we may regard as characteristic of the region.

FIG. 1.—Nieves Penitentes in Process of Formation. (From Conway's "Aconcagua and Tierra del Fuego.")

Many of the accidents and incidents, often very untoward, which befell them both may be expected as inevitable accompaniments of exploration at great elevations, while others may be provided against when the traveller has realised what is before him and taken due precautions. Both watched the purple shadows creeping over the ocean, the gorgeous colours of the rocks and the deep blue of the ice. Both tell us of the rapidly rising torrent which carried off mule and man, of the glissade of the ponies down the steep talus of crumbling stone, of the struggle and recovery of the mule on the slippery rocks, of the frost-bitten guide, the mountain-sickness and other discomforts arising from impaired circulation and the want of constant supplies of warm and nourishing food, of the difficulties of the dense forest and spongy ground; and this similarity of experience and consensus of opinion warns the future traveller who may try those heights what to look out for and what to prepare for.

[1] "Aconcagua and Tierra del Fuego." By Sir M. Conway. Pp. xii + 252. (London: Cassell and Co., Ltd., 1902.) Price 12s. 6d. net.

Sir Martin Conway's diary, in its description of details, gives a freshness and local colouring to the story; even his constant references to the weather, by which, in such cases, the best-laid plans are often thwarted, do, in spite of Mark Twain's grumble, help the reader to realise the nature of the enterprise. Perhaps this remark would apply less strongly to his introduction of unexplained Spanish or native words with which his readers could not be expected to be familiar. We certainly do feel that we are reading about a foreign country when we come suddenly upon alameda, alfalfa, arriero, or pejerey, peon and posado. They have their effect, like "that blessed word Mesopotamia"; but we lose the thread of the story if we do not know whether our traveller has arrived at a wayside inn or a position of equilibrium at the bottom of a crevasse.

Darwin, in the "Voyage of the *Beagle*," has described the features of this interesting region more especially from the scientific point of view; Sir Martin Conway often helps us greatly to realise the general effect by pointing out that it is like something nearer home which his readers would probably have seen.

It is an interesting region. The double range of the Andes carved into every variety of peak and valley is submerged at its southern end so that the deeper hollows have been invaded by the sea, which fills a long trough parallel to the coast-line and many a transverse channel. He compares it to the Norwegian and Alaskan inland steamboat routes (p. 141). The submerged mountains are attacked by air and ocean with almost ceaseless fury, and we learn that it is not always safe to assume, when we see the tops of a group of mountains all touching an approximately uniform level, that we have there the wreck of a sea-plain or, as some would call it, a plane of marine denudation or base level of erosion, out of which the separating valleys have been carved after its upheaval, for here we have an example of a mountain region being submerged and the heights during any stationary period being planed off to a uniform level, the valleys having existed previous to the submergence.

The mountains around still rise so high that their snows feed glaciers which descend to sea-level. Before the submergence, their greater ice-flows crept further out on to the lowlands and left traces of ancient glaciation far beyond its present limit.

How recent some of the great geographical and climatal changes of the southern end of the Andes are, we may learn from a comparison of what the glaciers of Sarmiento were like when Darwin visited the straits and the same glaciers as seen by Sir Martin Conway. In

Darwin's time, they actually ended in the water, now they are cut off from the channel by belts of densely wooded moraine. The former greater extension of the ice is also shown by the way in which "the graceful ice-rounded foundation rocks of this and all the other mountains around slope up to the cliff and jagged arrêtes above" (p. 199), and proofs of oscillations of level are seen in the raised beaches and iceberg-carried boulders near Otway Water (p. 219).

Aconcagua (pp. 71, 72) towers into the sky, the grandest peak of the southern Andes. It appears to be built up of approximately horizontal beds of volcanic rock of different texture, hardness and friability, which are carved into steps like those which gave their name to the "trap" rocks of Sweden. The steps are better preserved towards the right- and left-hand sides of the slope than in the middle, where the downward drift of débris and the fall of avalanches are most common. The edges of the steps are there completely worn away and buried. The flow of débris down the face is such that the fragments tend to become rounded or subangular, like pebbles in a brook by their friction against one another. When he was descending the mountain, the stones at one point (about 20,500 feet up) poured away beneath his feet and disclosed the subjacent rock, which he perceived to be ground quite smooth by the passage of the débris over it.

Sir Martin gave some time to the examination of those curious remnants of great slipped or drifted masses of snow, the *nieves penitentes*, so called because they stand like devotees enveloped in shroud-like robes doing penance. They require peculiar conditions for their full development, and therefore, although somewhat similar pillar-like remnants of melting snow may sometimes be seen even in this country, they are not common anywhere in the Old World and only over limited areas in South America. They are cut out of avalanche snow which has been subjected to pressures roughly perpendicular to the direction of its fall, and thus hardened into approximately vertical strata of different densities. The wind has nothing to do with their origin, but they are carved out by the melting action of direct solar radiation. They are roughly elliptical and somewhat bent over to the north, the major axis of the elliptic sections being oriented east and west. On searching for *penitentes* in different stages of development, he found that a thick bed of well-compacted snow, when exposed to the action of the sun, soon becomes pitted over with little saucer-like depressions, and the deeper these become, the less power has the sun's rays upon their sides and the more upon the bottoms of the depressions. The hollows enlarging ultimately run into one another, leaving rough pyramids of snow standing up between them, until at last the ground is reached; the spires are entirely separated from one another and are seen standing about on the stony floor like separate sugar cones.

FIG. 2.—Nieves Penitentes; the last stage. (From Conway's "Aconcagua and Tierra del Fuego.")

There is also a mountain called Penitentes (p. 108), from the weathered-out columnar structure of the rocks which form its summit, not unlike what we sometimes see in our strongly jointed Mountain Limestone or Millstone Grit.

Many other curious questions arise out of an examination of such an area; for instance, the great unconformity (p. 105); the inosculating valleys (pp. 127, 131); the landslips and rock creep, or rivers of mud and stone, similar to those described by Heim in Switzerland; the moraines modified by blown sand (pp. 55, 56).

So little has been done towards the exploration of those strangely varied and, for most people, inaccessible regions that we gladly welcome Sir Martin Conway's diary of his adventurous journey through southern Chili and Tierra del Fuega, and of his difficult climb and almost equally dangerous descent of Aconcagua and Sarmiento. T. McK. H.

SECONDARY AND TECHNICAL EDUCATION.

NOW that the Education Act has become law, one of the first duties of the newly constituted local authorities will be to determine what are the educational needs of their districts and how far these needs are met by existing institutions; they will then be able to decide in what directions increased educational facilities are needed and how they can most efficiently provide what is wanted.

It is in the domain of secondary education that such a survey as is foreshadowed above is likely to form most

frequently the basis for a demand for a revision of the curricula of some of the schools in the district. Thus, in many of the administrative counties, we still have too many schools which devote a large amount of time to the study of classics, not because most of their pupils are best fitted for life by such study, but mainly because the school prepares each year a boy or two for Oxford or Cambridge. Wise county councils will probably decide to limit the number of classical schools within their counties, sending, by means of scholarships, the best boys capable and desirous of receiving a good classical education to one or more selected schools in the district. The remaining county grammar schools will, it may be hoped, be modernised and adapted to the needs of the bulk of the pupils attending them. In many, a strong agricultural side should be developed; in some, a good modern education should be given.

It will be asked, "What is here meant by a good modern education?" In the opinion of the writer, this should include English—taught much more thoroughly than is usually the case in grammar schools, where classics absorb the lion's share of the pupil's time—and mathematics, based on practical measurements and including a knowledge of geometry gained by methods more suitable for boys and girls than those set forth in Euclid's elements. German, taught by colloquial methods, should be a compulsory subject because the study of its grammatical peculiarities forms a mental training as useful as can be given through the medium of Latin or Greek, and because it is becoming increasingly difficult for one who does not know this language to follow the latest developments in either industry or commerce. French should also be taught where possible, but in cases where only one language can be learned, it should be German. Drawing would naturally form part of the course, and some suitable form of manual training, such as modelling or woodwork, should be introduced.

Above all, it is to be hoped that local authorities will discourage the pseudo-classical schools which have sprung up in the last two decades owing to the desire of some ancient grammar schools to meet the demand for the teaching of modern subjects while still devoting some portion of the school time to Latin. The result is—what might be expected—that neither Latin nor modern subjects are mastered; the pupil has a smattering of too many things.

Although a diminution in the amount of classical teaching is here advocated, it must not be supposed that the value of sound classical training is underestimated; where a pupil's time suffices for this as well as for the subjects he needs to enable him to earn his living, it is well that he should study Latin and, if possible, Greek. But in cases where the school life of a boy or girl is necessarily limited, it is much better that his or her mind should be trained through the medium of subjects likely to be of greater service in after life; above all, it is very doubtful whether a child obtains any substantial benefit from a classical training so imperfect that he remains unable to appreciate, or even to read easily, classical literature.

In the towns, the matter will be more complicated. Many local authorities will have to determine how best to deal with the higher grade board schools, where they exist. In each town, the problem will be different; where the towns are badly provided with secondary schools, it may be wise to convert the higher grade board schools into secondary schools, but, in such cases, they should not be allowed to strangle existing efficient secondary schools by providing education of the same kind as these schools offer, practically free of charge. If the circumstances of the town make it desirable that secondary education of a certain type should be offered free, then all the schools of this type should be placed in a position to offer the same terms to their pupils, so that such competition as exists will depend only on the relative efficiency of the teaching in the schools. On the other hand, in some towns the higher grade board schools have been competing needlessly with secondary schools in their neighbourhood. In such towns, the higher grade board schools can be converted into higher elementary schools, giving a training for the large number of boys and girls who must leave school at a comparatively early maximum age, say fourteen or fifteen. Indeed, as recent Parliamentary returns show, there are, in most higher grade schools, very few boys or girls above fifteen, except backward ones. The curricula of these schools should be materially altered; they are at present far too ambitious, having regard to the average age at which their pupils leave, and should be amended so as to include only that amount of work which can be satisfactorily covered, and the comparatively few pupils for whom the present curricula are devised should be transferred, by means of scholarships, to secondary schools.

One of the most fertile causes of the comparative inefficiency of some of the secondary schools in this country is the large number of examinations for which they find it necessary to prepare their students. Thus we have, not only the examinations of the Board of Education, but also the local examinations of the various universities, special examinations for the Army, the Navy, the Civil Service, different county and other scholarships, &c. It would be an enormous gain if, in place of all these various examinations, we had one State examination, on the results of which there would be issued a certificate, guaranteeing a good general education and recognised as qualifying for admission to the universities, the Civil Service, the Army, the Navy, &c. Unfortunately, enormous vested interests are opposed to such a plan, as the present system of indefinite multiplication of examinations finds employment for a large number of examiners and is stamped with approval by the action of the older universities, which have in recent years extended their system of local examinations so as to include quite young children; *e.g.*, the maximum age for admission to a so-called "honours" class in the preliminary local examination of the University of Cambridge is fourteen!

Assuming that a suitable basis for technical education has been made by the provision of an adequate number of secondary schools, it will then be necessary to consider what technical institutions are needed in the district. This will, of course, depend largely on the nature of the industries which exist in particular neighbourhoods. In many administrative counties, the only technical institution needed will be an agricultural college, and for some counties a share in an agricultural college would suffice. In other administrative counties, provision must be made for proper technical instruction in such subjects as coal mining, metallurgy, fisheries, &c. But, as a rule, the county will find much of what it wants in the large technical colleges already existing in the great cities within, or adjacent to, the geographical borders of the county.

In many of the smaller county boroughs, there are already technical schools providing evening classes for artisans; in the remainder, such evening classes might not infrequently be provided in connection with the modern secondary school of the place. In large cities, which are great centres of population, a first-class technical institution will be needed, providing not only evening classes but more especially instruction for adult day students on a par with that given in Germany and the United States. This can only be done effectively by concentrating in one institution for each district either all the higher technical education or, at least, the highest part of such education in a certain number of branches of technology and commerce. For it is only in institutions with numerous pupils that it is economically justifiable to provide the expensive equipment needed for such work

and the large number of highly paid specialist teachers who ought to be employed therein.

At present there is no technical institution in the United Kingdom which is staffed on a scale even approximately equal to that of such foreign institutions as the Charlottenburg Technical High School, Berlin, and the Massachusetts Institute of Technology, Boston. In these magnificent technical high schools, in place of two or three professors, *e.g.*, of engineering, we find a very large number of highly qualified men, each dealing with some special branch of engineering knowledge, and this can be economically done because of the very large number of engineering students gathered together in one institution. In this country, at present our comparatively few adult engineering day students are scattered among a relatively large number of institutions; as a result, such far-reaching subjects as electrical engineering have to be entrusted to a single professor. Indeed, there are some technical colleges in which there is only one professor of engineering, and electrical engineering is in charge of a poorly paid assistant lecturer.

To remedy this, coordination of work is necessary, not merely within the great towns, but even between neighbouring educational authorities, which are not infrequently jealous of one another and pursue their work regardless of what is going on around them. Hence we have cases of towns within easy reach of one another where technical institutions have been established, each of which tries to do the highest possible work in all the subjects which it undertakes. The result is a small number of students in each subject in each town and a staff of teachers proportionate, it is true, to the number of students, but inadequate for the purposes of advanced technical education. It would be well, therefore, if power were given to the Board of Education to select a limited number of central institutions where alone higher technical education in the day-time should be given.

Liberal financial aid will be needed to place such institutions on a satisfactory basis, and as they will be national rather than local institutions, a large part of the money for their support should be provided from the imperial exchequer; the remainder should be contributed by the various local authorities in the districts which they serve.

Another important matter which must be determined is the relation of institutions providing the highest kind of technical training to the universities or university colleges in the same district. The best solution of this problem in such a case as, *e.g.* Manchester would be for the technical institution to absorb all the higher technical work of the city and for the university college to devote itself to the faculties of theology, literature, philosophy, medicine, law, pure science, music, &c. Where local universities are established, the technical institution would become the faculty of technology and commerce; it should not be subjected to the academic control of the university, which might tend to destroy its usefulness for industrial and commercial purposes.

The great technical institutions of Germany and America exist side by side with important universities; they are, however, independent of these, and it is partly to this fact that they owe their usefulness in promoting the industrial progress of the German and American nations.

An important problem for the new local educational authorities will be the training of teachers of trade subjects. It is easy to find men with a good knowledge of their respective trades, or persons who can teach well, with a superficial knowledge of an industry, but the combination of these qualifications is comparatively rare. It is not easy to see how this can be speedily remedied, but an improvement might be produced by arranging a higher scale of remuneration for teachers of trade subjects who had passed examinations giving evidence of their power to explain in simple language matters connected with their own industry. More than this it is probably impossible to demand at present.

As regards the more highly qualified teachers needed for adult day classes in technical institutions, one of the greatest difficulties is how best to keep such men in touch with their respective industries. If the teacher's whole time is not required for the work of the institution, he can remain in contact with the industry by doing consulting work and by research. Unfortunately, in such cases there is often a tendency for him to regard his teaching work as the least important part of his occupation; in fact, one has known cases where the principal value of such a teacher to his students has been the fact that his name was well known in the industry and his recommendation consequently a valuable one, though his actual teaching work was of a merely nominal character. The cure for this would be to make the pay which the teacher receives for teaching by far the largest part of his income; such an arrangement would, however, mean a considerable increase in the salaries of teachers of technical subjects, but, in the opinion of the writer, it would be justifiable, as it would make it possible for some of the best men to continue teachers; at present, such men are attracted to the industries by the incomparably larger financial prizes which they offer. J. WERTHEIMER.

PREVENTION OF RABIES.

A LETTER headed "Mr. Hanbury admits the failure of the muzzle" has been addressed to us by a member of the executive committee of the National Canine Defence League, which letter, as might be expected, urges in so many words on behalf of the canine species the total abolition of the muzzling order at all times and under all conditions. The writer of the letter vindicates for himself, as might also be expected, a superior knowledge concerning rabies, its nature and its mode of spread; he, as a matter of course, is one "who understands dogs" and considers "that the muzzle was from the first condemned as useless cruelty." According to this authority, the Board of Agriculture, including, we presume, its veterinary department, "itself ignorant of dogs and their diseases, has persistently refused to be advised and guided by those who do possess the requisite knowledge" (*sic!*).

To be serious, it is no new thing that there never is any lack of amateurs who, notwithstanding the obvious want of special knowledge required to form an opinion, are in their own estimation quite capable of judging of the merits or demerits of a question that can be only dealt with adequately by the specialist possessed of the requisite knowledge.

Rabies is an infectious disease, directly communicated by the bite of a rabid animal, in the vast majority of cases a rabid dog. In the interest of the animals themselves—all domestic animals are susceptible to the disease—and above all in the interest of human beings, the disease should be, and as a matter of fact has been, controlled, checked and prevented from spreading by the thorough, not half-hearted, carrying out of the muzzling order: that is, the slaughter of ownerless and stray dogs—the most dangerous because the most frequent means of contagion—and by the muzzling, not merely the pretence of muzzling, of all dogs, so as to include also those that may and sometimes do harbour the contagium before the actual disease has fully declared itself in them. Such is the practice, the only rational practice, which is followed, and successfully followed, in other countries at times when rabies makes its appearance. The private opinion of Mr. Hanbury or any other politician on this subject, and the complaint that—owing, most probably, to the loose and half-hearted manner of

administering the muzzling order—rabies has not been stamped out in Wales, does not touch the real merits of the question.

Mr. Long, the former President of the Board of Agriculture, who has proved himself thoroughly well instructed in the whole question of rabies, has with laudable firmness resisted the outcry and the repeated assaults of the uninstructed sentimentalists, and as a result was able to demonstrate that by the strict carrying out of the muzzling order rabies in England was checked and was almost reduced to extinction, though at first it was so prevalent as to be really alarming. It seems hopeless to discuss this or any other dog-question with people who, in the face of all expert opinion as regards prevention of rabies, and particularly against the opinion of sensible owners of dogs, can write that "the muzzling order and the muzzle are a gross and wanton cruelty to animals."

But even if it were not an exaggeration, as we are persuaded it is, that the owners of dogs in general object to the muzzling order and consider it a cruelty to animals, what about the human species? Human beings who are not members of the executive committee of the National Canine Defence League regard the muzzling order as an important safeguard. One of the duties of the State is to protect the health and lives of its citizens. Hydrophobia of man is one of the most terrible diseases, and the slaughter of stray dogs and the muzzling of all dogs in places where rabies is rife has been proved to be at present the best and only means to prevent the spread of the disease to man. Besides, it should be the interest of owners of valuable animals to insist on the retention and strict carrying out of a measure which to a very large extent insures against the spread of rabies and consequent loss—seemingly of indifference to the members of the Canine Defence League.

RECENT WORK OF THE GEOLOGICAL SURVEY.

The Report referred to below[1] shows that the Geological Survey continues with activity and success its investigation of the geology of these islands. It bears witness to a large amount of steady and useful routine work, which may not make much show, but which will contribute to our knowledge of the detailed structure of these islands and in some instances will have direct economic usefulness. Among the more interesting scientific results of the year's work, the progress of the re-examination of Cornwall has brought to light evidence of a younger granite than the main mass of that rock, showing that the granitic intrusions form a somewhat more complex series than had been supposed. The clue, however, to the detailed structure of the so-called "killas" and the boundaries between the true Devonian and older rocks still eludes the keen eyes with which the surveyors are searching for it. If we could hope that the appointment of a mining geologist would do anything towards reviving the decayed mining industry of the region, we should still more rejoice in this increase to the strength of the staff. Another of the problems which for years past has baffled the officers of the Survey is that of the Old Red Sandstone of South Wales. They are still unable to draw any satisfactory line between the lower and upper divisions of the system. If the key is not found before the western coast is reached, we can hardly hope that it will be discovered in any part of this region.

Some interesting discoveries were made during the year in Scotland. Foremost among these is the finding of proof that the granite of south-west Argyllshire has invaded and altered a portion of the Lower Old Red Sandstone series of Lorne. The importance of this new fact lies in its relation to the history of the metamorphism and igneous protrusions of the Scottish Highlands, for it shows that some of the granitic masses, like those of Galloway and Leinster, are certainly post-Silurian in age. Another notable "find" is that of the zone of *Pecten asper* in the island of Scalpay and of Upper Cretaceous rocks in the sound of Soay.

In Ireland, the energies of the Survey are now concentrated on the Drift, with the view of preparing accurate maps of the superficial deposits of the country. But under Mr. Lamplugh's direction, the geological interest of the glacial geology is not likely to be lost sight of. One of the features of the work in the Dublin district was the finding of evidence which seems to support the view that the eskers represent water-channels which existed under the ice-sheet.

A new arrangement has been made in this Summary. Its materials are grouped by districts instead of, as formerly, by formations. The change will no doubt save trouble in the preparation of the volume, but it gives a great deal more to the geologist who wishes to ascertain what additions to our knowledge the Survey has been able to make in any particular part of the geological record. Another change is the omission of the Director's name from the book. It surely cannot have been the wish of those who wield the new brooms at South Kensington to sweep Mr. Teall's name clean out of his Report.

[1] "Summary of Progress of the Geological Survey of the United Kingdom and Museum of Practical Geology for 1901."

PROF. P. P. DÉHERAIN.

Déherain (b. 1830, d. 1902), who in 1887 succeeded to Boussingault's place in the Académie des Sciences, was, for the last twenty-two years of his life, professor of vegetable physiology as applied to agriculture at the Muséum in Paris. His early work was chiefly agricultural, and included researches on calcium phosphate, on the salts of potassium, &c.; he was author of a "Cours de Chimie agricole," and it should not be forgotten that he founded the *Annales agronomiques*. In the region of pure physiology, he was author of a number of memoirs, of which those written in collaboration with Maquenne, Moissan and others are perhaps especially well known. He worked at gaseous interchange, including the absorption of oxygen by succulents and by oily seeds, also at the assimilation of CO_2, being especially interested in the action of the different parts of the spectrum on this process. His researches extended to other subjects, such as transpiration, the assimilation of free nitrogen and denitrification.

A sympathetic appreciation of his personal character and of his career as a teacher is given by his former pupil, Maquenne, in *La Nature* of December 13, to which we acknowledge our indebtedness. Although Déherain's name is not associated with any great discovery, he deserves the place he won for himself in the annals of plant-physiology and the honour due to one who dies in harness. F. D.

TRANSATLANTIC WIRELESS TELEGRAPHY.

Mr. Marconi's latest success is a wonderful achievement. Messages have been exchanged in both directions across the Atlantic, between his two new stations at Glace Bay, Cape Breton, and Poldhu, Cornwall. Transatlantic wireless telegraphy has thus been successfully established; and the persistent effort which has enabled this result to be accomplished merits the fullest recognition. The messages which we print from the *Times* represent the inauguration of a system of

communication which is not only of the highest scientific interest, but also of practical importance.

The following messages and particulars referring to them appeared in the *Times* of December 22 and December 23:—

Ottawa, December 21.

The first message to be sent across the Atlantic Ocean by wireless telegraphy was despatched to-day to King Edward by Lord Minto. Notice of its successful transmission was received to-night by the Governor in the following message:—

"Glace Bay, Cape Breton.

"I have the honour to inform your Excellency that your message to his Majesty has now been transmitted by me from Cape Breton to Cornwall by wireless telegraphy, and has been forwarded to its destination.—G. Marconi."

Lord Minto replied as follows:—

"I am delighted at your message, which I have just received. My warmest congratulations on your spendid success."

December 22.

King Edward has replied to Lord Minto's telegram sent to His Majesty by Signor Marconi's apparatus, as follows:—

"I am much interested by the wireless message which you have sent me, and am delighted at the success of Signor Marconi's great invention, which brings Great Britain and Canada into still closer connection.—Edward."

On Monday, the *Times* published the following message from its correspondent at Glace Bay:—

"Being present at its transmission in Signor Marconi's Canadian station, I have the honour to send through the *Times* the inventor's first wireless Transatlantic message of greeting to England and Italy."

The following message, also transmitted by wireless telegraphy, was published on Tuesday:—

The Government of Canada, through the *Times*, desires to congratulate the British people on the accomplishment by Marconi of the greatest feat which modern science has yet achieved.

"Cartwright, Acting Premier,
"Ottawa, December 21."

NOTES.

The King of Denmark has conferred upon Lord Lister the honour of Knighthood of the Grand Cross of the Order of Dannebrog.

M. Darboux, permanent secretary of the Paris Academy of Sciences, has been appointed a member of the Bureau des Longitudes in succession to the late Prof. Cornu.

Mr. C. A. Angot, of the Bureau central météorologique de France, and Prof. W. L. Moore, of the United States Weather Bureau, have been elected honorary members of the Royal Meteorological Society.

The council of the Manchester Literary and Philosophical Society has awarded the Wilde gold medal for 1903 to Prof. F. W. Clarke, of the United States Geological Survey, and a Dalton medal to Prof. Osborne Reynolds, F.R.S. In view of the fact that next year will mark the centenary of the discovery by Dalton of the atomic theory, Prof. Clarke (whose writings on the atomic weights are well known) has also been invited and has consented to deliver the Wilde lecture for 1903. The presentation of the medals and the delivery of the lecture will probably take place in May, 1903.

At the general meeting of the Zoological Society of London on December 18, it was announced that Mr. William Lutley Sclater had been selected by the council out of twenty-two applicants for the vacant post of secretary. Mr. Sclater is now director of the South African Museum, Cape Town, and has previously held appointments as science master at Eton and as assistant director of the Indian Museum, Calcutta. He is a well-known authority on the mammals and birds of India and Africa, and on other zoological subjects, and is at present editing a series of volumes on the fauna of South Africa, of which four have already been published.

We regret to record the death, on December 13, of Dr. John Young, late professor of natural history in Glasgow University since 1866.

The death is announced of Prof. Zaayer, professor of anatomy in the University of Leyden. The death is also announced of Prof. Leonard Landois, professor of physiology at the University of Greifswald (Pomerania).

Mr. T. Brice Phillips, of Uckfield, has been awarded the prize of fifty pounds, together with a silver medal, offered by the council of the Society of Arts for his essay on "Existing Laws, By-laws and Regulations Relating to Protection from Fire, with Criticisms and Suggestions." Prizes of ten pounds with a bronze medal have also been awarded to Mr. George H. Paul and to Dr. W. C. Henderson.

It is announced in *Science* that the Section of Geology and Geography of the American Association for the Advancement of Science, which will meet at Washington on December 27, has arranged to devote a session of the meeting to the discussion of the recent eruptions of Mont Pelée and La Soufrière by Messrs. Russell, Hill, Heilprin, Jaggar, Curtis and Hovey, who visited the islands of Martinique and St. Vincent a few months ago.

The Coats family have given 10,000*l.* between them to the cancer research scheme, 5000*l.* being from Sir Thomas Coats and family, and 5000*l.* from Mr. Archibald Coats and his two brothers. The *Times* states that a few more such contributions would bring the fund up to the required amount, and would enable the investigations to be carried through on the comprehensive lines indicated in the scheme which was formulated and is being directed by the Royal Colleges of Physicians and Surgeons.

A Reuter message states that at 9.30 a.m. on December 16, Andijan, in the province of Fergana, Russian Central Asia, was totally destroyed by an earthquake. Andijan is a town of about 50,000 inhabitants. According to a rough estimate, 16,000 houses have been destroyed and 2500 persons killed as a result of the earthquake. Subterranean rumblings and tremblings of the earth continue. At New Marghelan, the capital of Fergana province, the shock lasted nearly three minutes. The direction was from north-east to south-west.

A telegram to the Paris *Petit Journal*, dated December 17, states that for several days past Mount Vesuvius has been throwing out rock masses, vapour and dust.

We learn from the *Times* that news has been received at Stockholm that the Swedish Antarctic exploration ship *Antarctic* left Tierra del Fuego at the beginning of November on its second summer expedition. It was expected that the expedition, after some cartographic work and natural historical research in the northern and western portions of the Dirck Gerritz Archipelago, would arrive about December 10 at the winter quarters in Snow Hill Land, where Dr. Nordenskjöld would resume the leadership of the entire expedition. The *Antarctic* will probably return to Port Stanley (Falkland Islands) at the end of February or the beginning of March.

In the House of Commons on December 16, the President of the Board of Trade was asked whether he was aware that three dangerous varieties of colour-blindness escaped detection by the Board of Trade test, whilst many normal-sighted persons were rejected by it. In reply, Mr. Gerald Balfour said the present

system was adopted on the recommendation of a committee appointed by the council of the Royal Society, and that the Board of Trade in doubtful cases had the assistance of the gentleman who acted as secretary to the committee. The President of the Board of Trade said he did not think there was any necessity for a small departmental committee to reconsider the test in the light of recent discoveries, as had been suggested.

Mr. Francis Watts, Government Analyst and Agricultural Chemist for the Leeward Islands, sends us from Antigua the following particulars of recent high tides received from correspondents in various neighbouring islands, and possibly connected with changes due to the late volcanic disturbances:—*Barbuda.* During the month of October and early in November, the tide was abnormally high, the rise being from 18 inches to 2 feet above the ordinary. Old inhabitants do not remember a like rise, except perhaps in a severe gale such as a hurricane, and then only for a short time.—Oliver Nugent. *Nevis.* Tides unusually high for eight or nine days, commencing about November 1.—R. B. Roden. *Dominica.* Tides unusually high for few weeks ending November 12, the level being constantly at about high-water mark. No determination had been made whether this was caused by high tides or change of level.—W. H. Porter. *Tortola.* Tides much higher than usual—a fact generally commented upon and noticed while bathing. No exact observations made, but the difference could safely be put down as a foot in depth.—Dr. Cookman. Referring to these records, Mr. Watts remarks, "Of course, it may turn out that there has simply been an abnormally high tide throughout the Leeward Islands, but so far the tide does not seem to have returned to its normal height. Observations will be continued and submitted from time to time. It will not be a very easy matter to determine if there have been slight changes of level, particularly in places where the shore is very steep, as it is in many of the islands of volcanic origin."

An aëronautical problem of some interest, and of far less difficulty than the problem of artificial flight, is the performance of journeys across the sea in a balloon. In *La Nature* for November 15, Lieut.-Colonel G. Espitalier gives an illustrated account of M. Henri Hervé's balloon, the *Méditerranéen* No. 2, and the methods adopted for directing it at sea. In order to prevent the balloon from being depressed by a shower of rain, its top part terminates in a cone. Instead of trailing a single guide rope, M. Hervé proposes a system of "triangulation," consisting of a trailer floating at the end of a long rope behind the balloon, and a balance weight hanging in the water by a nearly vertical and shorter rope, the resistance of the latter body being necessarily smaller than that of the former. The sea itself furnishes an inexhaustible supply of ballast, and this can be drawn up into a cylindrical reservoir suspended above the balance weight, a suction hose being used for filling the reservoir when required. This "compensator" is fixed near the surface of the water. M. Hervé employs two deviators for diverting his balloon by the action of the water, one, which he calls a "minimum deviator," for angles of about 30°, and the other, the "maximum deviator," for angles which are alleged to reach as much as 70° or 80°. M. Hervé first experimented in this direction on the North Sea in 1886, and last year he transferred the seat of his operations to the Mediterranean.

In a message from Buenos Ayres, a correspondent of the *Times* states that Mr. Reginald Rankin made the ascent of Aconcagua alone on December 14, having been deserted by his native guide. Being caught by a snowstorm, Mr. Rankin spent the night in the open at 22,000 feet, and on December 15 walked and rode continuously to Puente del Inca, a journey of 12½ hours, with frostbitten hands and feet. His toes have had to be amputated, but his fingers will probably be saved.

Until recently, a rule has been in force in the Lahore Veterinary College prohibiting *post-mortem* examinations of cows or pigs or any other "sacred or prohibited animals." We learn from the *Pioneer Mail* that the principal has subjected the carcass of a bull to examination for educational purposes and has declared that in future the thing will be done as a matter of course. The Bengali Press is indignant and prophesies the most dire results to British rule if the practice is continued, but it is difficult to see how veterinary surgeons can be trained satisfactorily without practical dissection of the kind to which objection is taken.

In our correspondence columns of December 4 (p. 103), under the title "Germs in Space," the suggestion was made that the dust which reaches the earth from space may contain living as well as dead matter. Mr. John Munro writes to say that in the "Bijou" biography of Lord Kelvin, published some time ago, the same view is expressed in the following passage. The passage runs (p. 81):—"Nay, it seems rather a crude hypothesis, for the seeds of life may be floating like meteorites in space and ready to sow the crust of a new and virgin planet."

Dr. H. Hergesell, President of the International Aëronautical Committee, states that the results hitherto obtained from the monthly balloon ascents have justified in every way the continuation of the experiments, and that it is proposed to continue them during the year 1903. During the current year, about 110 registering balloons and 52 manned balloons have been sent up. In addition, kites have been regularly employed in Europe and Boston, U.S.; on two occasions, they were also flown from steamers on the Lake of Constance. The complete results for the year 1901 will be published shortly, and those for 1902 are also in the press.

Several interesting articles of a semi-scientific nature appear in the Christmas number of the *Gardener's Magazine*, notably the description by Mr. J. Yeld of a climbing tour through the south-western Alps, and a historical account of the gardens at Hampton Court by Mr. G. Gordon. A calendar for the new year is included in the issue.

An investigation into the causes of larch and spruce fir canker, by Mr. George Massee, forms the subject of a publication by the Board of Agriculture. The fungus which generally attacks the larch is *Dasyscypha calycina*, and an allied species, *Dasyscypha resinaria*, is mainly the source of trouble in spruce canker; but these species are not easily distinguishable except to the expert. These two forms are not confined to the larch and spruce, but they may attack certain pines and firs, while other species also are destructive to coniferous trees. Mr. Massee confirms Hartwig's conclusions that they are wound parasites and finds that aphides are frequently the cause of trouble, although late frosts, which induce rupture of the bark and consequently extrusion of sap, are also a source of danger. Seedlings and young trees may be protected by spraying, but in the case of older trees the disease cannot be eradicated.

A history of systematic botany prior to Linnæus is given by Dr. B. Schorler in the *Sitzungsberichte* of the "Isis" Society of Dresden. To Aristotle is attributed the commencement of the study of botany as a branch of science; Theophrastus observed about 450 plants, Dioscorides about 800. According to Dr. Schorler, the earliest herbariums now extant are those of Aldrovandi in Bologna, Girault in Paris, Caesalpini in Florence, Hernandez in Escurial (Spain), Rauwolff in Leiden, Harder in Ulm, Ratzenberger in Cassel, Caspar Bauhin in Basle and von Burser in Upsala.

In a series of articles upon the dissociation of matter, which have been published in some of the recent issues of the *Revue Scientifique*, M. Gustave le Bon gives an interesting account, partly historical and partly descriptive, of the experiments

performed by himself and others on radio-activity, and of the theories which have been based upon them. The final conclusion at which he arrives is that kathode rays, X-rays and all the various phenomena of radio-activity appear to be particular aspects of a new form of energy which is as common in nature as electricity or heat, and the closer study of which may reveal to us a connecting link between matter and energy.

WE have received a copy of vol. xvi. of the *Journal* of the College of Science of the Imperial University of Tokyo, which contains a number of interesting contributions on electrical subjects. The first of these, from the pen of Mr. Y. Homma, discusses some of the observations on atmospheric electricity made at the Central Meteorological Observatory of Japan, dealing more especially with the effects of wind, fog, rain and snow on the atmospheric potential. The remaining papers, six in number, are contributed by Prof. Nagaoka, Mr. K. Honda and others, and all deal with magnetostriction and other allied phenomena in ferromagnetic substances. Those interested in the subject may be referred to these papers as containing the records of much valuable experimental work.

REFERRING in these columns a few weeks ago to the manufacture of apparatus from vitreous silica, the hope was expressed that our manufacturers at home were not going to be left behind in the application of this art. We have since learnt that Messrs. Baird and Tatlock have been manufacturing silica vessels by Mr. Shenstone's process for the past eighteen months and are prepared to make a variety of apparatus to specification.

THE Paris correspondent of the *Times* states that an automobile system is to be tried on the lines of the Paris-Lyons-Marseilles Railway. The trial trip is to be made by three cars next June from Paris to Dijon, and it is hoped to cover the 300 kilometres in a little more than three hours, or at an average rate of about sixty miles an hour. Each car is to be of the same size as an ordinary corridor carriage and capable of seating forty passengers; the petroleum engine is at the front of the car. The cars are to be built by Messrs. Gardner and Serpollet and will have the same weight as a corridor carriage. At present it is only intended to try the system for passenger traffic, but if it is successful it will doubtless be widely extended. It is also announced that a similar system is to be tried on the North-Eastern Railway between Hartlepool and West Hartlepool, where there is keen competition between the railway and the tramway. These cars are to carry a petrol engine driving a dynamo which will generate electric current for the actual driving motors.

A BRIEF description of the laboratories recently fitted up for electrochemical analysis at the Chemical Institute at Nancy is given by M. Arth, director of the Institute, in *l'Éclairage Électrique* for December 13. There are two rooms, one of which serves as a balance and apparatus room, the other containing the working benches. The laboratory proper is fitted up with two double tables each capable of accommodating eight students and a single table having room for two more. Each student has at his disposal two sets of leads, which can be connected to a supply of suitable voltage, a rheostat, and terminals by means of which an ammeter and voltmeter can be put in circuit. There is one ammeter and voltmeter provided between the four students working at the same side of the table, so that they have to make their measurements in turn, but these are so connected that the measurements can be made without interrupting the circuit. Extra terminals are, however, provided, by means of which additional apparatus can be connected in circuit. The circuits are purposely so arranged that the operations are not made too automatic, but the student has to understand what he is doing each time he makes a connection or a measurement. A full set of platinum electrodes, dishes, &c., completes the equipment.

THE river terraces in New England form the subject of an essay by Prof. W. M. Davis (*Bulletin* Museum Comp. Zool., Harvard College, vol. xxxviii.). He discusses the formation of terraces in valleys occupied by drift, and urges the importance of studying them in plan as well as in section. He points out that they may be accounted for, firstly, by the behaviour of a meandering and swinging stream, slowly degrading the valley deposits; and, secondly, by the control exerted here and there over the lateral swinging of the stream through the opening up of previously buried rock-ledges. The effects of uplift on the formation of terraces and rock-platforms are duly considered.

A MEMOIR on the geology of Lower Strathspey, by Mr. L. W. Hinxman and Mr. J. S. Grant Wilson, has been issued by the Geological Survey. The region described, which is in the counties of Elgin and Banff, is formed mainly of igneous and metamorphic rocks with a considerable area of Old Red Sandstone. The metamorphic rocks include granulitic schistose rocks of the Central Highland or Moine schist type, and various quartzites, schists and limestones with associated igneous rocks, grouped as the Banffshire series. To this series the foliated granites belong, while of later date is the great granite mass of Ben Rinnes and the Convals, which forms the dominant feature of the district. The petrography is dealt with by Dr. Flett. Two divisions of Old Red Sandstone are noted, the Middle or Orcadian and the Upper, and between these there is unconformity, as the Upper Old Red Sandstone rests on the basal conglomerates of the Orcadian series and extends on to the crystalline schists. Dr. Traquair contributes an interesting note on the general distribution of fishes in the Old Red Sandstone, observing that there are "three distinct fish-faunæ," while Mr. Kidston, in a note on the fossil plants, remarks that they also show a clearly defined threefold division of this formation. Glacial drifts extend over much of the ground, with the exception of the higher hill tops, and they present many features of interest.

A SUPPLEMENTARY list of lantern slides, recently issued by Messrs. Newton and Co., contains particulars of many slides of scientific interest. Among the subjects of slides suitable for science lectures or lessons are British reptiles and other animals, photographed from life by Mr. D. English; butterflies and moths; trees and plants; photographs of ripples on mercury and water, by Dr. J. H. Vincent; sound waves, by Prof. R. W. Wood; and photomicrographs by Dr. Spitta to illustrate the morphology of the malarial parasite.

IN the November number of the *Field Naturalist's Quarterly*, Dr. G. Leighton reopens the question of adders swallowing their young. Although he is unable to cite any definite instance of the occurrence of the phenomenon, he shows that some of the objections which have been urged against it are based on a misinterpretation of anatomical facts, and demonstrates that there is nothing inherently impossible in its taking place. As the gullet of an adder is perfectly capable of containing the body of a field-mouse, and as frogs are known to live for a considerable time after being swallowed by snakes, there is no reason why young adders should not be swallowed by their parent without being killed. The question remains, however, to be proved by positive evidence. "Of the possibility of the phenomenon," writes the author, "we have not the slightest doubt, of the probability of it we have considerable doubt."

WE have received from the publisher, Herr G. Fischer, of Jena, an interesting pamphlet by Prof. Max Weber, of Amsterdam, entitled "The Indo-Australian Archipelago and the

History of its Fauna." In a previous essay, the author has adduced evidence to show that Celebes should be referred to the Oriental rather than to the Australasian region, the Moluccan Channel, and not the Macassar Strait, forming the division between the two areas. In the present communication, he endorses the opinion that marsupials and monotremes reached Australasia from Asia. According to the author's view, in pre-Tertiary—very likely Cretaceous—times Australia was united by land with Asia. A Euro-Asiatic fauna inhabited this land, from which during the Eocene a southern portion was cut off by partial submergence, this southern portion being the modern Australia and New Guinea, the home of monotremes, marsupials and ancient forms of other groups, such as cassowaries and birds-of-paradise, while widely distributed specialised types are wanting. Northwards extended a coral-sea, in the islands of which dwelt primitive rodents, insectivores and other ancient groups, with perhaps cuscuses. During the Miocene, great changes of level took place in the Archipelago, which attained its present form in the Pleistocene. Celebes was insulated early, Java late. Intermittent land-connections took place, which allowed of periodical immigrations of Asiatic forms from one side and of Australian types from the other. The question is left undecided whether the cuscuses of the Austro-Malay islands are remnants of the primitive Euro-Asiatic fauna or later immigrants from Australia. The suggestion is also made that the Australian and Philippine rodents are relicts of the original pre-Tertiary fauna, although it is admitted that the specialisation of Hydromys is against this. The author fails to see any evidence in favour of a former connection of Australasia with either South America or Antarctica.

THE Rev. George Grenfell, of the Baptist Missionary Society, has constructed a map of the Congo River between Leopoldville and Stanley Falls from running surveys made during 1884–89 in the steamers *Peace* and *Goodwill*. The map is in ten sections, two on a sheet, and the five sheets are published in a convenient case by the Royal Geographical Society. A reprint of Mr. Grenfell's article, "The Upper Congo as a Waterway," which was printed in the *Geographical Journal* for November, 1902, accompanies the map and serves the purpose of explanatory notes.

THE "Englishwoman's Year Book and Directory, 1903," shows in a most convincing manner the ever-increasing part that women are taking in the work of the world. The editor has again obtained able assistance in the preparation of many of the sections, those dealing with science, medicine and education being typical instances. The original work in science done by women workers, a list of colleges where women may study, the names of women holding college appointments, and a list of scientific societies of which women may be members, are some of the subjects included in the science section.

THE issue for 1903 of the well-known annual biographical dictionary, "Who's Who," is considerably larger than previous editions, though all the preliminary tables which have appeared in former years have been removed, except that enumerating the members of the Royal family and the obituary for the year ending September 30, 1902. As usual, prominence is given to the biographies of men who have distinguished themselves in various branches of science, whether pure or applied, and the information is generally trustworthy as well as interesting. The annual is one of the few which can justly be termed indispensable books of reference.

A TRANSLATION, by Prof. J. D. Everett, F.R.S., and Miss Alice Everett, of Dr. H. Hovestadt's "Jena Glass and its Scientific and Industrial Applications," which was reviewed in our issue for December 20, 1900, has been published by Messrs. Macmillan and Co., Ltd., at 15*s*. net. With a view to make the book as clear as possible to English readers, the translators have given the spirit rather than the letter of the original, and they have, in cases where it seemed desirable, added brief explanations, which are always distinguished from the text. Some few matters of subordinate interest have been condensed. The details of an important application of science to industry will, by the aid of this translation, now be accessible to British students and opticians unfamiliar with the German language.

THE permanent seismological commission appointed two years ago by the Imperial Academy of Sciences of St. Petersburg has recently issued its first report, a quarto volume of more than two hundred pages. Most of the papers are written in Russian, and only one of these is accompanied by a summary in French. Several communications deal with the foundation of the International Association of Seismology at Strassburg in 1901; in others, Prof. Lewitski describes experiments with simple seismoscopes and with seismographs the movements of which are registered mechanically. The president of the commission considers the theory of the horizontal pendulum and Mr. B. Galitzin that of other seismographs, the latter erroneously attributing Darwin's bifilar pendulum to Davison. General Pomerantzeff contributes an examination of the seismogram traced at Strassburg on June 24 1901, and concludes that it is extremely difficult to explain the oscillations of horizontal pendulums during earthquakes either by tilts of the ground or by horizontal displacements alone, although they might be produced by a combination of such movements.

A SPECIAL report on the mineral waters of Kansas has been made by Mr. E. H. S. Bailey, with the assistance of Messrs. E. B. Knerr, Crane and McFarland, for the University Geological Survey of Kansas, which is conducted under the authority of the Board of Regents of the University of Kansas. The volume runs to 343 pp. and is divided into two parts; the former provides a discussion of the subject of mineral waters in general, while the latter arranges and classifies those of Kansas and supplies full analyses of a great number of samples of them. Many illustrations and one or two maps add to the value and interest of the report.

OUR ASTRONOMICAL COLUMN.

COMET 1902 *d*.—Herr M. Ebell has calculated the following elements for this comet from observations made on December 3 (Königsberg), December 5 (Hamburg, two observations) and December 7 (Heidelberg):—

T = 1903 April 19·441 Berlin M.T.

$$\left.\begin{aligned} \omega &= 51^\circ\ 51'\cdot2 \\ \Omega &= 112\ \ 54\cdot9 \\ i &= 42\ \ 10\cdot5 \\ \log q &= 0\cdot17344 \end{aligned}\right\} 1902$$

The ephemeris which accompanies these elements estimates that the brightness of the comet on December 31 will be 2·4, its brightness on December 2 being taken as unity.

THE ALGOL VARIABLE R.V. (13, 1902) LYRÆ.—In *Circular* No. 66 of the Harvard College Observatory, Prof. Pickering gives the results of an examination of some of the Draper memorial photographs in regard to the new Algol variable, R.V. Lyræ, recently discovered by Mr. Stanley Williams. From a photograph taken July 11d. 18h. om., 1893, a correction of +4h. or −2h. to Mr. Williams's ephemeris is obtained, but which of these values is the right one Prof. Pickering has not yet been able to determine.

PROPER MOTION AND PARALLAX OF NOVA PERSEI.—In the *Astronomische Nachrichten* (No. 3834), Herr Asten Bergstrand details the observations he has made in order to determine the proper motion and the parallax of Nova Persei.

Using the astrographic refractors of the Upsala Observatory, Herr Bergstrand has obtained eighteen negatives of the Nova

region, and from ninety-five measurements of these negatives he has obtained the following values for the relative yearly motion of the Nova in regard to the comparison stars here given :—

Comparison Star.	Relative yearly motion of Nova. In R.A.	In Decl.
	"	"
a (B.D. + 43 730)	+0·06	±0·05
b (B.D. + 43·732)	−0·07	±0·07
c (B.D. + 43·748)	0·00	±0·07
d (B.D. + 43·751)	+0·10	±0·02

Herr Bergstrand has obtained $+0''.033$ as the final value for the absolute parallax of the Nova.

STAR WITH PROBABLE LARGE PROPER MOTION.—In making observations of Comet 1902 *b*, M. J. Pidoux, of Geneva, has found the position of the star B.D. $-1^{\circ}.3359$, relative to the position of the star B.D. $-1^{\circ}.3360$, to be $\Delta\alpha = -0s.\cdot03$ and $\Delta\delta = 10' \; 33''.6$. In the catalogue for 1855, these values are given as $-2s.\cdot4$ and $-12'.1$ respectively, thus showing—if the observations of M. Pidoux are confirmed —that the star has a large proper motion (*Astronomische Nachrichten*, No. 3834).

REPORT OF THE GOVERNMENT ASTRONOMER FOR NATAL, 1901.—This report deals with all the meteorological data collected during 1901 at the Government Observatory at Durban and at the thirty subsidiary meteorological stations which are scattered throughout the colony.

The equipment of the observatory has undergone no change during the year.

The table giving the yearly rainfall shows that the amount of rain which fell at Durban during 1901 was considerably above the average, being more than double the quantity recorded during 1900.

TOTAL ECLIPSE OF THE MOON, APRIL 22, 1902.—Several series of observations of this eclipse are recorded in this month's *Bulletin de la Société Astronomique de France*, and an excellent coloured plate, showing the appearance of the moon at various phases of the eclipse as seen by Dr. W. van der Gracht, of Graz (Styria), accompanies the observations made by him.

THE GREAT IRRIGATION DAM AT ASSUAN.

THE country of Egypt consisted principally in its natural state of level, arid plains with a few patches of vegetation on the higher parts. Its agricultural prosperity depends entirely on the irrigation derived from the River Nile. It is many thousands of years ago that the first attempt was made to regulate this river and make it serviceable to mankind. In the time of Menes, the west side of the river was embanked, and the water led by a system of canals and embankments to the land lying between the river and the Libyan mountains. When the river was in flood, openings were cut in the banks and the country converted into a series of lakes, the land being enriched and rendered fertile by the warp brought down in suspension by the turbid water of the river. When the floods subsided, the water drained off and the openings made in the banks were again filled up.

This system remained in existence until after the English occupation, when regulating sluices took the place of the more primitive method of cutting and making good the banks. A great depression on the Libyan side of the river was also, in the time of the Pharaohs, converted into a vast regulating basin known as Lake Mœris which was reckoned one of the wonders of the world. Afterwards the right side of the river was also embanked, and the channel enlarged and regulated.

To Joseph of scripture fame belongs the merit of having made one of the principal canals used for irrigating the land, and after the lapse of 4000 years the Bahr Usuf, or Joseph's waterway, is still doing useful work.

For records of further works of importance, it is necessary to skip over a very long period to the time of Mehemet Ali, about the year 1833, who, under the advice of French engineers, caused to be constructed the great barrage above Cairo across the Rosetta and Damietta branches of the Nile, and, by thus holding up the water when plentiful, a very large area of land is irrigated and rendered highly fertile during the dry period. When the difficulty and cost of obtaining the stone necessary for this great work was pointed out to the Egyptian ruler, it is said he at once gave orders for the destruction of so many of the pyramids as would provide the necessary material, and these monuments were only preserved by the engineers assuring the Khedive that the cost of this would be greater than transporting the stone from other places. Until the English occupation, this barrage was more or less a failure, as, owing to defective foundations, the water could not be held up sufficiently high to make the irrigation effective as it otherwise would be. When the English Irrigation Department obtained control over the works, this defect was with great skill and difficulty remedied.

It has long been recognised by the English irrigation engineers that the present system of irrigation very imperfectly makes use of the fertile properties of the Nile floods. The most perfectly irrigated lands command a rent equal to 5*l*. an acre ; imperfectly irrigated land is not worth more than 1*l*. an acre, while one-third of Egypt, or about two million acres, is yet undeveloped. It is estimated that the rental value of Egypt may be increased six millions a year by an effective system of irrigation. The great bulk of the land is dealt with by the original plan of basin irrigation, where the water is carried on to the land during the Nile floods and after remaining there for about six weeks is drained off. The more effective and profitable plan is where perennial irrigation is carried on, that is, where water can be supplied, not only in times of flood, but in summer and dry seasons. To effect this it becomes necessary to store up the water in floods in impounding reservoirs and let it out as required in the dry season.

The great dam at Assuan, which was opened with much ceremony in the presence of the Duke and Duchess of Connaught and the Khedive at the beginning of December, has been constructed for this purpose. This dam, erected across the Nile, will hold up the water for a distance of 147 miles.

For several years, the staff of the English Irrigation Department was engaged in surveying the country in order to arrive at the best site for the intended reservoir, and finally it was decided that the first cataract at Assuan offered the most eligible conditions for this purpose. A scheme designed by Mr. Wilcocks, the chief of the Engineering Department, was approved. This scheme was opposed because the Temple of Philæ would be submerged, and ultimately, in deference to the objections of archæologists and the foreign members of the International Commission who had to be consulted, a compromise was arrived at and the height of the dam was reduced, allowing the temple to stand out above the level of the water. The dam has, however, been so designed that at any future time the additional height can be added to it so as to take full advantage of the natural reservoir capacity. When this is done, ten millions of rental will be added to the resources of the country at a cost of about a quarter of a million a money.

The great dam is a Cyclopæan work. It is a mile and a quarter long, constructed of solid granite and cement, and is founded on the natural bed of granite over which the river runs. The height is 82 feet, and when full it will have a head of 65 feet of water against it. The base is 80 feet and the top 24 feet wide. It is pierced by 140 lower openings 23½ feet high by 6 feet wide, and 40 upper openings. These openings are provided by doors so hung and balanced that they can be lifted and lowered with very little labour. Through these openings, the Nile water will flow in floods and the scour will carry with it the sediment that may have settled when the water is still. As the flood waters decrease, the doors will be closed and the water impounded and only allowed to escape in such quantities as will be required for irrigation during the summer months. For the navigation, a canal a mile long has been cut through the rocks with a width of 50 feet, and a lock constructed having a descent of 69 feet in four drops.

For the further regulation of the water, another dam has been constructed across the Nile 330 miles lower down, above the entrance to the Ibrahimeh Canal at Assiout, to control the irrigation below this point. Here also a lock has been made of sufficient size to allow the largest steamers using the Nile to pass through.

When this scheme of irrigation was ripe for commencement, a question arose as to how the large sum of money required for its execution were to be raised. The International Commission charged with the finances of Egypt refused to allow a charge to be made on the public debt, and without this per-

mission the resources of Egypt were not equal to finding the money. In these circumstances, English enterprise came to the rescue. Sir Ernest Cassel, backed by a financial syndicate, undertook to find the money and Sir John Aird contracted to carry out the work. The capital fund is to be repaid by instalments of 166,000*l.* extending over thirty years, and it is anticipated that the irrigation will produce a revenue of 400,000*l.* a year. Sir Benjamin Baker has been the consulting engineer, and the work was carried out under the direction of Mr. Fitzmaurice, lately appointed engineer of the London County Council. The dam has thus been entirely carried out by English enterprise and English capital.

THE VELOCITY OF PROPAGATION OF X-RAYS.

M. R. BLONDLOT has recently made an experimental determination of the velocity of propagation of X-rays, as a result of which he finds that they travel with the same velocity as light. The full account of the work is published in the *Comptes rendus* for October 27 and November 3 and 10 (vol. cxxxv. pp. 666, 721 and 763), and a translation of the first two papers is given in the *Electrician* for November 21. As the subject is one of great importance, the following brief abstract of the methods used and the results obtained may be of interest to the readers of NATURE.

The method is based on a principle similar to that of Römer's method of determining the velocity of light. The arrangement of the apparatus is shown diagrammatically in Fig. 1. B and B′

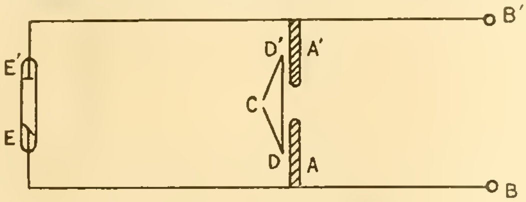

FIG. 1.—Diagram of M. Blondlot's apparatus.

represent the terminals of the secondary of an induction coil which are connected to the poles A, A′ of a Hertz radiator and to the electrodes E, E′ of an X-ray tube. Beneath the Hertz radiator is placed a resonator consisting of a copper wire folded into the shape of a triangle DD′C. The spark gap, C, of this resonator is so placed that it receives the X-rays from the focus tube, but is protected from all other radiation by screens of black paper and an aluminium plate. The oscillator AA′ consists of two brass cylinders arranged horizontally in a bottle of vaseline oil. By suitably altering the length of the spark gap, the oscillator and the focus tube can be made to work simultaneously. The action is then as follows:—At each current of break, the potential between E and E′ rises sufficiently for the X-ray tube to respond. As the potential continues to rise, a spark passes in the oscillator, and this, withdrawing energy from the focus tube, extinguishes it. By careful adjustment, the spark potential of the exciter can be made only slightly greater than the potential necessary to work the tube, in which case the tube will be extinguished very soon after the beginning of the oscillatory discharge, at the end of a time less than a quarter of the period of the radiator. The electric force at the resonator gap only reaches its maximum after a time equal to half the period of the oscillator; hence if the X-ray tube is close to the gap, the X-rays having been extinguished prior to this, there can be no action of the tube on the secondary spark. This conclusion is verified by interposing a sheet of lead between tube and gap, when it is found that the spark is not affected.

Now let the focus tube be kept in the same position and the wires AE and A′E′ be lengthened each by the same amount. This has the effect of delaying the extinction of the tube by the time required for the Hertzian waves to traverse this extra length of wire, and consequently the disappearance of the X-rays at the spark gap C is delayed by the same amount. The X-rays can, therefore, act upon the spark, and that they do so is shown by the fact that the interposition of a lead sheet now makes the spark less bright. If, on the other hand, the wires AE and A′E′ are kept of constant length and the tube moved farther away from the gap, then the X-rays will experience a retardation equal to the time they take to travel from the tube to the gap. The effect of moving the tube farther off should, therefore, be the same as that of lengthening the wires, and this is again confirmed by experiment; the spark grows brighter as the tube is moved away, but if a lead sheet be interposed, the brightness is unaffected by moving the tube. For a certain distance between tube and gap, the X-rays will have at the gap their full intensity during the whole of the time the potential at the gap has an appreciable value; at this point their effect is a maximum, for increasing the distance diminishes their intensity without increasing the time during which they and the electric force act together at the gap. This position of maximum can be found by experiment.

Let V and V′ be the rates of propagation in centimetres per second of the Hertzian waves and the X-rays respectively, and after determining the position of the tube giving the maximum spark when the connecting wires AE and A′E′ are of given length, let these wires be lengthened by α cm. The cessation of X-rays at the gap is thus retarded by α/V seconds. In order to re-establish the coincidence of the times and to find the new maximum, the tube must be moved nearer to the gap by a length β cm., such that $\beta/V' = \alpha/V$. The experiment gives β/α, and therefore V'/V. The following table gives the results of a series of experiments, the first column giving the values of α, the second and third columns the values of β as determined by M. Blondlot himself and his assistant, M. Virtz, respectively, and the fourth column the mean of these two values. Each of the numbers in columns 2 and 3 is the mean of five determinations.

α	β		
	Blondlot.	Virtz.	Mean.
− 7	− 5·9	− 6·5	− 6·2
9	10·5	8·9	9·7
12·5	12	12·6	12·3
15	15·1	14·5	14·8
25	25·3	24·5	24·9
30	31	30	30·5
40	39·3	39·6	39·4
25	24·6	23·2	23·9

The mean result of all the experiments in this and other series gives the value 0·97 for the ratio V'/V.

A variation of the method was also tried in which the ends of the resonator were separated by 0·3 cm., and two wires soldered to them and connected to a micrometer spark gap. These wires were bent back on themselves so as to bring the new gap into the same position as the old one. The Hertz waves have to traverse these wires before producing the spark, and if each wire is lengthened by a cm., the spark is retarded by a/V seconds. To obtain the new maximum, the tube must be moved away from the gap by a distance b cm. such that $b/V' = a/V$. A number of very concordant experiments by this method gave a mean value 0·93 for the ratio V'/V.

The final result of all the experiments, therefore, leads to the conclusion that *the velocity of propagation of X-rays is equal to that of Hertzian waves or of light through the air.* M. Blondlot concludes his papers by pointing out that this conclusion is in harmony either with the hypothesis that X-rays are radiations of very short wave-length or with that of E. Wiechert and Sir George Stokes, that they are electromagnetic impulses produced by the impact between the molecules or electrons in the kathode stream and the antikathode. The fact brought out by these experiments that the X-rays cease simultaneously with the current traversing the Crookes' tube, also supports the latter hypothesis.

MAURICE SOLOMON.

RECENT DIETARY STUDIES.

THE character of the daily menu is influenced by various considerations, but it will be universally conceded that the idiosyncrasies of the palate play the predominant part, and to suggest to the ordinary housekeeper that scientific principles should be allowed a voice in the determination of our diet would be simply to court ridicule, for of all departments of the household the kitchen is probably the most conservative in its customs and the most dominated by habit and tradition. It will not be

the fault of our Transatlantic cousins, however, if the reign of ignorance and indifference in this department of domestic life be permitted to continue, for the United States Board of Agriculture has recently published a series of bulletins or reports on the dietetic value of food stuffs of various kinds, embodying also the results of dietary studies on individuals carried out in all parts of the country.

These studies have not been confined to a particular class of persons, but have been undertaken in connection with the well-to-do as well as with the very poor, and embrace people engaged in hard physical work as well as those whose occupation is more sedentary in character; in fact, the common labourer and the average professional man are both represented in the types selected.

Of particular interest are the studies recorded of the dietary habits of the Chinese, for tradition assigns to this race the highest attainment in the art of producing from a given area the maximum amount of food material. This success is due firstly to a much more "intense" cultivation of the land than is customary in the western hemisphere, and secondly to the utilisation of a great variety of food plants, many of which are quite foreign to our culinary arts, but the employment of which enables the Chinaman to exploit every kind of soil and climate and compel it to yield up its quota of food material.

Thus a European visiting the Chinese market of San Francisco would have some difficulty in realising that the wares displayed were for culinary purposes, for amongst other garden plants he sees costly lily roots which he has been in the habit of importing at a high price with which to adorn his conservatories, here offered for sale as an attractive addition to the diner's menu. Many varieties of lily bulbs are eaten both by the Japanese and Chinese, but that principally on offer in the San Francisco Chinese market is the *L. brownii*. They are regarded as a delicacy and an especially desirable food for invalids, and are usually eaten but slightly cooked and with the addition of sugar. Chemical analysis shows the albuminoids present to be distinctly greater than in potatoes, but the most important constituent of the bulbs is starch, which is present in sufficient amount to endow them with a high nutritive value as a food stuff. But not only are the bulbs of lilies eaten; the dried flowers of the lovely day lily, *Hemerocallis fulva*, so sought after by all lovers of gardens on account of its rich colour and wealth of blossom, are largely used and highly prized by the Chinese as a flavouring ingredient. This article is sold under the name of "Kam cham t'soi" or the "gold-needle vegetable," and it has been found to possess a not inconsiderable nutritive value, besides being an attractive condiment.

Space does not permit of a reference to all the numerous and, to our ideas, strange articles which a Chinaman draws upon for dietetic purposes, but some mention must be made of the plant which both tradition and art have from time immemorial endowed with such a full measure of religious and classical associations.

To those of us who associate the *Nelumbium speciosum* of the botanist with the "mild-eyed, melancholy lotus eater," of the poet "whose voice was thin as voices from the grave," whilst "deep asleep he seemed yet all awake," the extensive economic use to which the lotus plant is put comes as a surprise. Whilst sought after on account of its surpassing beauty and grown in some parts in great vases placed at the doors of the houses, its more material applications are both numerous and varied. Thus we read, in a report published by Jules Grisard in 1896, that the stamens are used in China as an astringent remedy and also for the toilet; the petioles and peduncles furnish a viscous sap employed in India as a remedy for vomiting and diarrhœa; the fibro-vascular bundles of the petioles are made into lamp wicks, and the carpophore furnish a popular remedy for blood spitting. The seeds are eaten either raw, boiled or roasted, much as we use chestnuts, but the dark green germ is very bitter and is removed before use, and has given rise to the Chinese saying "bitter as the plumule of the lotus seed." A kind of bread is made of the seeds in Egypt, whilst they are also used as a remedy for indigestion, &c. Starch is extracted from the roots which is highly prized for its reputed strengthening properties; but this does not by any means exhaust all the virtues attributed to this wonderful plant. The Chinese materia medica, however, is said to present too many incongruities to permit of implicit reliance being placed upon the numerous medicinal properties associated with it, but the roots are on sale in considerable quantities, Mr Blasdale informs us in his report, throughout the winter and early spring months in the Chinese market of San Francisco.

It is popularly supposed that the Chinese live almost entirely upon rice and that their diet is limited in amount, the apostles of vegetarianism not infrequently quoting the Chinaman as an example of how large an amount of hard work can be accomplished on a vegetarian diet. Studies, however, made in the Chinese quarter of San Francisco[1] do not support this theory, but show that whilst much more varied than that of an American or European, the Chinese diet is neither scanty in amount nor inferior in nutritive quality, whilst it is decidedly more varied and far cheaper than that of the former.

Thus, in the dietary study of a Chinese dentist's family living in comfortable circumstances and fairly typical of the average Chinese professional man, it was found that whilst the total amount of nutrient actually consumed per man per day agreed very closely with that suggested, as the result of inquiry, as a standard for a man engaged upon light muscular work, viz. 112 grams protein and 3150 calories of energy, the cost per man per day in the case of the Chinaman's family was about 50 per cent. less than that which experience has shown to be the average expenditure in the family of a professional man of the same position in the United States.

On inquiring more closely into the nature of the diet of this Chinese family, we find that as regards the source of animal protein pork took the first place, supplying nearly one-third of the total; fish comes next, followed by chicken, and last on the list is beef. The main vegetable food was rice, but considerable quantities of bread and other cereal products were also used, and a large amount of cheap green vegetables, the greater part of the latter being Chinese varieties. Amongst the unfamiliar articles of food recorded were dried crabs, dried shrimps, dried radishes, taro root, bean sprouts, bean cheese, dried fungus, lily petals, algæ, bamboo shoots and the leprosy gourd. Tea and coffee were used as beverages, and the daily expenditure per head for these was 0·5 cent.

Dietary studies of Chinese engaged upon hard physical labour such as prevails on a Chinese truck farm or vegetable garden, again, showed that the diet adopted furnished very nearly the amount of animal protein and calories of energy commonly accepted as the standard of that required by a man in active work, *i.e.* 150 grams protein and 4500 calories. In this case also the diet was very varied, and we find included among the peculiarly Chinese articles of food water-lily roots, dried lily flowers, water chestnuts, bean cheese, dried fungus, &c. The cost per head per day was 19·7 cents, and Prof. Jaffa, who furnishes the report on these Chinese diet studies, says that as regards the Chinaman's capability for work there is no question: "few Americans could walk as he does for hours at a stretch, often up and down hill, burdened with a load of from 300 to 400 pounds in the baskets which he carries suspended by ropes to a pole balanced across one shoulder, whilst in adverse circumstances, such as long hours, great heat or exposure to cold and dampness, a Chinaman can not only do more work, but can stand the strain better than a strong white man."

Let us now turn to some of the dietary studies made in New York city amongst the poorer classes and reported by Messrs. Atwater and Woods. The district selected is described as "one of the worst congested and typical of the portions of the city known as slums," whilst the families selected for dietary study were chosen as representative of the population of the district. The diet of no less than twenty-one different families over a period of ten days was carefully recorded, and the results obtained are of much economic importance, showing that in many cases unwise expenditure is fully as responsible for distress as a too limited income.

As an instance of this the case of a mechanic's family in very poor circumstances may be cited. This family had received a great deal of help from the Association for the Improvement of the Condition of the Poor, and yet it was found that the expenditure on food was nearly twice that per head in the family of a well-to-do professional man, hardly anything being left over from the wages earned for fuel, lights, clothing and the many other requirements of a family. The food consumed furnished at least 25 grams of protein and 600 calories of energy per head in excess of that required by a man at moderate work. Whilst the amount of food purchased could have been reduced 25 to 30 per cent., a more judicious selection of the same and more skill in its preparation would have enabled a

[1] From inquiries it was ascertained that the system of diet adopted by the Chinese in San Francisco differs but little from that of the Chinese in their own country.

large proportion of the money spent on food to have been expended on other things.

What applies to this family applies equally to many of the other families in which dietary studies were carried out, and over and over again we find it stated that more food was purchased than was necessary for efficient nourishment. To each dietary study is appended criticisms of and suggestions for changes and improvement in the diet pursued, and these constitute a valuable addition to the report and form, indeed, an eloquent argument that our school curriculum should provide for the education of children in the elementary principles of diet in relation, not only to the economy of the body, but also to that of the family purse.

The selection of food stuffs on rational or scientific principles does not, perhaps, sound appetising, but the numerous investigations on the nutritive value attaching to substances which have been carried out in America and elsewhere cannot be overlooked, and it is, perhaps, not unreasonable to believe that current notions on diet may become modified in the future, more especially in those cases where on economical grounds reform is so urgently needed. These studies are, therefore, of social as well as scientific importance, and acquire particular significance for the poor at times when taxes shall tell heavily upon their resources.

In conclusion, brief reference may be made to the elaborate experiments which have been carried out on the different degrees of waste entailed in the different methods adopted for the cooking of food of various kinds.

Amongst the names associated with investigations on the loss of nutrients in the cooking of meat, we find that of Thudicum in this country, Vogel and König in Germany, whilst in America the most recent contributions to this subject have been made by Grindley, in conjunction with Messrs. McCormack and Porter. As regards the loss in weight which takes place, various investigators agree in stating it to be from one-fifth to one-third, whether the meat be boiled or roasted. Where beef, for example, is cooked in water, from 3 to 20 per cent. of the total solids is found in the resulting broth, the degree of loss in constituents appearing, to a certain extent, to depend upon the size of the piece of meat employed, the smaller the dimension it is reduced to the greater being the loss; whilst the duration of time of cooking must also be taken into consideration, the more prolonged it is the greater, again, being the loss entailed. The practical lesson to be learnt from the investigations which have so far been made appears to be that the most economical method of cooking meat is to broil it in a frying-pan, for in this manner the least loss of nutrients occurs.

In the case of vegetables, the losses entailed by cooking appear to be even greater than those recorded for meat. Thus as regards carrots, in boiling them nearly one-half of the mineral matters present are lost, together with about 40 per cent. of the total nitrogen and about 26 per cent. of the sugar present.

These percentages of loss or waste may be considerably reduced if the carrot is boiled whole instead of being first cut, as is customary, into small pieces. In this manner the loss in sugar, for example, instead of being 26 per cent., is reduced to very nearly half that amount, and similar economies may be effected in regard to the other constituents of the carrot.

In boiling cabbages the loss is very considerable, from 35 to 40 per cent. of the total nitrogenous matter present being left in the water, which, as everyone knows, is consigned to the kitchen sink as rapidly as possible. The Scotch recipe for making broth, which involves the addition of uncooked cabbage to the stock-pot, besides being justly renowned for the excellent results it produces, has also, therefore, distinct advantages from an economic point of view. As regards potatoes, we cannot do better than follow the custom of cooking them which prevails in the Emerald Isle. The Irish method of boiling potatoes in their skins is not only the most palatable, but also the most economical way of using them, for when potatoes are peeled and then boiled there is a very considerable loss, not only of organic nutrients, but also of the mineral salts present.

The above brief review may help to emphasise the economic importance quite apart from the scientific interest attaching to such investigations, for by indicating, not only the best means of utilising the existing sources of food supply, but also for extending their range, such researches may conceivably contribute not a little to the prosperity of a country as a whole, whilst they can undoubtedly promote the well being and to a certain extent, therefore, the happiness of the individual.

G. C. FRANKLAND.

MAGNETIC OBSERVATIONS IN BADEN.

AN account of a minute magnetic survey of a small district in Baden, adjacent to the Rhine, where there is considerable local magnetic disturbance, has been received from the author.[1] Observations of horizontal force were made at nearly 400 stations, and observations of declination and inclination were made at about 140 of them. The object seems to have been to observe at a large number of stations with moderate accuracy in a short time. In fact, most of the data recorded in the tables on pp. 6–26 seem to have been obtained in the two months August and September of 1898. Horizontal force was observed only to the nearest 0·001 C.G.S., and declination and inclination usually only to the nearest 0°·1. Within the narrow region dealt with—some 150 square kilometres—declination was observed to vary between 3°·7 W. and 20°·8 W., inclination between 56°·6 and 72°·0, and horizontal force between 0·173 and 0·227 C.G.S. In a district so disturbed, it would have been of doubtful advantage to have employed superior instruments, giving a higher order of accuracy than that actually aimed at. The results are embodied in four charts, which give respectively the lines of equal horizontal force, the isoclinals, the isogonals, and particulars of the horizontal and vertical components of the disturbing force system. The chief conclusions appear on p. 39. The most interesting of them is that the basaltic rocks—using *basaltic* in a general sense—which form the chief hills in the district, behave mostly like vertical magnets with their north poles uppermost. Their magnetisation is thus *opposite* to what it would be if induced under the action of the earth's own field. The phenomena thus differ in a remarkable way from those observed by Rücker and Thorpe in the United Kingdom. A second somewhat interesting deduction from the observations is that there is an extension of underground basaltic masses beneath part of the level country adjacent to the Rhine near Breisach, where local disturbances would not have been anticipated from the superficial appearance of the country. The author also gives the results obtained from taking a line integral of the horizontal magnetic force round the whole district and round four subdivisions. With the exception of one of the smaller subdivisions, the departure of the line integrals from zero is very small. This may be regarded as evidence of the accuracy of the observations, if we assume that the magnetic forces are derivable from a potential, which can hardly fail to be the case so far as concerns the field answering to the local disturbances. C. C.

THE ORIGIN OF THE THOROUGHBRED HORSE.[2]

THE author said that he had shown (*Academy*, January, 1891, p. 91) that not only, as had been long observed, did the Homeric Greeks drive the horse before they rode him, but that the same was true of all ancient peoples—Egyptians, Canaanites, Assyrians, Aryans of Rig-Veda, Umbrians, Celts—and that the explanation of this was given by Herodotus (v. 9), who, in speaking of the Sigynnæ, the only tribe north of the Danube, whose name he knew, said that they had small horses, with large flat noses and very long hair, which, though not able to carry a man, were excellent under chariots: "wherefore they used chariots." Dio Cassius likewise says that the Britons used chariots in war, because their horses were "small though active." The description of the horses of the Sigynnæ tallies exactly with the abundant remains of the primitive horse of Europe, eaten in great quantities and delineated on antlers by the men of the Stone Age. He was a small animal about 10 hands high with a big head. Even after domestication he remained very small, as witness bits of bronze and horn found in Swiss lake dwellings, the shoes found at Silchester, and in camps on the Roman Wall, &c. Authorities are agreed that from this primitive horse has been developed the cart horses of the continent and these islands, whilst our blood horses have come from an eastern stock of slight build and smart appearance. Our problem is to ascertain the original habitat of this superior horse. He has not come from upper Asia, as the Mongolian pony is taken as the type of the coarse, thickset horse from which sprang the cart horse. The Mongolian pony probably

[1] "Erdmagnetische Untersuchungen im Kaiserstuhl." Von Dr. G. Meyer. Mit 4 Karten. (Separatabdruck aus den Berichten der Naturforschenden Gesellschaft zu Freiburg i. B. Bd. xii., 1902.)

[2] Abstract of paper read before the Cambridge Philosophical Society on November 24, by Prof. Ridgeway.

represents the Scythian horses, which continued to be of a small size down to Strabo's time, and they were derived either from he tarpan or Prezevalsky's horse. The Mongolian pony, though surefooted and enduring, is slow of pace. Neither China, Siam nor Burmah have any indigenous horse answering to the blood horse. India could never breed horses, says Marco Polo, in whose time India was supplied either with Mongolian ponies from Yunnan or with Arabs from south Persia, Aden and other Arabian ports. These Arabs fetched enormous prices, equivalent to 200*l.* It has hitherto been universally held that Arabia is the original home of the blood horse. This is a baseless assumption. In the Old Testament, the Arabs are never mentioned as riding anything but camels and asses. Though the author of Job knew of the war horse, yet Job did not own a single horse, his equine possessions consisting of 500 she asses. Herodotus (vii. 87) enumerates the nations (including the Libyans) that supplied cavalry to Xerxes' host, but the Arabs only furnish a camel corps. Agatharchides (cited by Strabo) describes the Arabs as camel keepers.

Finally, Strabo (*flor.* A.D. 1) expressly states that neither the peoples of Arabia Felix nor those of Arabia Petræa bred horses. Naturally, then, Scaurus after defeating the Arab king Aretas put on his coins Aretas leading his camel. It is clear, then, that down to the Christian era the Arabs bred no horses. It is therefore clear that though the Persian kings in the fifth century B.C. bred the largest and best horses in Asia, these were not of an Arab strain. These horses were kept largely in Armenia, and are described by Strabo as similar to the Parthian horses, and as differing from the horses bred in Greece and the other kinds of horses known in the Roman empire. There can be little doubt that they were the same horses as Marco Polo found in great numbers in Armenia (1270 A.D.) known as Turquans, the Turcoman ponies well known in Persia to-day. The Persian horses cannot, then, have been the ancestors of the thoroughbred, though it is quite possible that their superiority was due to their having a cross of thoroughbred blood, for already by 900 B.C. Solomon imported horses from Egypt (1 Kings x.), and "so for all the kings of Syria and for all the kings of the Hittites" Egypt could not breed horses, neither could she have got them from the Arabs, who bred none even 1000 years later. But she could and did get them from the Libyans, who from the dawn of history are masters of the most famous horses. Cyrene sent the best horses to the games of Greece (Pindar, *Pyth.* iv., &c.). It is noteworthy that it was in the same century as the founding of Cyrene that the four-horse chariot and the racehorse were added to the Olympic events. The Phœnician settlers at Carthage found the Libyans using these beautiful horses, and when they struck coins placed a horse or a horse-head on them as the badge of Libya, and used a similar type on their coins struck in Sicily, whither, doubtless, they carried the Libyan breed. This accounts for the extraordinary fame of the horses of Etna and Syracuse and the famous steeds of Tarentum. It is now clear that the Arabs never owned a good horse until they had become masters of North Africa and the Barbary horses, from whom are sprung our own racing stock through Lord Godolphin's Barb. North Africa, therefore, and not Arabia or any other part of Asia is the original home of the thoroughbred.

Now, though the pedigree of the cart-horse type can be traced to the coarse, thickset little horses of Europe and Asia, the wild ancestor of the Barb is yet to seek, for Africa has no wild horse, such as tarpan or Prezevalsky's, though she has an ass and four zebras, including the quagga, now extinct. Can the Barb be sprung wholly or in part from a zebra? Arab foals at birth constantly have zebra markings, sometimes retained when full grown, as by Prof. Ewart's Arab filly Fatima. Strabo, too, notices that the horses of the Libyan Garamantes have longer hoofs than any other horses. Prof. Ewart's hybrids from Burchell's zebra and various mares show the markings, not of a Burchell's zebra, but of a Somaliland zebra, from which it has been inferred that the remote ancestor of both *Equus caballus* and Burchell's zebra was striped like the Somaliland and mountain zebra. But is it necessary to go back so far? May not the Somaliland zebra stripes in the hybrid be due to the circumstance that the dam in each case had a certain amount of Barb blood in her, which was derived from either the Somaliland zebra or a closely allied species? He (Prof. Ridgeway) had crossed a Muscovy drake with a common white duck, derived from the common wild duck, with the result that all the offspring are coloured, and their colouring resembles that of the mallard. No one would say that the hybrids show a reversion to a remote common ancestor of both mallard and Muscovy, for it is obvious that the colouring is simply that of the white duck's immediate ancestors. Authorities like Captain Hayes have pointed out the great similarity in form between Burchell's and the Somaliland zebra to a well-bred horse, *i.e.* a horse that has Barb blood in him. He therefore suggested that the Barbary horse, from which he had shown all the fine horses of the world have sprung, was derived either from the zebra of north-east Africa or, as is more likely, from some very closely allied species, now extinct, which, like Prezevalsky's horse, may have had castors on its hind legs like *Equus caballus*.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Mr. A. S. Green has been appointed professor of dyeing at Yorkshire College, in succession to the late Prof. Hummel.

The University of California is about, says *Science*, to erect a physiological laboratory at a cost of 25,000 dollars. It will be under the charge of Dr. Jacques Loeb.

The royal assent was given to the Education Act, 1902, on Thursday last. The Act comes into operation, except as expressly provided, on March 26, 1903, or such other day, not being more than eighteen months later, as the Board of Education may appoint. The Act does not extend to Scotland or Ireland, or for the present to London.

Bedford College for Women, London, and the Sanitary Institute have in conjunction arranged a conference on the subject of hygiene for schools, to be held at the College on January 21, 1903. Prof. C. S. Sherrington, F.R.S., Dr. Gow, Mr. Michael Sadler, Prof. Adams and others are expected to speak. Further particulars and cards of admission can be obtained either from the Sanitary Institute or from Bedford College.

The special committee appointed to consider the needs of South Africa in regard to technical education, with special reference to the Transvaal, have, says the *Chemist and Druggist*, submitted a lengthy report, and state they are convinced that there is a great demand, especially in Johannesburg, for technical education. This demand can best be met, in their opinion, by establishing an institution providing the highest kind of training in arts and sciences. They recommend that all students, before admission to the institution, pass an examination of a standard equal to the matriculation of the Cape University. Complete courses should be provided in the new institution, the committee think, in mining, mechanical and electrical engineering, metallurgy and chemical engineering, civil and sanitary engineering, and architecture.

In his paper on French rural education, read before the Society of Arts on December 10, Mr. Cloudesley Brereton explained the part taken by the primary and secondary schools in the agricultural education of the nation. In France, in some communes, one person in every four is a land proprietor, and the aim in the primary schools has been to give the pupil some grasp of the principles underlying the science of agriculture. The teacher is not so much supposed to follow implicitly the departmental programme, but rather to choose those portions which best suit his own particular district. There is still doubt in the minds of French educational authorities whether the scientific or the agricultural side of the instruction should predominate in the instruction given in primary schools. The teachers in these schools are themselves trained by professors of agriculture in the training colleges, and though the course of instruction is a good one, it might with advantage be more practical. In the secondary schools of France, agricultural education has an insignificant place, but the work done in this direction by means of lectures and evening classes carried on in connection with old boys' clubs and other organisations is very great.

An important article, by Mr. W. M. Webb, on the progress and interpretation of "nature-knowledge," especially in relation to the experience gained at the Nature-Study Exhibition held last August in London, appears in the October issue of the *Record of Technical and Secondary Education*. After referring

to the importance of nature-study as a factor in the new education, the author insists on its value as a means of cultivating the powers of observation and at the same time warns his readers that it is not to be considered as in any way identical with elementary science. Various definitions and limitations of the subject are then given, after which attention is directed to its aims and objects. Among these, stress is laid on its power of interesting pupils—especially those to whom the ordinary school-curriculum is peculiarly distasteful—and thus rendering education a pleasure rather than a toil. It is also urged that nature-study promises to be the form of education best adapted to develop the pupils into good citizens capable of making their way in the world and, above all, of relying on their own judgment. Healthful it certainly is, and the love of nature it engenders may, it is suggested, tend to check the exodus of the population from the country to the towns. The difficulty of securing the right class of teachers claims a considerable share of attention, and some amount of discussion is devoted to the question as to the extent to which books should be used. Collecting, again, is a phase of the subject which requires very careful treatment in order to prevent the pupils from degenerating into mere curiosity-hunters. The author is, however, of opinion that both books and collections have their place in the scheme. The relative values of outdoor and indoor work are then discussed, in the course of which much importance is attached to the "seasonal method" of study. Before the final summary, the article winds up with observations on teachers of all grades and classes, and the best method of training them, followed by a reference to the objections against, and the difficulties connected with, "nature-study."

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 27.—"The Inter-relationship of Variola and Vaccinia." By S. Monckton Copeman, M.A., M.D. Cantab., F.R.C.P. Communicated by Lord Lister, F.R.S.

The term "variolæ vaccinæ" employed by Jenner, as a synonym for cow-pox, has been generally accepted as affording evidence that, in so naming this disease "small-pox of the cow," he was desirous of placing on record his belief that cow-pox or vaccinia was intimately related to human small-pox, if indeed it were not directly derived from it.

But the difficulty experienced by the writer and numerous other investigators in attempts to transmit small-pox to bovines, whether cows or calves, has not infrequently been cited as a reason for regarding Jenner's theory with distrust.

It is well known, however, that a great deal, at any rate, of the small-pox which was prevalent at the time that Jenner lived and wrote was of that comparatively mild variety which, under the name of inoculated small-pox, was intentionally produced in healthy subjects, with the object of thereby conferring protection against subsequent attack by the disease in virulent form.

So mild indeed, at times, were the results of inoculations in the hands of such operators as Adams and the brothers Sutton, that, as we learn from contemporary records, in many instances but little obvious effect was observed, with the exception of the local vesicle arising at the site of insertion of the small-pox virus. The majority of persons thus inoculated are not likely, therefore, to have been incapacitated, as the result of the operation, to a much greater extent than are those who undergo efficient vaccination at the present day, and, doubtless, they would be, for the most part, capable of following their ordinary avocations during the progress of the induced disorder.

Not only were the effects following on inoculation comparatively mild, but the disease in this form was intentionally carried into many country districts which otherwise might not have become invaded by small-pox.

In the light of these facts, it would appear not improbable that it was from the *inoculated* form of small-pox rather than from the ordinary variety of the malady that much, at any rate, of the cow-pox in the pre-vaccination era was derived. Supposing this to have been the case, it is not difficult to understand how that the cracks, so often found on the udders of cows, might become infected by a milker with fingers contaminated by contact with the inoculation sore upon his arm.

In default of inoculated small-pox in the human subject, use was made of the monkey, which, as the writer had shown in a previous communication to the Royal Society, is readily susceptible to the disease. The necessary small-pox material has been obtained during the course of recent outbreaks of small-pox at Middlesbrough, Glasgow and London.

The results of the experiments may be briefly summarised as follows:—In each of the separate series, the human small-pox lymph or pulp was first inoculated directly on calves, and in every instance, so far as could be observed, with altogether negative results. But with monkeys, success was as invariably obtained, and when, after one or more passages through this animal, the contents of the local inoculation vesicles were employed for insertion on the calf, an effect was now produced which, after two or three removes in that animal, was indistinguishable from typical vaccinia. Moreover, from the contents of vesicles raised in this manner on the calf, a number of children have been vaccinated, some of whom were afterwards kept under observation for a considerable period. Every such vaccination "took" normally, and in no case was any bad result subsequently observed.

The experimental results obtained all tend, then, to confirm the view that the vaccinia of Jenner's time was derived, in all probability, from a comparatively mild form of small-pox. Of even more importance is the fact that the work has afforded conclusive evidence of the essential identity of the virus of small-pox and cow-pox or vaccinia.

December 4.—"On the Vibrations and Stability of a Gravitating Planet" By J. H. Jeans, B.A., Isaac Newton Student and Fellow of Trinity College, Cambridge. Communicated by Prof. G. H. Darwin, F.R.S.

The first part of the paper deals with the vibrations and stability of a gravitating elastic sphere. The matter is not necessarily homogeneous, but is arranged in spherical layers. It is pointed out that, in the classical investigation of the displacements produced in a gravitating sphere by given surface-forces, the most important of the gravitational terms is omitted. The effect of this omission is to necessitate a correction, and this may entirely invalidate the solution when we are dealing with spheres of the size of the earth or other planets. In fact, it appears that for a gravitating solid of the kind we are discussing the spherical configuration may be one of *unstable equilibrium*, the instability being brought about by these gravitational terms. The vibration through which instability first enters is one in which the displacement at every point is proportional to a harmonic of the *first* order.

In a former paper, "The Stability of a Spherical Nebula" (*Phil. Trans.*, A, vol. cxcix., p. 1), the suggestion was put forward that the instability of a nebula, sun or planet, which, upon the nebular hypothesis, is supposed ultimately to result in the ejection of a satellite, may be largely brought about by a gravitational tendency to instability of the kind described. We take, for the moment, an extreme hypothesis, and imagine that this agency is the preponderating agency and that the rotational tendency to instability may be disregarded in comparison.

Except for the changes which have occurred since the consolidation of the planets, the solar system supplies material for testing the consequences of this hypothesis. When a number of planets of varying masses have thrown off satellites, we find (upon our present extreme hypothesis) that the masses ought to be proportional to the *squares* of the radii. It is found that this law is approximately obeyed in the solar system. It is further found that the absolute values of the masses and radii are approximately such as would be expected.

It is interesting to compare two extreme hypotheses, the first referring the phenomena of planetary evolution solely to rotational, the second solely to gravitational, instability. Given the approximate values of the density and elasticity of a planet, and the fact that this planet has thrown off a satellite, then the former hypothesis leads to a certain inference as to the angular momentum of the system, the latter to an inference as to the radius of the primary. The former leads to no inference at all as to the size of planets which are to be expected—they are as likely to be of the size of billiard balls as of the size of the planets of our system—while the latter leads to no inference as to the angular momentum of the system, but presupposes it to be small. The contention of the present paper is that the inferences which are drawn from the former hypothesis are not borne out by observation on the planets of our system, while those which are drawn from the latter are borne out as closely as could be expected. The true hypothesis must of necessity lie somewhere between the two extremes which are being

compared, but the evidence seems to show that it is much nearer to the latter (gravitational) than to the former (rotational).

We next consider a number of questions connected with the figure of the earth. It seems to be almost certain that the present elastic constants of the earth are such that a state of spherical symmetry would be one of stable equilibrium. On the other hand, if we look backwards through the history of our planet, we probably come to a time when the rigidity was so small that the stable configuration of equilibrium would be unsymmetrical. At this time the earth would be pear-shaped, and the transition to the present approximately spherical form would take place through a series of ruptures. It is suggested that the earth, in spite of this series of ruptures, still retains traces of a pear-shaped configuration. Such a configuration would possess a single axis of symmetry, and this, it is suggested, is an axis which meets the earth's surface somewhere in the neighbourhood of England (or possibly some hundreds of miles to the south-west of England). Starting from England, we find that England is at the centre of a hemisphere which is practically all land; this would be the blunt end of our pear. Bounding the hemisphere we have a great circle, of which England is the pole, and it is over this circle that earthquakes and volcanoes are of most frequent occurrence. Now, if we suppose our pear contracting to a spherical shape, we notice that it would probably be in the neighbourhood of its equator that the changes in curvature and the relative displacements would be greatest, and hence we should expect to find earthquakes and volcanoes in greatest numbers near to this circle. Passing still further from England, we come to a great region of deep seas—the Pacific, South Atlantic and Indian oceans; these may mark the place where the "waist" of the pear occurred. Lastly, we come, almost at the antipodes of England, to the Australian continent. This may mark the remains of the stalk-end of the pear.

Physical Society, December 12.—Mr. S. Lupton, vice-president, in the chair.—Mr. S. W. J. Smith exhibited and described a portable capillary electrometer. This instrument is a modification of the form of capillary electrometer which consists of two wide tubes joined by a cylindrical capillary tube which may be horizontal or inclined. The apparatus contains mercury and sulphuric acid of about maximum conductivity suitably distributed in the tubes. A spring key is commonly used with the instrument, but the author has devised a key consisting of a U-tube closed at one end, communicating at the other with a pneumatic pressure ball and containing mercury in the bend. By squeezing the ball, the same change of contacts can be produced as by pressing the lever of an ordinary spring key. Using this key and a microscope magnifying 50 diameters, a potential difference of 1/10,000th volt can be detected without difficulty. The instrument, used as a surface-tension galvanometer, is more convenient than an ordinary galvanometer with a magnetic system because there is no suspension, no lamp and scale, and practically no levelling.—A paper on astigmatic aberration was read by Mr. R. J. Sowter. This paper affords a simple explanation of some of the shadow phenomena observed by Prof. S. P. Thompson in his experimental researches on the aberration of lenses, namely, in those experiments in which the aberration is wholly or in part astigmatic.—Prof. L. R. Wilberforce exhibited apparatus for a lecture experiment on gaseous diffusion. In Graham's experiments on diffusion through porous septa, the gas experimented upon was contained in a vessel inverted over water, and the pressure was kept approximately atmospheric by applying a counterpoise to the vessel. This adjustment, however, is imperfect owing to the weight of the water displaced by the material of the vessel. Prof. Wilberforce showed that, by suspending the vessel from one arm of a balance rendered suitably unstable by a weight above the central knife-edge, a compensating effect could be introduced and the pressure kept sensibly constant for a considerable range of motion of the vessel. He pointed out that this device could also be utilised for the measurement of pressure.—A paper on vapour-density determinations, by Sir W. Ramsay and Dr. Steele, was read by Sir W. Ramsay. This paper gives a detailed account of some accurate experiments on the densities of vapours over a large range of pressure carried out by a modification of Gay-Lussac's method. This method has the advantage that while densities are being determined, compressibilities can, within certain limits, be simultaneously estimated with the same sample of material. From results of experiments, it appears that the densities of certain compounds calculated for zero pressure are not proportional to their molecular weights deduced from the atomic weights of the elements which they contain. This conclusion involves one, or it may be several, of a series of assumptions enumerated in the paper. These assumptions are fully investigated and discussed, and the authors suggest that it may be possible that the atomic weights of the elements depend on the proportion in which they are present in the compounds which contain them.

Royal Astronomical Society, December 12.—Dr. J. W. L. Glaisher, F.R.S., president, in the chair.—Mr. Innes presented a paper on some developments in terms of the mean anomaly and also the results of measures of double stars made at the Royal Observatory, Cape of Good Hope, in 1902. He made some remarks on the excellence of the McClean telescope, with which the measures were made, and the great convenience of the rising floor of the observatory.—Mr. Hardcastle read a note on binding together réseaux and plates. In measuring some photographs of the moon, on which no réseau had been impressed, the réseau plate and photograph were bound together film to film, but in the course of measurement a slight shifting occurred, which it was difficult to prevent. —Mr. Bellamy read a note on preserving negatives. Some developed star negatives which had been placed in envelopes and stacked on shelves were found after a time to have received on the film a faint image of the inscription that had been written on the envelopes. Mr. Knobel remarked that this was certainly not due to the effect described by Prof. Russell, as the writing was only visible on the film by reflected light.—The Astronomer Royal exhibited and described a new measuring machine which had been made by Troughton and Simms for the Royal Observatory, Greenwich, and was intended for the measurement of photographs of Eros.—A paper by Mr. Robinson, of the Radcliffe Observatory, Oxford, was read, on the photographic and visual magnitude of α Orionis. Between March 9, 1901, and October 22, 1902, the photographic magnitude of this star had slightly increased, and since the latter date there appeared a gradual decline in brightness; both the increase and decrease were confirmed by the visual estimations.—Photographs of the spectra of Jupiter, Saturn and other planets, taken by Mr. Percival Lowell at Flagstaff, Arizona, were shown on the screen.—Mr. Hinks exhibited photographs of Mr. Ritchey's series of drawings from the negatives of the nebula surrounding Nova Persei taken at the Yerkes Observatory. Mr. Hinks showed by the aid of diagrams how the apparent motion of the nebula might be explained upon the hypothesis of Prof. Kapteyn, that successive portions of the nebula were illuminated by the star and that there was no real motion of the nebula itself.

Mathematical Society, December 11.—Prof. Lamb, president, in the chair.—The following papers were communicated:—Prof. L. E. Dickson, (1) The abstract group simply isomorphic with the group of linear fractional transformations in a Galois field; (2) Generational relations of an abstract simple group of order 4080. The first paper deals with the abstract group of order $\frac{1}{2}p^n(p^{2n}-1)$, which is simply isomorphic with the group of all linear fractional transformations on one variable, with coefficients belonging to the Galois field $[p^n]$, and with determinants equal to unity. It is shown that when $n=1$, the group may be generated by two operations which are subject to generational relations, and these relations are determined. When n has other values, the generating operations are more numerous, but the generational relations are again determined. The validity of the theorems depends in general on the solution of a problem in the theory of numbers, which can be treated readily in any particular case. In the first paper, p is supposed to be greater than 2; the second paper deals with the case $p=2$. —Dr. H. F. Baker, (1) On the calculation of the finite equations of a continuous group; (2) On the integration of linear differential equations; (3) On some cases of matrices with linear invariant factors. In the second paper, use is made of the matrix notation for the systematic study of linear differential equations. This study leads to two independent problems. One problem consists in the determination of all irreducible types of multiplication tables of sets of matrices of the same order, a problem akin to that of the enumeration of types of discontinuous groups. The other problem consists in the investigation of the properties of a class of functions which arise by repeated integrations from simpler functions. The serial solutions which are obtained converge for all finite values of the

independent variable in a suitably chosen "star-region," and their character near the corners of the region is determined. The work is applied to elucidate the connection between the form of the system of linear equations and the form of the linear substitutions, by which the monodromy group of the system is generated. The results are exemplified by the study of particular equations of the hypergeometric type.—Prof. M. J. M. Hill, The continuation of the power series for arc sin x.—Mr. E. T. Whittaker, The functions associated with the parabolic cylinder in harmonic analysis.—Mr. H. M. Macdonald, Some applications of Fourier's theorem. The expression of an arbitrary function by means of Fourier's theorem is thrown into the form of a double integral, the path of integration with respect to one variable being part of the axis of real numbers, and the path with respect to the other variable going to ∞ in the two senses of the axis of imaginary numbers. The theorem is generalised by altering the latter path of integration, and the generalised form is applied to the evaluation of certain integrals involving Bessel functions. Numerous properties of these functions are deduced.—Rev. F. H. Jackson, Series connected with the enumeration of partitions.—Mr. W. H. Young, Sets of intervals, part ii., overlapping intervals. In the present paper, some of the methods and results of a previous paper by the same author are applied to the case of overlapping intervals on the straight line. In this way, direct proofs are obtained of a theorem in the theory of aggregates due to Heine and Borel, and of its so-called counterpart. Certain restrictions in the usual enunciation of these theorems are shown to be unnecessary.—Mr. G. H. Hardy, On the expression of the double Zeta and Gamma functions in terms of elliptic functions. The logarithms of the functions studied by Barnes (*Phil. Trans.* Roy. Soc., Ser. A, vol. cxcvi., 1901) are expressed by means of definite integrals involving the Weierstrassian elliptic and Zeta functions.—Mr. J. H. Grace, Perpetuants (second paper).

Royal Microscopical Society, November 19.—Dr. Hy. Woodward, F.R.S., president, in the chair.—Dr. D. H. Scott, F.R.S., gave a demonstration on the microscope in fossil botany. After giving a brief history of the subject from 1833 to the present time, he proceeded to describe its principal features, aided by lantern slides projected on the screen. There were also under microscopes in the room nearly 30 slides of sections of Calamites, Calamostachys, Sphenophyllum, Lepidodendron, Bothrodendron, Lepidostrobus, Spencerites, Lepidocarpon, Lyginodendron, &c., many of these having been photographed for the series of lantern slides.—Dr. Edmund J. Spitta then described a new apparatus for obtaining monochromatic light with an ordinary mixed jet. A diagram of the apparatus was shown on the screen and also three photographs of *Amphipleura pellucida*; the first, taken with white light, gave faint indications of markings, the second, taken with a Gifford's fluid screen, showed the appearance of striæ, and the third, with blue monochromatic light, obtained by means of Dr. Spitta's new apparatus, showed the diatom clearly resolved into dots. The principal feature in the apparatus was the mounting of a Thorp diffraction film upon a corrective prism which Mr. Thorp had contrived. The diffraction film thus mounted can be used with the ordinary optical bench, giving light in a direct line from the burner to the microscope. The apparatus was exhibited in operation in an adjoining room.—Dr. P. E. Shaw sent a paper on an electrical method of taking microscope measurements.

Royal Meteorological Society, December 17.—Mr. W. H. Dines, president, in the chair.—A paper by Mr. C. V. Bellamy, on the climate of Cyprus, was read by the secretary. The mean temperature for the year at the capital city, Nicosia, is 67°·2, the extreme highest temperature being 108° and the extreme lowest 28°. The annual rainfall is about 14 inches, which falls mostly in the winter months. The author also gave particulars as to the meteorological conditions at Troodos, the sanitarium and summer resort of Cyprus, which is situated in the mountains at an altitude of more than 5000 feet above sea-level.—A paper by Mr. H. H. Clayton, of the Blue Hill Observatory, U.S., on the eclipse cyclone of 1900, was also read by the secretary. The author in a former paper discussed the meteorological observations made along the path of the total solar eclipse in the United States on May 28, 1900, and stated that he found that a cyclone followed in the wake of the eclipse—though the changes were very minute and feeble—the fall of temperature developing a cold-air cyclone in an astonishingly short time with all the peculiar circulation of wind and distribution of pressure which constitute such a cyclone. This theory was not readily accepted by meteorologists, and Prof. Bigelow, who has discussed all the observations received by the U.S. Weather Bureau, thinks that they scarcely confirm Mr. Clayton's conclusions. The author now examines Prof. Bigelow's discussion and points out that the observations really confirm his own statements.

Zoological Society, December 2.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—Dr. Hans Gadow, F.R.S., gave an account (illustrated by lantern slides) of his recent expedition to southern Mexico. He described the Valley of Mexico, and discussed the question of the axolotls and their metamorphosis. He also gave an account of his ascent of the Volcano of Orizaba, and of the two types of *tierra caliente* met with on the Atlantic and Pacific slopes, and pointed out the various phases of animal life met with in these different localities.—Dr. Einar Lönnberg contributed a series of notes, illustrated by photographs, of the variations observed in the elk in Sweden, more especially as regards the form of the antlers. These the author classed in three groups—"palmate," "intermediate" and "cervine." The last were comparable to the type lately described as *Alces bedfordiae*. These differences, in the author's opinion, were not attributable either to age or to degeneration, neither did they seem to indicate racial distinction.—A communication was read from Mr. R. Lydekker, F.R.S., calling attention to a photograph of a skull and antlers of a reindeer obtained by Mr. H. J. Pearson in Novaia Zemlia. On account of the palmation of the antlers differing markedly from that of the known races of the reindeer, Mr. Lydekker was of opinion that the specimens belonged to a new race, which he accordingly named *Rangifer tarandus pearsoni*.—Mr. H. R. Hogg read a paper on the Australian spiders of the subfamily Sparassinæ. It contained descriptions of twenty-five new species and a list of those previously known.—A communication from Mr. W. F. Lanchester contained an account of the crustaceans of the groups Anomura, Cirripedia and Isopoda (marine forms) collected during the "Skeat Expedition" to the Malay Peninsula in 1899–1900.—A communication from Mr. F. F. Laidlaw contained an account of the dragon-flies of the subfamily Cænagrioninæ collected during the "Skeat Expedition" to the Malay Peninsula.—Mr. R. I. Pocock described a new species of marine spider, discovered by Mr. Cyril Crossland in Zanzibar, under the name *Desis crosslandi*.—Mr. Pocock also read a paper containing descriptions of twenty new species of harvest-spiders of the order Opiliones from the southern continents. Two of these formed the types of the new genera Sorensenella and Lomanella.

Linnean Society, December 4.—Mr. Wm. Carruthers, F.R.S., vice-president, in the chair.—Rev. John Gerard exhibited specimens of a Polygala from Grassington, in the West Riding of Yorkshire; the plant has been named *P. amarella*, Crantz. He also showed a monstrous form of *Geum rivale*, Linn., from between Long Preston and Settle; the terminal flower was apparently normal, but about one inch and a half below the calyx there appeared a whorl of about twenty petaloid members, on extremely long "claws," and surrounded by a series of leaf-like bracts.—Mr. R. Morton Middleton showed an extremely well-developed fasciated stem of asparagus.—Dr. George Henderson called attention to a passage in the Georgics of Vergil (i. 73 *seqq.*), in which the poet, after recommending a system of fallowing, proposes as an alternative means of restoring the fertility of the soil that before taking a second grain crop the soil should be refertilised by planting it with a leguminous crop. The Romans believed that these plants actually enriched the soil, especially if the roots were plentiful. It is remarkable that recent discoveries regarding the nitrification of the soil by the roots of Leguminosæ should have been foreshadowed so long ago.—The first paper was one by Dr. Gilbert C. Bourne, on some new and rare corals from Funafuti, based on material dredged off Tutanga at a depth of 200 fathoms. The only oculinid coral was *Lophohelia tenuis*, Moseley, previously only obtained at a depth of 375 fathoms; the present specimen is figured to correct the figure given in the *Challenger* report. Seven turbinolid corals were obtained, two being new to science, and figured from photographs; one, a species of Trochocyathus, having several fossil congeners.—Mr. E. A. Newell Arber gave a digest of his paper on the morphology of the flowers and fruits of the

Xylosteum section of Lonicera.—Mr. C. B. Clarke read a paper, Note on *Carex Tolmiei*, Boott. The species was founded upon a specimen from the Columbia River, to which the author had subsequently added three other plants. The author has redescribed the original specimen, and has described two of the supposed component forms as new species.—A paper by Herr C. With, of Copenhagen, was briefly characterised by Prof. G. B. Howes, F.R.S., on the Indian Phalangidæ contained in the Indian Museum, at Calcutta. The collection was put into Herr With's hands to compare with the types of Thorell's species. With regard to the distribution of forms, the author remarks that the Indian peninsula and adjacent islands seem characterised by the presence of the subfamily Gagrellinæ.

PARIS.

Academy of Sciences, December 15.—M. Bouquet de la Grye in the chair.—On the presence of argon, oxide of carbon and hydrocarbons in the gas from the fumaroles of Mont Pelée at Martinique, by M. Henri Moissan. The gas, which was collected by M. Lacroix, emerged at a temperature of about 400° C. Besides those gases which have been already mentioned as present in other volcanic eruptions, a considerable quantity of combustible gas was found, together with about 0·7 per cent. of argon. The percentage of carbon monoxide (1·6 per cent.) would render the gas very toxic, and it is possible that many of the deaths during the eruptions may have been due to this cause.—On the stability of equilibrium and the variables without inertia, by M. P. Duhem.—Experiments on the duration of the germinating power of seeds preserved in a vacuum, by M. Émile Laurent. Samples of seeds of various species of plants were kept in the dark in a vacuum, side by side with duplicate samples in air, and these were tested after intervals of two-and-a-half years, five years and seven-and-a-half years. Fatty seeds appear to keep better in a vacuum than in air, but no general rule could be deduced from the other seeds, the results being variable.—Remarks by M. le Général Bassot on the *Annuaire* of the Bureau des Longitudes for 1902.—Perturbations independent of the eccentricity, by M. Jean Mascart.—Observations of the Giacobini comet (1902 *d*) made at the Observatory of Besançon, by M. P. Chofardet. The comet appears as a small nebula of the twelfth magnitude, and has an apparent diameter of about 45″.—On the integration of a partial differential equation of the second order of the hyperbolic type, with more than two independent variables, by M. R. d'Adhémar.—A method for the electrical separation of the metallic part of a mineral from its gangue, by M. D. Negreano.—On aluminium fluoride, by M. E. Baud. The preparation of pure aluminium fluoride, $Al_2Fl_6 \cdot 7H_2O$, is described, and its thermochemical data determined.—The action of boron chloride upon gaseous ammonia, by M. Joannis.—As previous researches on the reaction between ammonia and boron chloride have given contradictory results, the reaction has been reinvestigated, especial attention being given to the temperature of the reaction, which was kept at about −70° C. Ammonium chloride and boron amide appear to be the only products; at 440° C., the latter compound is partly decomposed, the compound $Bo_2(NH)_3$ being produced.—On a violet ammonio-manganese phosphate, by M. Ph. Barbier.—The separation of the alkalis from peroxide of manganese, by M. H. Baubigny. The alkali salts carried down by precipitated peroxide of manganese, which cannot be completely removed by washing with boiling water, can be eliminated by a preliminary washing with a concentrated solution of ammonium nitrate.—The diffusion of arsenic in nature, by M. F. Garrigou. The arsenic is obtained in the state of sulphide, which is then submitted to Bunsen's flame reaction, in which a film is produced on porcelain. It is claimed that quantities of arsenic of the order of 0·00001 milligram can be detected and approximately estimated. Remarks by M. Armand Gautier on the preceding paper. In working with such minute quantities of arsenic as those mentioned by M. Garrigou, the extreme difficulty of allowing for the arsenic derived from the glass and reagents is pointed out.—On *p*-benzene-azobenzoic acid and its derivatives, by MM. P. Freundler and de Laborderie.—On oxybenzylphosphinic acid, by M. C. Marie.—On a new method of chlorination of aromatic hydrocarbons, by MM. Seyewetz and Biot. The reagent used in the chlorination is the double compound of ammonium chloride and lead tetrachloride. By its aid, chlorine derivatives of benzene, toluene, xylene, naphthalene and anthracene were readily obtained.—A cœlomic gregarian in Coleoptera, by M. L. F. Blanchard.—On the evolution of the acrosome in the spermatid of Notanecta, by MM. J. Pantel and R. de Sinéty.—Teleomitosis in *Amoeba Gleichenii*, by M. P. A. Dangeard.—On photosynthesis outside the organism, by M. Luigi Macchiati. Some facts in confirmation of the statement by M. Jean Friedel on the production of chlorophyll assimilation outside the plant. These researches prove that the principal agent in chlorophyll assimilation in the green plant, and also in the photosynthesis outside the living organism, is an enzyme and that the chlorophyll pigment appears to act as a chemical sensitiser.—The ripening of seeds and the appearance of the germinating power, by M. P. Mazé.—On the *rôle* of vortices in wind erosion, by M. Jean Brunhes.—On the ocean current near the Landes coast, by M. L. A. Fabre.—On the origin of the transversal break of the Kosva (North Ural), by M. Louis Duparc.—The rapids in the river Kosva are due to an old synclinal more or less orthogonal to the direction of the folds.—On the deposits of phosphate of lime in the Belemnites chalk, by M. N. de Mercey.—The influence of catalytic agents upon the working of the organism: spermine, cerebrine and chloradrenal, by M. Alexandre de Poehl.—The diseases of organic demineralisation: plasmatic anæmia, by M. Albert Robin.

THURSDAY, JANUARY 1, 1903.

THE UNIVERSITY IN THE MODERN STATE.

AMONG the many documents prepared by Principal Sir Oliver Lodge in relation to the development of the University of Birmingham, there are more than one of which the interest is by no means merely local. Of these, the pamphlet entitled "Survey of the Sciences," which forms an appendix to a paper on University Development, is of especial importance at the present time, for we are glad to know that the belief that the weakness of our universities must lead to national weakness in several directions is growing with a rapidly accelerating pace.

It may be long in this slow-moving country before the influence of Brain-power on history is recognised as fully as the influence of Sea-power has been, thanks to Captain Mahan, but undoubtedly it will be bad for our future if much more time is lost.

While Sir Oliver Lodge has been investigating the "needs" of Birmingham, similar inquiries have been made elsewhere, and we have received from the Clarendon Press a statement of the "needs" of Oxford. We are glad to see that the *Times*, in a sympathetic article, goes to the root of the matter in stating that "if the pocket of the millionaire is closed, the pocket of the nation must be opened." Our eleven universities are competing with 134 State and privately endowed in the United States and twenty-two State endowed in Germany. English private endowment is much less than 10 per cent. of the American endowment, and the German State gives to one university more than the British Government allows to all the universities and university colleges in England, Ireland, Scotland and Wales put together. These are the conditions which regulate the production of brain-power in the United States, Germany and Britain respectively, so far as Universities are concerned, conditions which Sir Oliver Lodge proposes to face as manfully as he may. His paper on the "Survey of the Sciences" runs as follows:—

In a recent pamphlet I considered the question of the relation of the University of Birmingham to its central and suburban sites, with a view of determining what recommendation should be made to the Council concerning the Departments which ought to migrate and the Departments which ought to remain. I was able to arrive at some judgment on the matter except in connection with the Faculty of Science, and there the problem became so complicated that it was necessary to make a survey of the sciences in order to get the material on which to form an opinion. This survey is now printed, not only as an appendix to the former paper, but because it is hoped that it may be useful for other purposes; especially I hope that it may be of interest to those who are able to help financially in the forthcoming great educational development of the future, enabling them to realise the immensity of the area which we attempt to cover, and the largeness of the sum which could be properly invested in suitable buildings and equipment and in endowment of staff. Our position is such that if some man of power thought fit to exercise it by entrusting us with a sum of five millions for University development, it could be well and properly employed;[1] nor could such an investment fail to exercise an extraordinary influence on the progress of the country. Hitherto the ideas of this country in education and scientific research have been conceived on a wholly inadequate scale, and without proper appreciation of the vast extent of territory over which a modern University is called upon to preside.

Let us, therefore, now run over the pure sciences, and trace the collateral branches and practical applications with which they are most allied; taking them in alphabetical order, and enumerating only those sciences with which we ourselves at present in some degree attempt to deal.

ANATOMY:—is clearly so closely allied to professional medicine as practically to have drifted out of general culture; though it is to be remembered that it is in touch with Fine Art on the one side—and a course of lectures on Artistic Anatomy is annually given by our Professor or our Lecturer at the School of Art—and on another side it is in touch with the sciences of ANTHROPOLOGY and Ethnology. At the present time the course of lectures and practical instruction in the subject of Anthropology, laid down in the Calendar as an optional subject for Degrees in Science, is under the charge of the Professor of Anatomy, who has made a study of this subject and of Ethnology, particularly from the side of Prehistoric Archæology, and on two occasions has given courses of lectures on these subjects, though at the present time the plant possessed for their teaching is not large. He possesses a collection of lantern slides of an ethnological character, also a private collection of stone and metal implements, and the Summers-Freer collection is now displayed in his department; with it will shortly be exhibited—as a loan from the Geological Department to which it belongs—the Seton-Carr collection of early Egyptian stone implements; and there is, besides, a small collection of Palæolithic and Neolithic implements in the Geological Museum. A case of similar implements is in the City Museum, and there are a number of ethnological objects, some of considerable interest, in the Aston Hall Museum, which might, perhaps, become available some day for the purposes of the University.

On the practical side of colonial development modern Ethnology is a subject not altogether to be lost sight of.

ARCHÆOLOGY:—A study of the past from relics and monuments and excavated sites: skilled interpretation of which enables us to reconstruct the life of ancient times. Our present Lecturer in Greek has made a special study of Greek Archæology.

BOTANY:—Studied with us partly for its own sake as a department of Natural History, allied to Horticulture and Gardening generally, and also from the point of view of Vegetable Physiology. This science is the foundation of much of Agriculture, of Forestry, of Materia Medica, of Timber and Plant diseases, the Fermentation industries, and of many human diseases. It is allied on its morphological side with Palæontology. On its Physiological side it is largely dependent on Physics and Chemistry.

At the present time it is not now taught as a separate subject in the medical curriculum at Birmingham, but admittedly only because the course is so crowded that something had to give way.

CHEMISTRY:—This gigantic science branches out in every direction. Almost every manufacture is more or less directly concerned with it, and as a pure science it is a most important branch of Natural Philosophy in alliance with Physics.

In many places there is a Professor of its Inorganic and another of its Organic division: in Germany it is still further greatly subdivided, even from the point of view of the pure science. Flourishing departments of the new and growing science of Physical Chemistry exist at Leipzig and at other German and American Universities, in furtherance of pioneer work begun at Amsterdam and Stockholm.

As to the applications of Chemistry, they are almost too numerous to mention, and every one of them demands the full time and special knowledge of an expert. At present we have only attempted Brewing and Metallurgy.

A training in elementary chemistry, both inorganic and organic, is universally recognised as an essential ingredient in the training of a medical student.

And recently Chemistry has allied itself, on the fermentation side, with a branch of Biology, through the discoveries of the great chemist Pasteur—a subject in which our present Professor and his wife are eminent.

ECONOMIC SCIENCE:—is a branch of Sociology or the theory of Politics, of which we have recognised the commanding importance, on one of its many sides, by arranging that there shall be hereafter constituted a Faculty of Commerce. In the hands of our present Professor there is no fear lest either the term

[1] See "Concluding explanation."

Economics or the term Commerce shall be interpreted too narrowly: the two will be welded to some extent into one, and gradually it is to be hoped that the treatment of these subjects of national moment can be established on a sound and broad educational basis.

EDUCATION or Pædagogy.—The science of Education is coming to the front of practical politics in a most impressive manner just now. All that we attempt in this direction at present is the Training of a limited number of Primary Teachers, both men and women: a department which constitutes a successful and promising beginning of a most important work. But some part of the barrier between primary and secondary education is shortly to be broken down, and the Government is wisely going to insist on a training for Secondary Teachers also. It is important to remember that, for this work, teaching must be provided in all departments of ordinary knowledge, and by no means in the Arts subjects alone; though those no doubt constitute the backbone of the course. Also that methods of teaching the substance of Science (including Mathematics) and Modern Languages, in schools, are less developed and systematised than are the disciplinary methods for drilling in Ancient Languages, Euclid and Algebra. A Professorship is necessary if we are to enter into effective relations with and duly to influence secondary schools.

ENGINEERING. This science is, even more than chemistry, overweighted with its own applications; so that there is a tendency to regard it solely as an applied science. But it has a large and most important pure-science aspect, too; and on this side may be considered to consist of Applied Mechanics and Physics: meaning by that, such subjects as Thermodynamics, Elasticity, Strength of Materials, Theory of Mechanism, and much else; not to mention the enormous subject of Electrotechnics—the foundation of Electrical and Telegraphic Engineering; in fact, the ground to be covered is so large that but few Physicists are competent to treat the whole science adequately from an engineering point of view, and so a good deal falls to the province of the Professor of Engineering. At the same time a thorough knowledge of the groundwork of the pure Science of Physics and Mechanics is essential to the training of every engineer who aspires to rise to the higher ranks of his profession.

We have only to run over the aspects of Civil Engineering in its limited customary sense--Bridges and Tunnels, Reservoirs, Canals and Railways; and then to remember Marine Engineering and Military Engineering—to recognise that the whole subject is obviously gigantic. It alone could cover the whole site and employ a dozen professors.

GEOLOGY.—The great science of the earth's crust claims to deal with the constitution and history of the earth as a whole. It is in touch on the one hand with Astronomy—a science which at present we do not here attempt—with GEOGRAPHY, a science which has many aspects, both on the side of nature and on the side of the distribution of man, which are dealt with to a considerable extent by our present Professor of Geology—with MINERALOGY, which he also treats—with PALÆONTOLOGY, the Botany and Zoology of the ancient world, in parts of which he is a world-known authority--with Physics and with Chemistry, more especially perhaps with Physics, for many of the problems are the physics of the earth's crust. All this on the pure science side.

On the side of Applied Science it is in obviously close connection with Mining, with Civil Engineering, with Water Supply and with Agriculture.

HISTORY:—the science of humanity in the past, is closely allied with Sociology and Economics; it is often treated in a more literary manner than most sciences, and hence is sometimes taken for a time by a Professor of Literature; but never satisfactorily so. The whole range of ancient and modern history, of events and institutions and of constitutions, is large enough to demand the attention of several specialists, if the ground is to be adequately covered.

On its practical side it has close relation with Law and with Commerce.

MATHEMATICS:—the science of number and form, in its elementary stage, is an essential ingredient in all education, and hence is partly associated with the Faculty of Arts. In its higher stages it is essential to the Engineer, and is becoming necessary to the Chemist; and for these purposes a more immediately practical course, proceeding more quickly over the rudimentary portions, is desired. In still higher stages it is essential to the Physicist, the Astronomer, and the Natural Philosopher generally. And in its highest stages it constitutes a pure science of unexampled beauty and perfection.

The so-called Applied Mathematics, or Theoretical Mechanics, is closely allied with, and, indeed, trenches upon the mathematical side of Physics; and there is ample room for two or more professors of the different branches of Mathematics. Some day this statement will become practical politics.

MEDICINE:—is the only science which at present is adequately treated in England. A five years' course is devoted to its acquisition: and it is subdivided into a proper number of constituent parts, each dealt with by a special Lecturer.

Besides the three great sciences Anatomy, Physiology, Pathology, with which last at present the developing new science of Bacteriology is associated, there are the great practical Arts of Medicine and Surgery, together with the several branches called respectively Hygiene, Therapeutics, Materia Medica, Midwifery, Gynæcology, Forensic Medicine, Toxicology, Mental Diseases (the Pathological side of Psychology), Ophthalmology, each with a special Professor. Besides these we might have a Lecturer on Diseases of Children, another on the Ear and Throat; and we have seven Lecturers in Dentistry, a branch in which we give special degrees. There is also Pharmacy, including the training of Pharmaceutical Druggists, a branch of work we have not yet undertaken, but for which there is some demand.

Medicine therefore is a model according to which all the great sciences should be subdivided and conquered; and to some extent it is coming to be so in Germany. This country is ignorant of Science: and the administrative and commercial classes are not yet awake to its value.

PATHOLOGY.—This vitally important science used to consist wholly, and still consists largely, of post mortem operations and the study of fresh morbid specimens, with the object of throwing light upon the processes of disease; so that an essential appendage to the subject is its museum of morbid preparations; which indeed subserves also many practical branches of Medicine and Surgery.

A good *Pathological Museum* is one of the most valuable assets of a Medical School, and has been found to be a powerful factor in attracting students, as well as in maintaining the interest of medical practitioners, to whom it may be a considerable aid in difficult cases.

Nowadays the science has been illuminated and almost revolutionised by the discoveries of BACTERIOLOGY; and it bids fair to achieve for humanity the greatest service which on the terrestrial plane can be accomplished, viz., the earlier and surer recognition, the intelligent treatment, and ultimate removal, of many forms of disease.

The science is allied to Physiology, to Chemistry, to Zoology, and to Botany, and it is the root principle of Medicine and Surgery.

Its researches seem likely to open up the tropics to white habitation, thereby greatly enlarging the effective extent of the earth's surface; and, if it progresses as it has recently been doing, it is to be expected that the average duration of human life everywhere may be largely and efficiently prolonged.

PHYSIOLOGY.—This splendid science deals largely with the functions of the human body in health—indeed with organic or vital functions generally, save that those of the lower animals and of plants are generally relegated to the special sciences of Zoology and Botany. It is the Physics and Engineering and Chemistry of live machines. It is closely connected with Anatomy, which concerns itself with the discovery and enumeration of the structures themselves; and on the practical side it manifestly is closely related to Medicine. For a due understanding of the functions of the heart, the liver, the muscles, the lungs, the viscera, the nerves, the brain, the kidney, the stomach, the glands, the eye, the ear, and the other organs of the body, is essential to their proper treatment, whether by hygienic precautions or by remedial drugs; just as an exact anatomical knowledge of their position is the foundation of surgery.

The microscopic branch of Anatomy, called HISTOLOGY, the science of the minute structure of the tissues, is generally at present dealt with by the Physiologist, doubtless because these parts are intimately concerned with the business of secretion and with vital functions generally.

It has recently been customary to equip the Physiologist with a quantity of elaborate Physical instruments, chiefly for a special

study of the phenomena of nerves—in which of late years many discoveries have been made. The electrical concomitants of nervous action have been found very helpful in elucidating the processes and determining their true relations, even if they do not turn out to be themselves an essential part of the process; and accordingly the science demands extensive and expensive equipment.

From the side of the brain and nervous system it is related to the analysis of mental functions in Psychology.

PHYSICS.—Of the science of Physics I dare hardly trust myself to speak: suffice it to say that it is the chief part of Natural Philosophy, the science which covers everything except the treatment of life and mind, and it underlies every other science. It seeks to explain the phenomena of Chemistry and of Physiology, so far as can be done without trenching on the domain of Biology. It is closely allied to ASTRONOMY, it measures sizes and distances, and the chemical constituents of the heavenly bodies. It is concerned with all exact measurements, with weighings and gaugings and surveyings, all geodetic operations, and a great part of Navigation. It includes Meteorology, which is the physics of the atmosphere; it deals with Heat and Light, and Sound, including the theory of Music, with Magnetism and Electricity, with waves and vortices, with the flow of fluids, with the elasticity of solids, with the theory of gases; and it is the foundation of Engineering.

On its practical side it has blossomed in every direction: witness the pump, the barometer, the telescope, the microscope, the photographic camera, the steam engine, the telegraph, the electric motor, the electric light, the X-rays; less obviously in a multitude of other directions.

On its theoretical side it is the most advanced and extensive of the whole of the family of sciences; and a much larger staff is necessary if we are to occupy its territory in even a moderately respectable manner.

In the department of exact measurement and mathematical electrical theory our present Professor of Physics has made for himself a world-wide reputation; and the limits of discovery in a science like this are controlled more by the lack of time and of material equipment than by almost anything else.

PHILOLOGY:—the scientific treatment of language: a comprehensive subject which ranges from a competent understanding of the derivation of words to an interpretation of Hieroglyphics and of Cuneiform inscriptions, to Palæography—or the study of Ancient Manuscripts. It is thus allied on one side to History, Sociology and Folklore, on another side to Ethnology and Archæology. It welds languages into families, and traces their relationships, and on its practical side is a necessary element in the thorough study of any modern language. It is a subject in various departments of which our Professor of Classics and Lecturer in Latin are experts.

PSYCHOLOGY:—may be regarded as the highest of all the biological sciences, being the theory of mind and of mental operations in general; in another aspect it constitutes the fundamental substratum of knowledge, being the study of the processes by which we recognise the external world, and all the facts dealt with by other sciences: it is a study which on its practical side is closely allied with Education, which so far as it is scientifically based must rest upon it. In recent times experimental methods have been applied to the simpler mental operations, thus giving to the subject increasing definiteness and precision; and a large extension of knowledge is being foreshadowed in this direction by the labours of a few, as yet hardly recognised, pioneers.

Moral and Political Philosophy.—On the theoretic side Psychology lies at the base of any sound treatment of the phenomena of will and conduct, the relation of the individual to his social and political environment, the meaning and bearing upon human life of legal and State organisation. The treatment of these subjects has attracted the best minds at the highest stages of social development, both in ancient and modern times, from Plato and Aristotle to John Stuart Mill and Henry Sidgwick.

Logic and Metaphysics.—On still another side Psychology is an introduction to Logic, the science which seeks to analyse the processes followed by the reason alike in ordinary affairs and in the more familiar kinds of scientific investigation, and while offering a practical discipline in logical method and the conduct of the understanding leads in turn to METAPHYSICS or General Philosophy; which may be defined as the examination of the relation of the forms under which we know the world around us—matter, motion, life, intelligence, art, science, religion—to one another, to reality in general, and (under the name THEOLOGY) to the Divine Mind.

ZOOLOGY:—The study of animal life, from the lowest amœba to the highest mammal. On the practical side Zoologists are sent out by the Colonial Office to Ceylon to renovate the Oyster and Pearl Fishery there; by County Councils to study and improve the conditions of the sea-fishing industry round our coasts. The science has an important bearing on many of the operations of farmers, beekeepers, pigeon fanciers and veterinary surgeons; and in the United States a knowledge of many zoological facts, relating to sheep and cattle, as well as to blight, the Colorado beetle, potato-bug, and such like pests, is disseminated among farmers by a series of pamphlets issued by the United States Department of Agriculture. Zoologists are beginning to take their part also with the botanists and pathologists in the extermination of malarial and tropical disease, in which a knowledge of the life-history of the mosquito and such like insects is so important; and already it is coming to be more than suspected, especially in the light of South African enteric experience, that flies and other household insects are specifically dangerous, too.

A knowledge of Elementary Zoology, or at least of Comparative Anatomy and Physiology, is insisted on in every medical school.

The science of Zoology is sometimes sneered at as having to do with grubs, and butterflies, and snails; and so it has; but, though it has made no adequate beginning as yet, the greatest of problems lies before it—or before it and Physiology together—in the future, viz. the elaboration of a theory of the nature of life and death.

CONCLUDING EXPLANATION.

In venturing to name earlier in this pamphlet (see p. 193) such a sum as five millions, I have had in view certain considerations which it may be well to set forth.

First it has been found that the Carnegie donation to Scottish Universities is insufficient to attain its objects, and already it appears likely that it may have to be doubled.

Next it is well known, and indeed painfully familiar to all who have to do with administration, that every new department started, and every new building erected, means an increase of current expenditure and a drain upon resources. Expenditure is called for on behalf of rates, portering and cleaning, heating and lighting, maintenance, depreciation and supersession of equipment, and materials for experiments and processes. There are also annual grants to be made to the Library, to the various Laboratories and Museums, and to departmental Libraries. Then there is a large disbursement for salaries of demonstrators and curators and assistants and technical instructors. All these expenses come out of revenue, and are probably best provided for by the income derived from fees, and from the contemporary support of County and other bodies so as to preserve dependence on the interest of the living generation. But it is highly desirable to keep fees low—not by any means to abolish them, but to keep them low—so as to bring higher education within reach of all who are able to make use of it: a number which, with the improvement of schools, will probably be rapidly increasing. Hence it is probable that the above-mentioned items of annual expenditure will absorb the whole of the ordinary annual income and leave nothing for the payment of the chief Professors and Lecturers. Everywhere it has been found essential that chairs shall be endowed, so as to put them on a permanent and substantial basis; moreover, it is vitally important to be able to attract the best men, wherever they are to be found. At the present time it is not usually possible to compete with other places for the best men unless we can offer a sum comparable to 1000*l.* a year, and in some subjects more.

An invested million will therefore on the average relieve the annual income of the stipends for 30 principal chairs. There must be a large number of Lectureships, or subsidiary and supplemental chairs, and 60 of these at 500*l.* each could be provided with the second million.

The buildings already in progress on the new site are to cost more than a quarter of a million, and the remainder of what has been sketched out and actually contemplated will cost the other three-quarters. Another half million at least will be needed to equip them properly.

The older or central site will also need considerable enlargement, and fresh buildings should rise there. Half a million may be set aside for ultimate building and equipment on and near the Mason College site.

Four out of the five millions are thus accounted for; the fifth is intended for a real attempt at scientific research in all departments. A fund by which men could be sent to any part of the world: to study tropical diseases, or fisheries, or mining possibilities—to investigate either nascent industries or injured industries of any kind: a fund which could equip research laboratories at home, and could defray the expense of researches undertaken on a large or engineering scale, so as to bring in rapidly some practical results. At present there are men who perceive how many things could be reformed or improved, whether in purification of the atmosphere, or in novel modes of locomotion, or in many other ways; but they lack the means to demonstrate their plans or to try experiments. Manufacturers and Municipalities sometimes try experiment on a very extensive scale indeed—a really commercial scale—and in case of failure the resulting experience is over-dear. The endowment would not allow experiments on such a scale as that; considering the variety of subject, the amount available for each would permit of no extravagance. Some of the experiments undertaken would undoubtedly fail, yet the success of a few would far more than compensate for the failure of many, and the activity could not but conduce to progress.

The fund would have to provide, not only the necessary appliances and assistance, but it would endow fellowships for post graduate study, and would attract workers from many parts of the world, and certainly from the Colonies.

One Principal could not possibly supervise all the multifarious activities which we have thus supposed may some day be called into being. There would have to be a Research Principal (whatever he might be called), to organise and superintend the scientific and post graduate study; a Technical Director, in touch with all the technical departments; and an Educational or General Head, to supervise the general scheme of the College in all its various avenues to a degree, and to take a lead in whatever conduced to general culture.

If the scheme is lavish it represents lavishness in the right place. It is the kind of lavishness for which the nation is waiting—one of the few kinds of which hitherto it has been afraid.

> "There is that scattereth but yet increaseth:
> There is that withholdeth more than is meet, but
> it tendeth to poverty."

These lines refer not to individual wealth alone, but to National wealth also. We have failed to make the most hitherto of the brains and energy of our more able and specially-gifted youth, but have cramped them by the necessity of earning a living: a process wholesome enough for the individual, and right for 999 out of every thousand, but for the remaining one far less repaying to the Commonwealth than the special service which he could render, if set free and encouraged by suitable surroundings for a few years of research, following on a thorough educational preparation. Not all of these would justify their selection: nine-tenths of them even might do only moderately well; but the discoveries of the select tenth would be of incalculable value. The world has been wasteful of its genius hitherto. It thinks too facilely that people exceptionally endowed will struggle to the front somehow. A few do, but a number do not; the conditions are not favourable; and the struggle for existence, though doubtless a stimulating training for the hardier and sturdy virtues, is not the right atmosphere for the delicate plant called genius. Different kinds of treatment are suited to different characters, and the hot-house plant will not thrive in bracing arctic air.

From the Trust Deed with which Mr. Carnegie has endowed a research Institution at Washington with ten million dollars, I extract the following altogether admirable statement of "*aims*":—

"1.—To promote original research; paying great attention thereto, as one of the most important of all departments.

"2.—To discover the exceptional man in every department of study, whenever and wherever found, inside or outside of schools; and to enable him to make the work for which he seems specially designed his life work.

"6.—To ensure the prompt publication and distribution of the results of scientific investigation; a field considered highly important.

. . . "The chief purpose of the founder being to secure if possible for the United States of America leadership in the domain of discovery, and the utilisation of new forces for the benefit of man."

MUTUAL AID.

Mutual Aid, a Factor of Evolution. By P. Kropotkin. Pp. xix + 348. (London: Heinemann, 1902.)

THIS book is undeniably readable throughout. The author has a creed which he preaches with all the fervour of genuine conviction. He is anxious to make converts, but his zeal never leads him to forget fairness and courtesy. Those who disagree with him may learn much by studying the book.

The line of argument is, briefly, as follows. In the case of animals, there is very little evidence of any struggle for existence among members of the same species, though plants, beyond all doubt, jostle their own kin out of existence. Animals are, as a rule, banded together for mutual protection, and those that have the best organisation for mutual defence are those that thrive best. Such species are represented by large, often by countless, flocks. Those that are least sociable, such as the great carnivores, are far less vigorous, to judge by their small numbers, and barely hold their own. The term "struggle for existence" should not, therefore, be used in a literal sense, as if there were an unceasing internecine war between the members of the same species, a limited amount of food available and no individual able to dispel the cravings of hunger except by robbing his own kin and reducing them to starvation. So far from this, we see mutual aid almost everywhere. There is a struggle for existence, but only in a wide, a metaphorical, sense. There is at normal times plenty of food, and there is, therefore, no need for fighting among the members of a species. Rats are a painful exception, and the cries of distress that come from cellars tell of their fights and their cruelty.

Turning to men, we find that mutual aid is, or at any rate has been in the past, even more general than among animals. Among savages, mutual aid is the chief factor in evolution. The individual is never isolated, but is one of a clan. Among barbarians, we find the same tendency to sociability and cooperation, but historians, by dwelling exclusively on wars, have misrepresented the facts. When the clan broke up, men formed village communities. So unwilling were they to fight that they got soldiers to protect them, and in many cases became the slaves of their protectors. The risk of this led to the growth of the mediæval town; it was a union of several village communities for defence against marauders. Within the larger community of the town were smaller associations, the guilds. In these mediæval towns, the arts flourished to an extraordinary degree. Sometimes leagues of free cities were formed, and held their own against all enemies. But in time these little homes of freedom disappeared. The big centralised State arose and crushed out those smaller communities that existed for mutual help. Within the State has sprung up an individualistic civilisation, but even now there is an enormous amount of mutual help. There are benefit societies, cooperative associations, trades' unions.

Moreover, the poor have the habit of constantly helping one another in all their troubles.

In every line of the book you see the eagerness of the writer to make the lives of men happier. So zealous is he that he attributes to the lower animals a benevolence similar to his own. But has he correctly represented the struggle for existence? It is true that he partly succeeds in making good his first contention, that there is not much evidence of a fratricidal struggle between members of the same species. Still, there is a great deal more than he would have us imagine. Rats, he owns, are sad offenders. Can we be sure that the same spirit does not show itself among other animals when a crisis comes? And crises, though Prince Kropotkin does not allow it, are all-important from the point of view of natural selection. Do not cattle in time of drought trample each other to death in their efforts to get what water remains in a pool here and there? Do they not, even in normal times, prod with their horns and bully a weakly member of the herd? Mr. W. H. Hudson, a most unwilling witness, testifies to this. Even maternal affection is strictly subordinated to the needs of the species. I have recently heard of a well-authenticated instance of a kid which was being gored to death by its mother because it was weakly, and it was only saved by being removed from her. Pigeons are very affectionate towards their young, but as soon as the young are able to fend for themselves, the affection comes suddenly to an end, and is often succeeded by a strong tendency to tease and worry.

Prince Kropotkin tells of crabs that worked hard and long to put one of their kind, that had got overturned, right side uppermost. This is indeed a remarkable phenomenon, hard to parallel even among animals a great deal higher than crabs. Swans will drive their young away from their pond. Eagles will not tolerate rivals within a certain radius of their nest. Besides this, there is sexual selection, which often takes the form of selection by battle. I have read Prince Kropotkin's book from cover to cover, and find no mention of the habit, so common among males, of fighting for supremacy. In the index there is no reference to it. Yet sexual selection is an important form of natural selection: its total omission is extraordinary.

Prince Kropotkin certainly succeeds in showing that mutual aid is very frequent among members of the same species. Probably Darwin underrated the amount. But it is because they have formidable enemies that they assist one another. In fact, the struggle for existence is all the keener because they are formed into troops or armies. Mutual aid cannot "eliminate competition" (p. 74). True, it dignifies and ennobles it, but it makes it more intense. Whatever vigour any species possesses results from competition. If civilised men are stronger than barbarians, it is not because they suffer less from competition. The civilised races have gained their strength in the stress of the struggle for existence, and they retain much of it because there is still a struggle against cold, want and disease. The struggle against physical conditions is the only one that Prince Kropotkin recognises as normal and natural. As for lions and tigers, he deprecates their existence; in his eyes, they have no *raison d'être*. Yet they may claim the credit of having developed the habit of mutual aid among the ruminants. What need for mutual defence if there are no enemies? Birds of prey in the same way have fostered cooperation among the members of the species on which they make their raids.

As to the comparatively small numbers of the carnivorous animals, we need not attribute this, as our author does, to their want of cooperation. It is a question of food supply. Plants are more abundant than animals because they live on inorganic food, and that is plentiful. All animals require protoplasm that has been prepared for them by vegetables. This introduces a limitation of the food supply. The flesh-eaters must have it still further prepared by the vegetable feeders. Were there yet another class of animals that could subsist only on the flesh of carnivores, they would be still fewer in number than the class on which they preyed. Prince Kropotkin seems unaware of the influence of one species upon another. The keen eye of the falcon and his splendid swoop have necessitated counter developments in the species among which he seeks for his victims. Mere physical conditions, seldom changing, would never have brought about the evolution of the noblest forms of life. This could only be achieved through the interaction of competing species. The advance of one—the gain of keener sight, of greater speed or greater courage—has necessitated a corresponding advance in others.

Prince Kropotkin's failure to grasp this prevents him from understanding the growth of civilisation. His creed does not allow him to understand that the clan, the village community, the mediæval city, all derived their vitality from the fact that they had enemies to contend against. War necessitates loyalty and cooperation, as our author, at least in one passage, owns, and yet he will not allow that it has played any good part in evolution. The passive friendliness of all law-abiding citizens towards one another and the efficiency of the police prevent cooperation from being what it once was. It is only the largest cooperative association, the State, that can evoke enthusiastic loyalty and devotion, and this is, obviously, because nations have not yet done with war. If the law did not prevent active hostilities between trading associations, we should soon see institutions similar to the mediæval cities arising. Moreover, our philanthropic principles hinder us from bringing that pressure to bear upon the idle and corrupt which was essential to the successful working of the old guilds. Prince Kropotkin tells us that "the craft organisation required, of course, a close supervision of the craftsmen by the guild." An idle member might be ejected, and his fate would, probably, be far worse than that of the modern idler who tramps from workhouse to workhouse. It is not in benevolence we fail so much as in the sternness that is wanted for the proper treatment of the dregs of society. There are many persons whom society can only help by compelling them to help themselves. And such drastic measures Prince Kropotkin does not seem to recommend. He would abolish individualism. But how would he make the loafers, who will not work for themselves, bestir themselves on behalf of an association?

F. W. H.

THE FORESTS OF UPPER INDIA.

The Forests of Upper India and their Inhabitants. By Thomas W. Webber. Pp. xvi + 344; with 2 maps. (London: Edward Arnold, 1902.) Price 12*s.* 6*d.* net.

THE title of this interesting book is somewhat misleading. In the first place, the author deals with only a fraction of the forests of Upper India, namely those of the districts of Kumaon (with a visit to Thibet), Gorakhpur (with a dash into Nepal), Jansi, Bundelkund, and the northern part of the Central Provinces. In the second place, he gives far more information regarding the inhabitants, whether men or animals, than of the forests themselves. Indeed, the information regarding the latter is very sketchy and not up-to-date. What the author does say in this respect refers to a state of things existing some thirty-five to forty years ago, and we have now far more complete accounts than those contained in this volume. Nor is the information in this respect always very accurate. On p. 38, for instance, he gives the area of the Kumaon hill forests as 15,000 square miles, while the whole district in which they are situated is given as 150 miles long and 100 broad, which also comes to 15,000 square miles. At p. 184, on the other hand, the area of forests surveyed in Kumaon is said to amount to 1074 square miles. Again, at p. 41, it is stated that the silver fir grows on the northern slopes at an elevation of 12,000 feet, whereas that is practically the upper limit, the tree being usually found between 8000 and 12,000 feet. On p. 194, the author says that Sal is found in the Mysore hills and Tenasserim. This may have been believed fifty years ago, but it has long since been found that the southern tree is not Sal, but another Dipterocarp. Of Deodar, the most important tree of the Himalayas, we hear very little.

The information given of the forests serves, as a matter of fact, only as a frame, into which the author places the description of his travels, *shikar*, or sport, and enumeration of animals which he has met. This account will, we feel sure, interest many readers. The author despises ordinary shooting as now practised in these islands, but he loved stalking interesting animals, especially big game, in many of the out-of-the-way places which he visited between the years 1861 and 1871. He also gives an animated account of various wild or uncivilised tribes and their manners and customs. One of the most interesting parts of the book is, no doubt, that in which he tells us that, just inside Thibet, he came across the descendants of the famous Huns, which overran the greater part of Europe some 1500 years ago. Whether his surmise is correct or not, we shall not risk to say, but from the description which he gives of the present-day Huns, it is clear that these must have greatly degenerated since the sojourn of their ancestors in Europe.

The author's account of the animal life in the districts which he visited is very full and is told in an attractive manner. At the same time, we think that literary license and colouring have been employed in a somewhat excessive manner. It is quite wonderful to read of all the different kinds and numbers of quadrupeds and birds which our author has seen and, in many instances, shot. We cannot do better than give an extract from the chapter headed "The Bori Forest" (pp. 299-303):—

"The glory of the village was an immense banian-tree, standing alone and covering half an acre of level ground. . . . This great fig tree is in itself a whole aviary, affording both shade and figs, and insects and grubs, and safety from numerous enemies of the hawk tribe. There is the golden oriole (*Oriolus kundoo*), which makes a melodious whistle very like the ring of glass, short, single, and descending two octaves . . . Many little squirrels . . . came skipping and cocking high bottle-brush ringtails. . . . Among the thick, shiny leaves there is a sparkle of canary-yellow and bright scarlet; this is the female and male minivet or cardinal bird. There are many kinds of woodpeckers, which tap on the stems and screech. A dark-greenish bird sits in the shade—the koel. He makes the grove resound with his frantic cry, 'I've lost my shirt.' . . . The air is full of swifts and swallows, darting ever after insects. . . . At no time or place is there an interval in the wheeling of long-winged kites high overhead. . . . Towards evening . . . a little owl says 'Piu!' from the recesses of the many air-roots which hang overhead. Then . . . a hundred green paraquets screech all together. . . . There are flocks of the common large green paraquet, the smaller rose-collared *tota*, and many kinds of plum-headed paraquets, and slaty-headed and red-breasted parrots of all sizes. . . . There are notes of various owls . . . the purring also of the goatsucker. . . . Stag-beetles drone as they swing by, and cockchafers and the cicadas in the trees keep up a creaking which seems always in the air, and there is never silence."

Who would not like to see such a banian-tree and to sit under it and watch the variety of life here depicted by the author?

Men with a more practical turn of mind would perhaps fasten on another very short passage in this chapter (pp. 309-310), where it is said:—

"The complete exclusion of jungle fires, which had been successfully carried out for some years previously, certainly showed its effect, as fine saplings, grown from seed, of teak and other sorts were plentiful through the forest."

The author dismisses the subject with these few words, and yet this operation was of immense importance, as the protection from fire of the Bori Forest in the Central Provinces was the first thoroughly successful experiment of the kind, continued over some forty years. It was the beginning of a system of successful fire protection now carried on in all Indian provinces, a system which gives protection to some 30,000 square miles of the more valuable Indian forests. One of the greatest achievements of the Indian Forest Department is the success with which such extensive areas of valuable forests are now protected from the devastation formerly wrought in them by the annual forest fires. Whoever may have started the idea, so much is certain, that the officer who was the first to be thoroughly successful in this great work is Colonel Pearson, at that time Conservator of Forests in the Central Provinces.

In the appendix, the author gives us his ideas of "the scientific management of forests," and he winds up by reading a lecture to the Government on the neglect which forestry has met with in these islands. The author draws attention to the serious consequences which are likely to arise if something substantial is not done at once in augmenting the wooded area of Great Britain and

Ireland, as well as in introducing some rational system of management into the forests of the colonies. Let us hope that his words will fall on fruitful ground.

In conclusion, we cannot omit expressing our admiration for the cheerful way in which the author went through most fatiguing journeys and the healthy tone of his remarks on the love of nature. We feel sure that the attractive way in which the book is written will secure for it many readers.

THE ASCENT OF MIND.

Mind in Evolution. By L. T. Hobhouse. Pp. xiv + 415. (London: Macmillan and Co., Ltd., 1901.) Price 10*s.* net.

IN this able and thoughtful work, Mr. L. T. Hobhouse distinguishes five stages of correlation in the ascent of mind, from the first glimmerings of consciousness in some lowly organism of primeval times to the systematic thought of the man of science or the philosopher and the intuitive insight of the poet or artist. The first of these, placed in a category by itself, is the pre-intelligent stage, wherein there is an indirect correlation of experience, reaction and welfare before intelligence (which is defined as the capacity of the individual to learn from experience) comes into play. The behaviour of the organism is, at this stage, the outcome of inherited structure, and if any variation of structure secures a more suitable response, that is, one better adapted to preserve the organism or its offspring, such a structure would tend to be "selected," since the individual in which it occurred would have an advantage in the struggle for existence. In this way, inborn tendencies to a given method of response may be correlated with the past experiences of the race.

It will be noticed that the word "experience" is here used in a non-psychological sense. Instinctive reactions are the culminating products of this stage of pre-intelligent development. Above and beyond this comes the comprehensive category, the second of the two which Mr. Hobhouse distinguishes, wherein the correlation is based on individual (psychological) experience. This category comprises four stages; first, that of the unconscious readjustment, where the pleasure or pain consequent upon instinctive or random response to stimuli modifies subsequent reactions in a manner determined by the nature of the feeling; secondly, that of concrete experience and the practical judgment. Here behaviour becomes purposive, and the appearance at this stage of actions definitely directed to, and determined by, the ends which they serve, is regarded by Mr. Hobhouse as perhaps the most critical moment in the evolution of mind. In purposive action, so far as it is purposive, there is no fixed habit, but the response to the surroundings is determined by the effect which it will have in the particular case; that is to say, by the relation between act and consequence. Hence the organism at this stage does not respond uniformly to similar surroundings, but takes into account anything that, though outside the range of immediate perception, is relevant to the object to be attained. Within this stage are reached the limits of animal intelligence.

The connection between the perceived relation and the action based on it remains, however, unanalysed. The steps by which this bond of connection is analysed out as a distinct content of thought lead us to the third stage, that of conceptual thinking and will, and of the correlation it involves, language, both as cause and effect, is the central feature. In scope, the correlation that is now made possible is immeasurably widened. In the conceptions of this stage, thought first finds itself possessed of contents set free from the line of practical interests and also from strict conformity to the perceptual order. In this way a "world of ideas" is formed, going beyond as well as behind experience, and the conceptions which people this world form ideal schemes to which grouped experiences may be referred. Conduct is adjusted to meet the requirements of self or others as persons, of society as an abiding structure, or of morality as a system of universal rules. In fine, the correlation is now between the focussed results of connected bodies of experience and broad purposes of life or general standards of conduct.

The fourth and last stage—that of rational system—arises when the formation of a coherent, self-supporting, exact and exhaustive body of knowledge begins to be an explicit object of mental effort. The stage would be complete when such a system should embrace the conditions and possibilities of evolution, and should reach a complete synthesis of reality as a whole.

Such, stated for the most part in his own words, is a summary of the successive steps which Mr. Hobhouse traces in the ascent of mind. His work is characterised by breadth of view, logical development and fertility of illustration. It is an earnest attempt to grapple honestly and fairly with difficult problems in a spirit of serious investigation. Personally, I am of opinion that Mr. Hobhouse's psychological stages one and two—those of unconscious readjustment and of concrete experience—are much more closely related than is concrete experience to conceptual thinking, which again shades off into that of rational system. Dr. Stout's broader division into perceptual and ideational phases of mental development seems preferable. Within these might fall Mr. Hobhouse's subdivisions. The generic differences between the broader categories are not difficult to trace; but the specific differentiation of the subgroups is a less easy matter and one which leaves room for more difference of opinion.

A noteworthy feature of Mr. Hobhouse's work is the careful record of observations conducted under experimental conditions on cats, dogs, a rhesus, a chimpanzee, a seal and an elephant. His method seems preferable to that of Dr. Thorndike, since the conditions are less cramping to the intelligence; and though his interpretation is in some cases open to criticism, his honesty of purpose is unquestionable. If, making due allowance for differences in the usage of technical terms, for diversities of outlook, in a word, for the personal equation, we compare his results—for example in the study of monkeys—with those of Dr. Thorndike and of Mr. Kinnaman, we cannot but be struck by the large measure of agreement that may be found in views which, to some readers of their works (and perhaps still more to the writers themselves), may seem divergent. C. LLOYD MORGAN.

SCOTTISH GEOLOGY.

The Geology of Eastern Fife. By Sir Archibald Geikie, D.C.L., F.R.S. Memoirs of the Geological Survey, Scotland. Pp. xv + 421; with map, 12 plates and 71 figures in the text. (Glasgow, 1902.) Price 8*s*.

IT is not given to every author of a Geological Survey memoir to write an interesting as well as instructive volume. Too little attention has been paid to style and composition, while the necessity for recording many and often dry facts has had a tendency to obscure the philosophy of the subject in many of the official publications.

When, however, as in the present instance, the information is conveyed in a pleasant style and in well-chosen language, we feel that the science is placed on a higher level and that the task has been performed in no perfunctory spirit, but with the desire to make art a companion of science.

Sir Archibald Geikie has occupied much of his leisure time since he retired from the Geological Survey in writing a memoir on the geology of eastern Fife, which may be regarded as a sequel to his "Geology of Central and Western Fife and Kinross," published two years ago. He conducts us now eastwards into a region perhaps fuller of geologic interest. Composed mainly of Old Red Sandstone and Carboniferous rocks, it is diversified by the occurrence of contemporaneous eruptive rocks in both systems and by the further evidence of later igneous action, probably for the most part of Permian age, in numerous volcanic vents—necks or chimneys—filled with tuff or agglomerate, and in sills and dykes of dolerite and basalt. As the author points out, there is hardly any other region in Britain where lessons in practical geology could be better taught. On the coast, the rocks have been dissected and washed clean and bare by the tides, and they afford illustrations of stratification, jointing, curvature, intrusion and other characteristic structures of the earth's crust. Fossils in great variety are found in many of the strata. The Old Red Sandstone of Dura Den is a classic locality, one of the chief repositories of the fishes such as Bothriolepis, Phyllolepis and Holoptychius. In the Carboniferous rocks, there are banks of corals and crinoids in the marine limestones, shales with ostracods and bone-beds with fish-remains in the estuarine strata, and plant remains with erect and prostrate tree-trunks in the more distinctly terrestrial deposits. A general list of all the fossils has been drawn up by Mr. B. N. Peach, who acknowledges the help received from several specialists.

Workable coal has locally been found in the Calciferous Sandstone Series, but the chief development of this mineral is in the Carboniferous Limestone Series and in the Coal-measures. Full particulars of these strata are given.

The author's attention is naturally attracted to the eruptive rocks, and more especially to those which have invaded the Carboniferous strata. The sills form a remarkable group ranging from a few inches to masses more than 100 feet thick that form prominent ranges of hills. They are nearly all dolerites. The distinctive feature in the geology of eastern Fife is, however, the series of volcanic necks, of which about eighty have been observed; and, as the author remarks,

"they furnish an unrivalled body of material for the study of phenomena in the structure of volcanoes which are inaccessible at the active vents of to-day."

They

"mark the sites of former volcanic orifices by which egress was obtained to the surface for highly heated vapours, gases and other materials from the interior of the earth."

Notes on the petrography of the igneous rocks are contributed by Dr. J. S. Flett and Mr. H. J. Seymour.

Many other topics of interest are dealt with by the author, such as the glaciation, as evidenced by the ice-worn rock surfaces, the Boulder-clay and the Kames. The raised beaches and submerged forests likewise claim attention, and there is an instructive chapter on the latest geological changes in which the famous Links of St. Andrews and other places are duly described.

The work is illustrated by a clearly printed geological index map and numerous excellent pictorial views and sections.

ELEMENTARY MENSURATION.

Elementary Plane and Solid Mensuration, for use in Schools, Colleges and Technical Classes. By R. W. Edwards, M.A. Pp. xxx + 304. (London: Edward Arnold, 1902.) Price 3*s*. 6*d*.

THIS book begins with an explanation of the nature and use of logarithms, followed by that portion of trigonometry which deals with a single angle and the application thereto of logarithmic calculation. Then comes a short chapter on calculations relating to parallelograms, and this is followed by one on triangles, wherein there is such further development of trigonometry as is required for the solution of triangles from the usual data. After this, rectilinear figures are treated of in the order of simplicity—trapeziums, regular polygons, &c. We have then a very useful little chapter on similar figures of various kinds, illustrated by a considerable number of numerical examples, followed by one on irregular rectilinear figures in general. Next follow calculations relating to the circle, illustrated by nearly ninety examples. Modern demands for the employment of squared paper and graphic representation are satisfied by a short chapter on graphs, and this leads to an exposition and application of Simpson's rule. After this comes the treatment of solids in the order of simplicity, and all the well-known rules are proved and illustrated by numerous examples. No rule is given without the proof, the author saying in his preface that

"students of elementary mensuration are frequently obliged to be content with a mere statement of the rules employed and with working out examples on these rules."

This was, no doubt, true of treatises written thirty or forty years ago, but it has ceased to be a true criticism of recent works. The mensuration of solids concludes with a long chapter on the sphere which will be a help to the student in his study of spherical trigonometry.

It will thus be seen that this book contains all that is necessary for the ordinary work of the surveyor and the engineer, and that, as regards the amount of knowledge

of logarithms, algebra and trigonometry required as a preliminary, the work is self-contained.

The author says in the preface that he would "like to have added chapters on surfaces of revolution, centroids and radii of gyration"—subjects which are usually confined to treatises on the integral calculus. It is high time, however, to take them out of the exclusive control of the severe exponents of pure mathematics and to bring them more into contact with practical needs by means of arithmetic. More especially is this true with regard to what are called "moments of inertia"—a term so wide of the thing intended to be signified that it is a perpetual stumbling-block to perception in the mind of the average student. What can be the meaning of the "moment of inertia" of a mere *area* about an axis? Is not the notion of a *mean square of distance*, whether of a material body or of a mere area, from an axis something the nature of which is more readily grasped and firmly retained than the ordinary term *square of the radius of gyration?* The *square root of the mean square of distance* is what is universally called the "radius of gyration." No doubt, the expression sounds strange at first to the student, but the strangeness rapidly wears off; and the notion of a *mean square*, whether of distances or of velocities, is one which so often occurs in various branches of physics that benefit to the student would result if a "radius of gyration" were presented to him in this way. The notion is one which preeminently lends itself to arithmetical illustration and treatment; it is found, for example, to work admirably with certain engineering students, and we commend it to the consideration of Mr. Edwards when he prepares the second edition of his useful work.

OUR BOOK SHELF.

Traité encyclopédique de Photographie. Third supplement. By Charles Fabre. Pp. 423. (Paris: Gauthier-Villars, 1902.) Price 10 francs.

THIS supplement constitutes the seventh volume of Prof. Fabre's work, and covers the period from the date of the second supplement, 1897, to May of the present year. On turning over its pages, one cannot but be struck by the very large amount of space devoted to apparatus. More than 230 pages are so utilised, while negative making has but 54, direct printing methods 41, and photo-mechanical methods 11. It is needless to add that while lenses, cameras, shutters, &c., are dealt with in full detail, the progress of photography itself is inadequately treated. Some important matters, concerning which one would naturally turn to such a work as this, are omitted, and others are only referred to. This tendency to neglect photography for the sake of photographic apparatus is more or less general in the larger treatises on the subject; perhaps, therefore, this kind of manual best meets the general demand. But it is difficult to understand why the photographic student should desire a full technical description of every variety of objective and be satisfied with little more than a popular summary of work done in the science itself. We know of no treatise that gives any approach to a complete survey of the science of photography. And seeing that the present position of the science is so largely due to work done during the last ten, or at most about twenty, years, the need for a comprehensive treatise written from our present standpoint is obvious.

The character of Prof. Fabre's work is too well known and appreciated to call for detailed reference in connection with a supplement. The author might perhaps have been a little more up to date in some respects. He might, for example, have stated that the Royal Photographic Society has at last withdrawn its unit of $f/4$ for lens apertures and recognised that the natural unit is $f/1$. On the other hand, he could not have recorded the similar step taken by the International Congress of Paris, as their acceptance of the natural unit was not announced until after the first part of the supplement was published. The table at p. 43, showing the various series of empirical numbers that have been used for indicating apertures, is therefore now almost wholly a matter of history.

Astronomy Without a Telescope. By E. Walter Maunder, F.R.A.S. Pp. xii + 272. (London: *Knowledge* Office, 1902.) Price 5*s*. net.

BY collecting these papers on "Constellation Studies," "The Zodiacal Light," and other subjects for the amateur astronomer, Mr. Maunder has directed attention to many interesting observations which can be made without instrumental aid.

The book is divided into three sections, (1) constellation studies, (2) astronomical exercises without a telescope, and (3) astronomical observations without a telescope; and it is illustrated by 44 charts and photographs, and 12 excellent star maps. The object of the book is to encourage naked-eye observations, and this is kept in mind throughout, though for some parts of the subject an ordinary field-glass is allowed.

In "Constellation Studies," the reader is introduced to the constellations and their units, an intimate knowledge of which the author counts a *sine qua non* in the prosecution of the exercises and observations mentioned in sections ii. and iii. This instruction is given in a readable and interesting form, and seems to deal with all the objects which are of interest to a naked-eye astronomer. With the aid of frequent quotations from Aratus and some of the ancient rhymesters, the historical and mythological allusions to constellation and star names are explained in an instructive manner.

In sections ii. and iii., the observer is given assistance for the *scientific* observation of some ten different astronomical phenomena. For instance, in the chapter on "Meteors," a list of questions is given which observations of the meteor should answer, and, further, the unnecessary, but usual, complicated remarks are indicated. In the chapter on "Auroræ," also, there are hints on what to look for and what to note; whilst such suggestions as an apparent connection between the apex of the "Zodiacal Light" and the Pleiades will encourage amateur astronomers to make patient and persistent observation. The chapter on "New Stars" indicates another field of possible usefulness.

With the exception of the introduction of "Columbia" for "Columba" on map 12, the book seems to be free from typographical errors, but we would express a regret that the names of the letters of the Greek alphabet, when used to designate a star, were not printed in a different type from that used for the *proper* names of the stars, because, despite the explanation of the alphabet given as an appendix, this is likely, at first, to form a stumbling-block to readers who are not familiar with the names of the Greek characters.

Aids to the Analysis and Assay of Ores, Metals, Fuels, &c. By J. J. Morgan, F.I.C., F.C.S. Pp. viii + 105. Students' Aids Series. (London: Baillière, Tindall and Cox, 1902.) Price 2*s*. 6*d*.

THIS little book is intended for the use of students and others to whom the more expensive standard works on analysis and assaying are inaccessible. It is entirely devoted to quantitative estimations, and some two hundred methods are concisely described. It contain

the assay of the ores of gold, silver, copper, lead, tin, zinc, iron, manganese and chromium, and the estimation of the impurities usually met with in these metals. There are also sections devoted to the analysis of fluxes, refractory materials, slags, fuels, &c., and of white alloys, iron alloys and copper alloys. This enumeration is enough to show that an enormous amount of ground is covered, and in such a small book there is, of course, no room to explain the principles on which the directions are based. The directions themselves, however, are clear and generally accurate. Among the mistakes and omissions which have been noticed, the neglect to reoxidise the lead reduced by the filter-paper in the ignition of lead sulphate and an erroneous method of calculating the gold contained in ores may be mentioned. The modern method of adding zinc acetate instead of soda and acetic acid in the iodide copper assay is not mentioned, and electrolytic methods generally are ignored. The book should be useful to students in polytechnics and other evening schools.

First Stage Mathematics. Edited by W. Briggs. Pp. vii + 186. (London: Clive, 1902.)

THIS volume of "The Organised Science Series" deals with the geometry and algebra required for Stage i. Mathematics in the South Kensington examinations. In section i., the text of Euclid i. is strictly followed, with occasional notes and explanations. Useful summaries of the propositions are given, also several sets of easy exercises and a number of miscellaneous riders. A few additional propositions are proved, and hints are given on writing out proofs.

In section ii. (algebra), in one or two places the reasoning does not appear quite satisfactory. For example, on the sign of a product, on p. 21:—"Suppose $+2\times-3$ or $-2\times+3$. Evidently the product will not be the same in either of these cases as in $+2\times+3$. Therefore we assume that $+2\times-3=-6$ and $-2\times+3=-6$. *Therefore, when one term has a plus sign and the other term has a minus sign the product is minus.* Again, suppose -2×-3. This is different from the last two cases, and we assume that $-2\times-3=+6$. Therefore, when two terms with minus signs are multiplied together the product is plus. From these results we can infer the rule of signs." A statement of this kind almost inevitably tends to fog the mind of a student.

The use of the word *sum* (as on p. 52) in any other than its exact algebraic meaning, in a text-book for beginners, is objectionable.

There are numerous easy exercises in algebra, also arithmetical questions from previous papers.

The book is well printed, and the figures in the geometry are clearly drawn.

Preparatory Lessons in Chemistry. By Henry W. Hill. Pp. v + 122. (London: Allman and Son, Ltd.) Price 1*s.*

THE order of treatment in this little book represents the method of teaching chemistry more common twenty years ago than now. Before being set to examine for himself easy familiar chemical changes in a scientific manner, the beginner is expected by the author to be able to understand such subjects as atoms and molecules, formulæ and equations, and similar matters much more suitable for students at a later stage of work. Several better books for beginners in chemistry are available.

My Dog Frizzie and Others. By Lady Alicia Blackwood. Pp. 44. (London: Operative Jewish Converts' Institution). Price 4*d.*

THESE are simple, interesting stories concerning the habits and character of a pet dog. The tales may encourage children to study animals intelligently.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Sound Waves and Electromagnetics. The Pan-potential.

THE photographs taken some years ago by Prof. Boys of flying bullets showed the existence of a mass of air pushed along in front of the bullet. Is there anything analogous to this in the electromagnetics of an electron? Suppose, for example, that an electron is jerked away from an atom so strongly that its speed exceeds that of light. Then it will slow down by reason of the resisting force to which I have shown it is subjected. So long as its speed is greater than that of light, it is accompanied in its motion by a conical wave. The question is whether there is any disturbance ahead of the electron, close to it, as in the case of a bullet moving through the air. It is a question of fact, not of theory. When Maxwell's theory shows that there is no disturbance in front of the electron, that is only because it is virtually assumed to be so at the beginning, by the assumption that the ether continues fixed when the electron traverses it.

Apart from this detail, the analogy between the conical sound wave and the conical electromagnetic wave is interesting in connection with C. A. Bjerknes's theory of pulsations in a liquid, as developed by V. Bjerknes in his "Vorlesungen über hydrodynamische Fernkräfte nach C. A. Bjerknes' Theorie." The liquid is incompressible, and is set into a pulsating state by pulsating sources, and the result shows remarkable analogies with electric and magnetic phenomena when they are static.

Now if the liquid is compressible, the results must be approximately the same provided the pulsations are not too quick. But if very rapid, and the compressibility be sufficient to lower the speed of propagation sufficiently, new phenomena will become visible with pulsating sources, like sound waves, and the question is how far they are analogous to electromagnetic phenomena?

Here, for example, is an interesting case. Let f be the density of the source, such that (if $q = d/d(vt)$),

$$(\nabla^2 - q^2)V = -f \qquad (1)$$

is the characteristic of the velocity potential V, so defined that $-\nabla V$ is the velocity. Then f signifies the amount of fluid (unit density) generated per unit volume per second and diverging outward. Then, for a point source of strength Q, the V it produces is

$$V = \frac{\epsilon^{-qr}}{4\pi r}Q = \frac{Q(t - r/v)}{4\pi r}, \qquad (2)$$

at distance r. This is equivalent to Rayleigh's account of Helmholtz's spherical waves from a centre ("Theory of Sound," vol. ii.), except in the interpretation of f or Q, which I do not altogether understand in that work.

Q is a fluctuating function of the time in the above in the acoustic application, though, of course, fluctuation is not necessary in the ideal theory. Now if the source Q moves through the air with velocity $\mathbf{u}$, the potential becomes

$$V = \frac{Q}{4\pi r\{1 - (u/v)\cos\theta\}}, \qquad (3)$$

if θ is the angle at Q between $\mathbf{r}$ and $\mathbf{u}$ at the proper moment.

This equation therefore expresses the theory of a very small pulsating source moved through the air, and is so far very like that of an electric charge Q (which does not pulsate) moved through the ether. The analogy does not continue in details, when, for example, we compare velocity with electric displacement. The electromagnetic theory is more involved.

When u exceeds v, equation (3) is no longer the complete solution. If u is less than v, there is just one and only one position of Q at a given moment where it is, so to speak, in communication with P, the point where V is reckoned. But when $u > v$, there may be just one point, or two, or there may be any number. Thus, if the source Q starts at moment $t = 0$ from a certain point, and then moves steadily in a straight line, the wave front is conical, with a spherical cap, or spherical, with a conical spike, Q being at the apex. If P is

inside the sphere, there is only one position for Q. But if P is inside the cone, there are two. The value of V at P is the same for both, given by (3) reckoned positive always. So the real V at P is double as much.

If the speed varies, the values of u will usually be not the same in the two positions, so the two partial V's must be separately reckoned. But the speed and path may vary in such a way that there are more than two positions of Q which are the centres of waves which all arrive at P at the same moment.

When there are any number of electrons moving about in given paths, the following will give a broad idea of the nature of the problem. To find V at a fixed point P at the moment t. Let at that moment a spherical surface expand from P at speed v, not forward in time, but backward. In expanding from radius 0 to ∞, it will cross the electrons one after another. Take note of the times of passage, t_1, t_2, &c. (less than t), of the charges and their velocities. Then

$$V = \Sigma \frac{Q}{4\pi R\{1 - (u/v)\cos\theta\}}, \qquad (4)$$

where $R_n = v(t - t_n)$, and θ_n is the angle at Q_n between $\mathbf{R}_n$ and $\mathbf{u}_n$. Similarly as regards the vector potential.

When u is allowed to exceed v, the effect is to increase the number of crossings of electrons. An electron crossed twice counts as two electrons.

The value of $\dot{t}_n$ is $\{1 - (u/v)\cos\theta_n\}^{-1}$. The vector $\mathbf{u}_n$ is the real velocity of Q_n at the moment t_n. Its apparent velocity, as viewed from P at the moment t, is $\mathbf{u}_n\dot{t}_n$ or $-\dot{\mathbf{R}}_n$. It has no necessary resemblance to the real velocity, and may be positive or negative. The dot here signifies differentiation to t at P.

Talking of potentials, I am tempted to add a few words about their King, the Pan-potential. In equation (1) above, let q be not $d/d(vt)$, but any sort of complex time differentiator, for example, if $p = d/dt$,

$$q^2 = (k + cp)(g + \mu p),$$

which is the special form for electromagnetic waves in a conductor. Then (2) is still the solution for a point source, and in general

$$V = \Sigma \frac{\epsilon^{-qr} f}{4\pi r} = \text{pan} f \qquad (5)$$

is the pan-potential due to the distributed source f. It is not the complete solution, because ϵ^{qr} has not been counted; but that is not wanted when there is no barrier to reflect.

For instance, if $\mathbf{C}$ is *impressed* electric current, in a conductor, the characteristic of $\mathbf{H}$, magnetic force, is

$$(\nabla^2 - q^2)\mathbf{H} = -\text{ curl } \mathbf{C}. \qquad (6)$$

It follows by the above that

$$\mathbf{H} = \text{pan curl } \mathbf{C}, \qquad (7)$$

that is, the magnetic force is the pan-potential of the curl of the impressed current. The operations pan and curl are interchangeable, so

$$\mathbf{H} = \text{curl pan } \mathbf{C}, \qquad (8)$$

i.e.,

$$\mathbf{H} = \text{curl } \mathbf{A}, \qquad \text{if} \qquad \mathbf{A} = \text{pan } \mathbf{C}.$$

(Similarly ∇ pan = pan ∇, and div pan = pan div.)

I worked out this problem for a fixed point source of impressed current some time ago ("Elec. Pa.," vol. ii. p. 432) without reference to the pan-potential. The operational solution there given, equation (258), represents either (7) or (8). The algebrisation was also done. There is no advantage in using the $\mathbf{A}$ function in this particular case; it is, in fact, more difficult to find $\mathbf{A}$ first and then derive $\mathbf{H}$ than to obtain $\mathbf{H}$ without $\mathbf{A}$. Similarly as regards $\mathbf{E}$, the electric force. The second circuital law derives it from the $\mathbf{H}$ equation, so that it is not required to introduce Φ to supplement $\mathbf{A}$.

If the point-source is in motion, the pan-potential requires Dopplerisation as well as the ordinary potential. But this does not require explicit representation for continuously distributed sources. For example, the electromagnetic circuital equations

$$\text{curl } (\mathbf{H} - \mathbf{h}) = \mathbf{u} \text{ div } c\mathbf{E} + (k + cp)\mathbf{E}, \qquad (9)$$

$$\text{curl } (\mathbf{e} - \mathbf{E}) = \mathbf{w} \text{ div } \mu\mathbf{H} + (g + \mu p)\mathbf{H}, \qquad (10)$$

where $\mathbf{u}$, $\mathbf{w}$, $\mathbf{e}$, $\mathbf{h}$ are functions of position and time, have the solutions

$$\mathbf{E} - \mathbf{e} = \text{pan } \mathbf{X}, \quad \mathbf{H} - \mathbf{h} = \text{pan } \mathbf{Y}. \qquad (11)$$

To prove this, and determine the nature of $\mathbf{X}$ and $\mathbf{Y}$, it suffices to put the characteristics of $\mathbf{E} - \mathbf{e}$ and $\mathbf{H} - \mathbf{h}$ in the form (1), q^2 having the more general later meaning. Now (9) and (10) lead to

$$(q^2 - \nabla^2)(\mathbf{E} - \mathbf{e}) = \nabla\rho - \text{curl } \mathbf{G} - (g + \mu p)\mathbf{C}, \qquad (12)$$

$$(q^2 - \nabla^2)(\mathbf{H} - \mathbf{h}) = -\nabla\sigma + \text{curl } \mathbf{C} - (k + cp)\mathbf{G}, \qquad (13)$$

where

$$\rho = \text{div } (\mathbf{E} - \mathbf{e}), \quad \sigma = \text{div } (\mathbf{H} - \mathbf{h}), \qquad (14)$$

$$\mathbf{C} = \mathbf{u} \text{ div } c\mathbf{E} + (k + cp)\mathbf{e}, \qquad (15)$$

$$\mathbf{G} = \mathbf{w} \text{ div } \mu\mathbf{H} + (g + \mu p)\mathbf{h}. \qquad (16)$$

So $\mathbf{X}$ and $\mathbf{Y}$ are the right members of (12) and (13) as defined. $\mathbf{C}$ is the impressed electric current, $\mathbf{G}$ the impressed magnetic current. It will be seen that no separate determination of scalar potentials is required, because they are already included in $\mathbf{X}$ and $\mathbf{Y}$.

OLIVER HEAVISIDE.

Recent Dust Storms in Australia.

ON November 11, 12 and 13, 1902, New South Wales and Victoria experienced severe dust storms, apparently caused by a mild cyclone travelling from the west, as the dust reached here yesterday morning, the wind at the time being very light. The atmosphere was so loaded with fine dust that the sun looked dim and objects less than a mile away were quite indistinct, and all furniture, even with doors and windows closed, became coated with a fine grey deposit.

Reports from vessels coming along the coast say that the sea had a peculiar leaden colour; and a remarkable appearance was seen in Sydney Harbour yesterday morning. Crossing the harbour from the north to the south side, immediately on getting in sight of the sun the wavelets between the steamer and the sun showed streaks of brilliant light metallic blue colour. This was intensified when the boat entered the still glassy water of Sydney Cove, when the back of each ripple caused by the steamer on the sunny side showed a sheet of the same colour and that most brilliantly. The water where undisturbed was covered by a slight scum, which might either be settled dust or a layer of mineral oil, but appeared more like the former. The colour had not the iridescent appearance caused by oil, as it was a uniform pale blue and only showed on the back of the wavelets.

It seemed to me that this was an exaggerated example of the blue colour of water caused by finely-divided mineral matter seen in glacier waters and those of the hot lakes of New Zealand, where the water has silica in suspension.

WILL. A. DIXON.

97 Pitt Street, Sydney, November 14, 1902.

ABOUT half-past four o'clock on the afternoon of November 12, I noticed that the sky to the north and north-east, from the horizon half-way to the zenith, had assumed an extraordinary chocolate-brown tint, due to clouds of that colour which were moving towards us from the north-west. Under these clouds, and moving from the north-east, were ashy-grey patches of stratus, streaked with fantastic dark lines resembling bows and boomerangs. A few drops of rain which fell about five o'clock were charged with brown, earthy matter, and at six o'clock a paper which was held in the rain became spotted all over with brown blotches.

This fact, and the colour of the clouds, led me to the conclusion that a tornado had taken place in the interior of Australia, whirling the fine dust high into the upper regions of the atmosphere, in which position it was carried over the Straits and then descended with the rain.

At 6.20 p.m. the solid matter was still descending, but in less quantity; at 6.30 there was a marked diminution; and by ten minutes to seven the rain was all but free from it.

While the six o'clock shower was descending, one heard the remark on all sides that "it was raining mud"; those who were unfortunate enough to have their week's washing hanging out at the time were doomed to a second day at the wash-tub.

This remarkable occurrence recalls the events of Black Thursday, 1851, when Victoria was swept by tremendous bush-fires; leaves and portions of charred ferns were carried up to great heights by the currents of heated air, wafted across Bass' Straits and deposited upon our shores; the sky was so darkened by huge volumes of smoke that, although in the height of summer, lamps had to be lit early in the afternoon.

H. STUART DOVE.

West Devonport, Tasmania,
November 14, 1902.

A Sickle Leonid.

AT 2h. 17m. on Sunday morning, December 21, I witnessed the passage of a swift, streak-leaving meteor, magnitude 1, duration about 0·75 second. It proceeded from γ of Cancer and disappeared near to λ of Gemini. On tracing its path backward, I found its radiant to be in the well-known Sickle of Leo.

G. MCKENZIE KNIGHT.

25 Holford Square, London, W.C.

THE BABYLONIAN AND ASSYRIAN LEGENDS OF THE CREATION.[1]

IT is now a little more than thirty years ago since the learned world was startled by the announcement that Assyriologists had discovered a remarkable version of the history of the Creation, which closely resembled the narrative of the first chapter of the Book of Genesis, and appeared to be based upon the archetype from which one of the earliest editors or writers of the Pentateuch drew many of his statements. The interest shown in the discovery of the Babylonian and Assyrian account of the Creation was widespread, and though it did not equal that displayed by the learned world in the story of the Deluge as unfolded from the cuneiform records by the late Mr. George Smith, it was sufficiently important to move Assyriologists to further exertions and to provide them with a public which has been ever ready to welcome the results of their labours with toleration and praise. The credit of the discovery of the cuneiform Creation records in the British Museum belongs, undoubtedly, to Sir Henry Rawlinson, and it must even be a subject for lament that his official occupations prevented him from laying his work before the world in a suitable manner many years before his assistant, Mr. George Smith, was able to do so. In the preface to the work before us, Mr. L. W. King, of the British Museum, has continued, and, we are glad to add, completed, as far as is possible at present, the work which was begun by Sir Henry Rawlinson, and he presents to us the whole of the available material in a form handy to use and easy to study.

The first volume of the "Seven Tablets of Creation" contains a useful preface, a good introduction, and transliterations into English letters of all the cuneiform texts, with clear translations arranged opposite them; five appendices, an index and a glossary complete the volume. In the second half of the work, we have the original cuneiform texts, and as they are written in a good, bold hand, the curious reader will find no difficulty in verifying any of Mr. King's statements. After sketching briefly the services which have been rendered by earlier editors of the Creation legends, Mr. King passes on to describe the new material which he has found as the result of several examinations of the collections of clay tablets from Kuyunjik now in the British Museum. In the thirteenth part of "Cuneiform Texts," published by the Trustees of the British Museum in 1901, Mr. King gave copies of a number of documents relating to the Creation, among them being several which, though used by previous workers, had not been published, and one which had been consulted by Mr. Smith in 1876, but had been apparently lost sight of. Great credit is due to Mr. King for identifying this last-mentioned important fragment, for, so far as we have been able to discover, it was not recognised by Dr. Bezold, who, in his "Catalogue of the Konyunjik Collection" (p. 998, K. 9267), describes it merely as "part of a mythological legend." Whilst, however, Mr. King was searching for fragments of other Babylonian legends, he discovered so many new portions of the Creation legends and duplicates that he decided to write a monograph on the subject, and as the result of his labours we are now able to form a connected idea of the whole of the Babylonian story of the Creation. Formerly, only twenty-one tablets and fragments inscribed with portions of the legend were known, but now no less than forty-nine separate tablets and fragments have been identified as containing portions of the cuneiform texts of the Creation series. In fact, Mr. King has identified twenty-eight new portions and duplicates of Creation texts, and the details of the great story can now be followed consecutively, a thing which, up to the present, has been impossible.

We now know that the great Babylonian poem of Creation was divided into seven sections, or tablets, and that the whole work was known by the title "Enuma Elish," which also forms the opening words of the text,

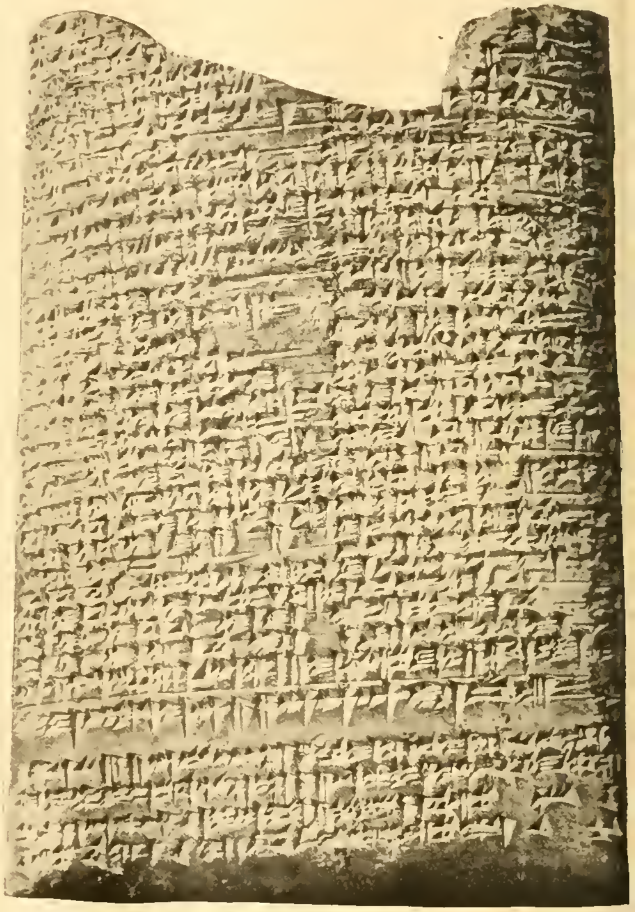

FIG. 1.—Part of the Fourth Tablet of the Creation Series (Brit. Mus., No. 93,016).

and that it contained nine hundred and ninety-four lines; those who are interested in ancient theories of numbers will note that 994 is a multiple of 7. Each of the seven sections on tablets contained, on an average, one hundred and forty lines, and it is clear that each tablet was intended to describe the events of one "day" of creation. It is difficult not to think that such artificial divisions of the legend indicate that we are dealing with a comparatively late recension of it, and this may well be the case when we remember that the oldest copies of it which we possess date from the reign of Ashur-bani-pal (B.C. 668-626); no one who takes the trouble to read the seven tablets and who is familiar with ancient cosmogonies and theogonies will have the slightest doubt that

[1] "The Seven Tablets of Creation." By L. W. King. Vol. i. English translations. Pp cxxiv + 274. Vol. ii. Pp. xiii and 84 plates. (London: Luzac, 1902.)

the original form of the Babylonian and Assyrian history of Creation is many thousands of years old. Whether it originated with the Akkadians or some other non-Semitic people cannot be said definitely at present, but it is very probable that the Semitic Babylonians were only the borrowers and not the inventors of this remarkable work.

We may now note the main heads of the legend. At the beginning of all things, Apsû and Tiamat were water deities and typified chaos; to these were born Lahmu and Lahamu, and later appeared Anshar and Kishar, and still later Anu and other gods came into being. One of the newly-found fragments of the first tablet mentions the birth of Nudimmud (Ea), and although Damascius states that Bēl, the creator of the world, was the son of Ea and Damkina (Ἀός, Δαύκη), it is clear from the fragment that Marduk, who is made to take the leading part in the later tablets of Creation, was supposed to be in existence, like Mummu and Gaga. In the earlier episodes of the Creation story, it is Ea and not Marduk who is the hero, and we learn for the first time, from the new material, that it was Apsû, a god of chaos, and not Tiamat who rebelled against the gods. Apsû disliked the new order of things and the creation of the universe for the simple reason that the beings who formed members of the new world disturbed his peace and rest; as soon as he had made up his mind as to what was likely to happen, he called Mummu his minister (the Μωϋμὶς of Damascius), and the two went to Tiamat and took counsel with her, and complained that "he could get rest neither by day nor by night." The putting of the house of the world into order by the gods destroyed his rest and peace of mind. Of the conflict which took place between Ea and Apsû and his ally Mummu we know little, but that the great god did not succeed in inflicting a decisive defeat on Apsû and his allies is clear from the fact that, later, Anshar found it necessary to exhort Marduk to do battle with Tiamat. Of the defeat and death of Tiamat we need say little, for the story of how the god of light slew her and split her body into halves is familiar to all. The actual account of the creation of the world by Marduk begins towards the end of the fourth tablet, where it is said that one-half of the body of Tiamat formed a covering for heaven, and that Marduk, having formed E-shara, made the great trinity of Anu, Bēl and Ea to dwell therein.

In the fifth tablet, we hear of the fixing of the constellations of the Zodiac, the founding of the year, &c., and it seems as if this section contained an account of the creation of vegetation. The sixth tablet, as we know from one of the new fragments, told the story of the creation of man, and it seems as if Marduk made man with the view both of punishing the gods and of providing a creature who should at all times worship him. Marduk, or Bēl, instructed Ea to cut off his (*i.e.* Marduk's) head, and man was formed out of the blood which flowed from the god's body. Marduk is made to tell Ea that he intends to create man from his own blood and from the "bone" which he will create; it is important to note that the Assyrian word for "bone" is *issimtu*, and that it is the exact equivalent of the Hebrew *'esem*, "bone," which occurs is Genesis ii. 23, in connection with the account of the creation of woman.

The creation of man was the final act of creation, and when this was accomplished the gods assembled in their council chamber in Upshukkinaku, with Marduk at their head, and they sang to him a hymn of praise, the text of which forms the seventh section of the Creation story and contains fifty addresses to the god. How Marduk managed to survive his decapitation is not told us, and we can only surmise that he met the gods in their council chamber in some sort of spiritual body. The space at our disposal will not allow us to call attention to many very interesting details of the legend, especially in the parallels which may be drawn between parts of it and the Book of Genesis; these prove beyond all reasonable doubt that the Jews borrowed large portions of their religious literature from their kinsmen the Babylonians, and that the seven days of Creation were imagined long before the days of the patriarch Abraham. The student of comparative folklore will find much to interest him in Mr. King's latest work, and will perhaps trace the mingling of legends illustrated in it with somewhat mixed feelings. Mr. King's texts are carefully edited and well copied, and his translations, which we have examined in several passages, are faithful and not unduly literal, and his work is a credit to English Assyriology.

A POT OF BASIL.

THERE is a widely spread belief, both amongst natives and amongst the white sojourners in Western Africa, that the presence of a certain species of plant in a room drives away mosquitos, and, in fact, a single plant is said to be sufficient to clear a room. On his recent return from Northern Nigeria, Major J. A. Burdon, of the Cameron Highlanders, brought with him and gave to me a few leaves of this plant. These, through the kindness of Mr. H. H. W. Pearson, have been identified by the experts at Kew as belonging to *Ocimum viride*, Willd., a member of the order Labiatæ, which occurs from Senegambia southwards to Angola.

Major Burdon, who is Resident of the Nupe Province, Northern Nigeria, and Hausa Scholar of Christ's College, Cambridge, has given me the following account of the plant:—

"A fragment of what turns out to be *Ocimum viride* was given me in August last at Lokoja, Northern Nigeria, by Captain H. D. Larymore, C.M.G., R.A., Resident of the Kabba Province. Capt. Larymore's notice had been drawn to the plant by a native living in a low-lying part of the native town at Lokoja, who had told him that the natives suffered very little from the swarms of mosquitos which existed in that part, as they protected themselves from them by the use of this plant.

"Capt. Larymore made inquiries and obtained a few specimens of the plant, which grows wild, though not very abundantly, in the neighbourhood of Lokoja. These specimens he planted in pots and boxes and kept in and about his house. The specimens I saw were about the size of a geranium.

"He informed me that the presence of one of these plants in a room undoubtedly drove the mosquitos out, and that by placing three or four of the plants round his bed at night he was able to sleep unmolested without using a mosquito net. This is very strong testimony to the efficacy of the plant, for the house in which Capt. Larymore was living is, as I had cause to know well in former years, infested with mosquitos."

In the fifth volume of Sir W. T. Thiselton-Dyer's "Flora of Tropical Africa," *Ocimum viride* is described as follows:—

"*O. viride*, Willd.; Benth. in DC. Prod. XII. 34. A perennial 3–6 ft. high, with much-branched glabrous stems. Leaves distinctly petioled, oblong, acute, membranous, 3–4 in. long, glabrous on both sides, or obscurely pubescent beneath. Racemes lax, copiously panicled, 3–6 in. long; rhachis finely pubescent; bracts deciduous; pedicels not very short. Calyx $\frac{1}{6}$ in. long; tube campanulate; upper lobe orbicular, as long as the tube; lower teeth short. Corolla half as long again as the calyx-lobes. Stamens but little exserted, the two upper with filaments toothed above the base.—Benth. in Hook. Niger Fl. 488; Henriques in Bolet Soc. Brot. X. 149. *O. febrifugum*, Lindl., in Bot. Reg. t. 753. *O. heptodon*, P. Beauv. Fl. Owar. II. 59. t. 94."

The plant is figured on plate 753 of the ninth volume

of the Botanical Register, 1823, under the name *Ocymum febrifugum*, or the "Sierra Leone Fever Plant." This work mentions that the plant is "in request at Sierra Leone for medicinal purposes," and describes the species as an "*under shrub* 3 feet high," "having in a high degree the smell of common balm."

The leaves of the plant are highly glandular, and in India an allied species, *O. Basilicum*, Linn., the "common sweet basil," produces a "yellowish green volatile oil lighter than water, which, on being kept, solidifies into a crystalline camphor, isomeric with turpentine camphor" (*Gmelin's Handbook*, xiv., 359).[1] The seeds of this species are widely used in the

FIG. 1.—*Ocymum viride*, Willd. Some leaves drawn from a dried specimen brought back by Major Burdon. Below is a raceme of the same plant taken from the "Botanical Register," vol. ix. Both reduced.

east as a medicine, and their properties "are said to be demulcent, stimulant, diuretic and diaphoretic." "The juice of the leaves mixed with ginger and black pepper is given in the cold stages of intermittent fever." The leaves, like those of thyme, are used as a seasoning in cooking. Another Indian species, *O. sanctum*, Linn., the "sacred basil," is the most sacred plant in the Hindu religion, and is consequently widely cultivated.

In "Notes on the Medicinal Plants of Liberia,"[2] Mr. E. M. Holmes records that when chewed or rubbed, the leaves of *O. viride* give off a strong odour of lemon thyme, and mentions that Dr. Roberts, of Liberia, entirely substituted the use of the plant for that of quinine in cases of fever of all kinds, giving it in the form of an infusion.

There is thus a good deal of evidence that *O. viride* is a plant of considerable curative value, especially in cases of fever, but the question that interests a large number of people in West Africa is whether it is equally efficacious as a preventative. Does it really repel the mosquito which acts as the intermediary in conveying the malarial hæmatozoon from man to man? Further experiment on this point is needed, but there is at least some indication that in this easily cultivated plant man has another weapon with which to fight malaria.

Christ's College, Cambridge. A. E. SHIPLEY.

TRANSATLANTIC WIRELESS TELEGRAPHY.

THE announcement of the successful inauguration of the Transatlantic wireless telegraphic system which we were able to make last week must have come as welcome news to all, but hardly as a surprise to those who have followed with any closeness Mr. Marconi's persevering experiments. Those who have done so and who have seen how, in almost every instance, Mr. Marconi has achieved all that he has said he would achieve can hardly have doubted that in this case also he would be successful. And when once it had been demonstrated that Hertz waves were capable of bridging the enormous distance from the Old World to the New, it was evidently only a matter of time to instal suitable stations on both sides of the Atlantic and to put them in operation. Nevertheless, the greatest interest attaches to the transmission of the first messages; one cannot help feeling that it is an historic occasion, not only marking an era in the development of wireless telegraphy, but also forging another link between this country and her colonies, and adding yet one more to the many benefits helping forward civilisation which science has conferred on mankind.

As yet, of course, not much has been done; a few congratulatory telegrams have passed from one side of the Atlantic to the other, and doubtless there will have to be much more experiment and work before a commercially useful system of communication is established. But for this we can wait in patience and confidence. It is easy to see that, though the possibilities are many and great, the difficulties also are formidable and numerous. In the first place, before the system can be commercially important, it is clear that the public must be made to feel confident that it is absolutely trustworthy; any uncertainty in this respect would be fatal to a system which has to make its way against the competition of existing methods. Again, the system is, for the present at any rate, limited in its carrying capacity, since the speed of signalling obtainable is not very great, and from what can be gathered it seems unlikely that multiplexing to any great extent, or even at all, can be regarded as a possibility of the near future. From another point of view also difficulties present themselves, for we have yet to learn what effect will be produced on existing wireless installations by a constant stream of very powerful Hertz waves sent out on either side of the Atlantic. If the Transatlantic signalling seriously interferes with the less pretentious applications of wireless telegraphy, there can be little question as to which it is more desirable to retain. But all these problems we may safely leave for the present, for we know that they are in the hands of one who has shown himself fully competent to deal with them.

Whatever else may be said of his present achievement, all must agree that it is a great personal triumph for Mr. Marconi, and one that he has fully merited by his untiring

perseverance and endeavour in the face of difficulties, opposition and adverse criticism that would have daunted many. Great indeed as the advances in wireless telegraphy have been when regarded simply as advances in applied science, few things are more remarkable than the rapidity with which they have been made. It is less than ten years since the first experiments were made in the application of Hertz waves to signalling. Mr. Marconi himself began work a few years later—in 1896. In that year he was able to transmit signals over a distance of a mile or so, and ever since he has been steadily increasing the limit until, about one year ago, it was announced that the signal "S" had been transmitted from Cornwall to America. Many who were sceptical of this result at the time must have been convinced of its genuineness when a little later (last March) messages were transmitted to the *Philadelphia* up to a distance of 1551 miles from land and the signal "S" transmitted to a distance of 2099 miles. Following on this came the cruise of the *Carlo Alberto* during July, August and September last, when extremely successful results were obtained over great stretches of land and water. Finally, at the close of 1902, we have the inauguration of a complete Transatlantic system with transmission of messages in both directions. No one can consider this as other than a splendid record for six years' work.

Little need be said of the stations on either side of the Atlantic, since both have been already described and illustrated in NATURE (see vol. lxv. p. 416, and vol. lxvi. p. 485). It is to be hoped that before long we shall be able to record that both have been in continuous and successful commercial working without producing any ill effects on other installations. When this has been accomplished, the problem of syntony remains to be solved, and we wish Mr. Marconi the same complete success in dealing with this problem as has crowned his other efforts. MAURICE SOLOMON.

A SUB-TROPICAL SOLAR PHYSICS OBSERVATORY.

WE have received from a correspondent in America the following letter by Prof. S. P. Langley, secretary of the Smithsonian Institution, suggesting the establishment of a great solar observatory in or near the tropics. Referring to the practical value of such studies of the sun as are suggested by Prof. Langley, our correspondent remarks:—"It is an amazing thing that the enormous utility of recent work on the sun's connection with the conditions which bring famine or plenty to India, for instance, is lost sight of by almost all astronomers. Astronomers and astrophysicists, even, are apt to look at it in its purely scientific interest, as if it had none other than what it might share with the discovery of the motion of a nebula."

The letter sent by Prof. Langley to the Hon. Charles D. Walcott, secretary of the Carnegie Institution, is given in the report of the executive committee to the trustees of the Carnegie Institution, published November 26, 1902, and reads as follows:—

February 28, 1902.

DEAR MR. WALCOTT,—You were saying to me that you knew of some persons who might be desirous of aiding, through the Smithsonian Institution, some large object, and I was led to write you what is in substance the following letter:

I learn from yours of February 14 that you would like to call it to the attention of the executive committee of the Carnegie Institution, and, as I have written, I shall be very glad to have you do so, asking you to make it clear that it is in no way a request from the Smithsonian Institution, but a suggestion from me of a great object which Mr. Carnegie himself may care to take up.

I do so the more readily because, considering the Institution wholly apart from its own needs, it would be the glad means of indicating to those who wish some worthy aim for expenditure, some specific object, which may be undertaken if desired *in their own name* and through any worthy medium they prefer.

One of these is the determination of the heat the sun sends the earth and the causes of its probable variation. The progress of solar physics has been such in the last few years as to make it of interest to every inhabitant of the planet that this progress should be carried further, not only in scientific, but in economic, and in even humanitarian interests.

The establishment of a great observatory in the tropical or sub-tropical regions at a high altitude would advance our knowledge of the heavenly bodies in a degree more than could be done by all the physical observatories in the world united. To the founder of such an observatory there would be enduring fame, but it is an affair of a very great deal of money, possibly to be reckoned only in millions. The establishment and maintenance for eleven years of a distinctly solar observatory under these conditions would enable us to study the sun as it has never yet been studied, and through an entire solar cycle, for much less cost.

While this latter research, then, is to be pursued at less cost than the foundation of a great general observatory, it has a specific object of literally world-wide importance and interest.

The determination of the heat the sun sends the earth annually is the determination of that through which everything on the planet lives and moves, and almost unknown slight variations of this heat are the probable, if remote, cause of the changing character of the seasons and of the lack or plenty in the crops upon the earth as a whole.

It has seemed possible within the last few years that if we had this knowledge, the years of plenty and of famine could be forecasted as we now forecast a coming storm through the advices of the Weather Bureau. It is possible, I say, but I do not wish to say more than that it is possible.

I do not know any greater or more worthy object for the expenditure of 500,000 dollars than the settlement of this latter great question would be. It is, with our present knowledge, almost a question of money; but no Government is prepared to spend such a sum except for its own interest. This is for the interest of all the people in the whole world, and I entirely concur with the recommendation of its importance from the chief of the United States Weather Bureau, which I enclose. I should gladly see it undertaken, whoever does it.

Very truly yours,

S. P. LANGLEY.

The Honorable CHARLES D. WALCOTT.

In a further letter, sent on October 20 to Prof. G. E. Hale, who asked for details of the proposed scheme of work and equipment, Prof. Langley described the principal objects of inquiry of a distinctly solar observatory, the plan of observations, and apparatus and accessories required.

NOTES.

THE management of the Imperial Institute will from January 1 be vested in the Board of Trade, assisted by an advisory committee representing various Government Departments and the Indian and Colonial Governments. The Board of Trade has appointed Prof. Wyndham Dunstan, F.R.S. (now director of the scientific and technical department of the Institute), to be Director of the Imperial Institute. Prof. Dunstan will continue in charge of the scientific investigation of economic products, and will supervise any other branches of work carried on by the Board of Trade in the building at South Kensington, including the collections of products of the Empire so far as they will be under the control of the Board. These arrangements do not affect the parts of the collections and the information offices under the special charge of representatives of the India Office and of certain Colonial Governments.

IN consequence of the presentation of a memorial in favour of the admission of women to the fellowship of the Linnean Society, the council issued a circular in March last inviting an expression of opinion on the part of the whole body of fellows. The result has been that 301 fellows have pronounced in favour

of the proposal and 126 against it, whilst 313 fellows gave no reply. This expression of opinion is considered sufficient to justify further action; accordingly the matter will be brought before a special general meeting on January 15. As the existing charter gives no power to the society to admit women as fellows, a resolution will be moved to obtain a supplemental charter for this purpose.

IN consequence of frequent cases of sickness and death caused by poisonous substances in salted raw fish used for food, the committee of the Caspian fishery and seal industries several years ago offered a prize for the investigation of the nature of the fish-poison, for indications of the methods of preventing fish from becoming poisonous, and for the healing of persons poisoned by fish. The accumulated interest and capital now amount to 7500 roubles (about 1050*l.*). The Imperial Academy of Sciences, St. Petersburg, acting with the Ministry of Agriculture and Crown Domains, have now issued particulars of a new competition on the nature of fish poison and the antidotes. The persons competing for the award offered in the interest of public health will be expected to offer solutions of the following problems:—(1) By careful experiments to define the qualities of poison contained in fish; (2) to investigate the action of the poison of the independent organs of animal bodies, the central nervous system, the heart, the circulation of blood and the digestive organs; (3) to present an accurate illustration of the pathological reactions in the various parts of animal and human bodies caused by such poisoning; (4) to present a description of the signs serving to distinguish fish containing poison from normal fish; (5) to indicate methods for the prevention of development of poison in fish; (6) to indicate antidotes and general provision against poisoning by fish. The awards for the competition will be three premiums, viz. 5000 roubles (700*l.*), and two of 1500 roubles (210*l.*) and 1000 roubles (140*l.*). The two lesser prizes may be gained should the author solve only a part of the problem, basing his experiments upon one method of science—chemistry, physiology or bacteriology. As regards the larger prize, this will be awarded only for the work which covers the problem of the nature of the fish-poison in all respects. The work sent in to compete for the awards may be written or printed in Russian, Latin, French, English or German, and should be submitted by October 1, 1903, to the Ministry of Agriculture and Crown Domains.

MR. N. F. DOBRÉE, of Beverley, has presented his collection of European Noctuæ to the Hull Municipal Museum. This collection contains more than five thousand specimens and is one of the finest in the country.

THE death is announced of Prof. Richard Baron Von Krafft-Ebing, professor of psychiatry at Vienna and author of works on psychiatry and physiological psychology.

WE regret to announce that Mr. Otto Hilger, the well-known astronomical and optical instrument maker, died on December 18, at fifty-two years of age.

MR. A. CARNEGIE has expressed to the Provost of Greenock his willingness to present to a properly authorised authority in the town the sum of 10,000*l.* to defray the cost of the erection of a memorial to James Watt; or he is willing to head a movement in America to raise a large fund which, added to what might be subscribed in Great Britain, would enable a wider scheme for a memorial to be arranged.

ONE of the subjects discussed at the recent conference of Colonial Premiers was that of an Imperial Patents Act whereby one patent would cover the whole Empire. Mr. G. C. Douglas, writing to the *Times* of December 30, points out that such a measure would help enormously in the building up of industrial concerns. In the United States of America, one patent covers a territory with an industrial population of about seventy millions, whereas it takes about forty patents to protect an invention in the British Empire. If it were decreed that one patent covered Great Britain, India and the various other dependencies, our great self-governing Colonies would probably soon unite with the Government to make the reform an Imperial one.

A REUTER telegram from Syracuse states that shortly after eight o'clock in evening of December 28 a severe shock of earthquake was felt, preceded by subterranean rumbling.

A REUTER telegram from St. Thomas on December 27 reports that a violent eruption of Mont Pelée was in progress at 10.30 that morning. Dense grey smoke and dust were pouring out to a great height. Advices from other sources state that the cone of the volcano was luminous at night.

PROF. LACROIX, the conductor of the French scientific expedition sent to Martinique, has, *La Nature* says, reported to the Colonial Minister an account of the consequences of the shattering of the cone formed in the crater of Mont Pelée. Blocks of incandescent lava rolled in the direction of the White River and filled it. Volcanic material six kilometres from the crater, which had collected in the neighbouring valley, had eight days after the eruption a temperature exceeding 100° C. On December 15, symptoms premonitory of an eruption were experienced at Kingston, St. Vincent, and on December 18 a new eruption occurred, but caused no accident.

A REUTER'S telegram from the scene of the recent earthquake at Andijan, dated December 23, states that the shocks continue and are daily increasing in violence.—December 26, *Ashkabad.* Oscillations of the earth are still noticeable. In Andijan and neighbourhood, 15,000 houses have been destroyed. Andijan as a town has existed for 400 years, and has already been visited by earthquakes.—December 28, *Ashkabad.* A long and violent earthquake shock was felt at Andijan at 10 p.m. yesterday.—December 29, *St. Petersburg.* The earthquake at Andijan on December 16 extended over an area of nearly seven hundred square miles. The epicentrum of the disturbance has been located about four miles to the south of Andijan. It is indicated by a rent made in the earth from which sand, water and mud are thrown up. The statical wave was about 28 inches high, and took a northerly direction.

WE learn from *Science* that Prof. H. V. Hilprecht has been awarded the Lucy Wharton Drexel medal of the University of Pennsylvania for his archæological researches.

AT the concluding meeting of the Egyptian Medical Congress on December 24, it was held that the international rules applying to plague and cholera required revision, and the wish was expressed that an international congress should meet forthwith to lay down rules in accord with the demands of science.

WE learn from *Science* that the Carnegie Institution of Washington has made a grant of 500 dollars to Prof. Bancroft, of Cornell University, for a systematic study of the bronzes; an annual grant of 10,000 dollars to revive the "Index Medicus," formerly published under the direction of Dr. J. S. Billings; and a grant of 1000 dollars to the astronomical department of Vassar College to enable Dr. Caroline E. Furness to make measurements and reductions of photographs of the stars in the region of the north celestial pole.

AT the dinner on December 22 to Major Ronald Ross, in honour of his being awarded the Nobel prize, the Lord Mayor of Liverpool dispatched a telegram to the King. The following message was received in reply:—"I have submitted your telegram to the King and I am commanded, in reply, to request you to congratulate Major Ross on the honour which has been conferred upon him by the King of Sweden.—KNOLLYS."

AN expedition sent by the New York Botanical Garden to Nova Scotia and Newfoundland has secured, the *Scientific American* states, 12,000 specimens of more than 2000 species of plants. A third of the specimens are marine plants. Another expedition sent to north Montana by the same enterprising institution has done much in the interest of scientific botany. Many alpine forms of plants were discovered. Ample statistics were secured establishing the variation of plant life caused by temperature and latitude, and of the general vertical distribution of flora.

REFERRING to Mr. Backhouse's letter on sunset glows in last week's NATURE (p. 174), the Rev. G. J. Bridges, writing from Salisbury, says:—"In addition to the colour growing less vivid, the 'colouring' does not occupy so much space as in the Krakatoa glows. It occurs much sooner after sunset and much nearer sunrise than in the case of those which occurred in 1883. . . . The dust wisps are so much more defined of late that it is difficult to distinguish them from faint streaks of strata except by position, which appears to be always horizontal and corresponding to the curvature of the earth."

IN most of our colonies, more particularly those which are concerned with agriculture, the official botanical staff is no longer considered to be complete without a specialist in plant diseases. The reports and pamphlets embodying the researches of these specialists bear evidence of valuable and important work. An account of the fungus diseases which attack stone-fruit trees in Australia has been prepared by Mr. D. McAlpine. The principal diseases are described at some length and illustrated with very excellent coloured plates. These present diagnoses suited to the farmer whose scientific knowledge is limited, and methods of treatment are suggested and explained. Besides, there is added an account of many less common fungi also destructive to trees bearing stone-fruit, which presupposes a certain amount of botanical training.

THE report of the Director of the Botanic Gardens, Sydney, N.S.W., for 1901, besides dealing with matters appertaining to the Botanic Gardens, includes the improvements effected in the various public gardens which come under his control. An event of considerable importance was the opening of new buildings which had been erected in order to accommodate the National Herbarium and provide space for a botanical museum. The latter occupies one of three large rooms, while the other two are set apart for the cryptogamic and phanerogamic herbaria respectively. An interesting feature of the museum is a collection of local plants; also due prominence has been given to characteristic Australian plants, such as the Acaciæ, Eucalypti, various genera of the Proteaceæ, and Coniferæ. Reference is made to the trees planted by their Royal Highnesses the Duke and Duchess of Cornwall and York on the occasion of their visit to Sydney.

MR. F. C. CONSTABLE directs attention to the serious disadvantages of the common practice of hanging on the walls of schoolrooms maps of various countries of widely differing areas, all drawn to different scales, with the result that the countries appear, approximately, of the same size. One of the direct consequences of this custom is that comparatively few educated persons can give the relative sizes of, say, England and Africa, of Canada, Australia and British India, with any approach to accuracy. This defect in geographical teaching is by some teachers avoided by the use of wall-maps of the continents having printed in the corner a map of England to the same scale to serve as a key. It should not be difficult for teachers to prevent their pupils from obtaining an erroneous sense of proportion.

A DISEASE resembling "farcy," the cutaneous form of glanders, has been found to be prevalent in the Philippines. It is, however, not glanders, but is due to a blastomycetic parasite which can be detected in the lesions, and may be isolated and cultivated from these, though with some difficulty.

THE Punjab Government has been compelled temporarily to suspend its scheme for extensive inoculation against plague. A portion of the vaccine fluid became contaminated and induced tetanus in a small number of persons who were inoculated with it. During the month of October, no fewer than 120,000 people were voluntarily inoculated, and it had been intended to supply 70,000 doses of the vaccine fluid per diem had not this unfortunate mishap occurred.

SIR WILLIAM MACGREGOR, in an address delivered to the students of medicine of Glasgow University, dealt especially with the prophylaxis of malaria. As the outcome of his great experience, he recommended the preventive use of quinine in doses amounting to at least 15 grains a week. He stated that in Lagos the radical method of Ross for the extermination of mosquitos is being pursued by filling in the swamps with sandy soil. The large pools which cannot be drained at present have crude petroleum put on the surface periodically. Empty tins and similar rubbish are removed, and receptacles for drinking water are kept carefully covered. Native boys are now being employed as mosquito catchers, and should be upon the fixed establishment of every European resident in such a place as Lagos.

SIR CHARLES TODD has supplied the following notes on the rainfall during the past winter (April to September) in South Australia:—As compared with the average at thirty-seven selected stations distributed over the colony, the six months' fall is, without exception, far below the average amount. It is, in fact, one of the driest years ever experienced—so far as all the northern areas are concerned it is the driest—and the same applies to many parts of the south. At twenty-four out of the thirty-seven stations, the winter of 1902 is the driest on record, whilst at eight others only one other year was drier. At Adelaide, where the records go back to 1839, during the six months April to September, 1902, we have registered only 9·49 in., or 4·64 in. under the general average; in 1891, however, we only had 7·62 in. in the same time; in 1869, 8·73 in., and in 1876, 9·24 in., whilst in 1886 we recorded 9·43, about the same as in 1902, so that as regards the city that year is not a record.

MANY theories have been put forward to account for the so-called "black and white dot phenomenon" visible on diatom valves under high powers of the microscope. A discussion of several of these theories is given by Mr. Julius Rheinberg in the *Journal* of the Quekett Microscopical Club for November. After discarding the hypothesis of spherical aberration of the object on the ground that it does not fully account for the variations observed, Mr. Rheinberg gives reasons for his opinion that the effects are due to crossing of cones of light and darkness arising from total reflection beyond the critical angle between the mounting medium and the diatom. If this hypothesis is accepted, the dots on the diatom must be regarded as perforations the depths of which are greater than their breadth; this appears to be Mr. Rheinberg's view. Lastly, a diagram of the critical angles of different media relative to diatom silex and of the amounts of light totally reflected agrees fairly well with observation.

MESSRS. ELSTER AND GEITEL, in a recent number of the *Physikalische Zeitschrift*, describe an improvement in Exner's electroscope rendering the reading of the deflections more accurate. To one of the glass sides of the instrument a mirror

is attached which reflects a scale fixed on the outside of the case. The positions of mirror and scale are such that the image of the scale when seen through an observing lens is in the same plane as the edges of the electroscope leaves. Parallax is thus avoided, and the deflection of the leaves can be read with great accuracy. In the same issue, these authors describe a convenient form of portable dry pile, giving a pressure of 2000 volts, for use in experiments on the radio-activity of the atmosphere. The pile is made up of gold and silver plates built up in columns of 200 pairs fitted on ebonite rods, thirty sets being connected in series inside a metal case. The pile gives no current, but can maintain the potential of a conductor at – 2000 volts; it is said to keep in good order for several years if proper precautions are taken.

THE South African corals of the genus Flabellum receive attention at the hands of Mr. J. S. Gardiner in a recent issue of "Marine Investigations in South Africa" (vol. ii.). The author pays special attention to the anatomy and development of these organisms, and emphasises the importance of studying the polyp as well as the corallum if we hope to gain any real idea of their true relationships.

AN additional note by Dr. Forsyth Major on *Ocapia liebrechtsi* appears in *La Belgique Coloniale* for November 30. The author figures both the male and the female skulls, the latter of which is hornless. It is suggested, however, that in some instances female okapis may carry small horns. In conclusion, it is pointed out that as the okapis of the present day are natives of a continent where zebras and antelopes abound, so their extinct forerunners, the Palæotragi of the Pliocene, were associated in southern Europe and Asia with troops of hipparions and antelopes allied to modern Ethiopian types.

WE have received from the Smithsonian Institution three papers from the *Proceedings* of the U.S. Museum. The first, by Mr. C. B. Wilson, deals with North American parasitic copepod crustaceans of the family Argulidæ. It is the first of a series dealing with the large collection of this very remarkable group contained in the Museum, and, in addition to the description of these, will contain a bibliography of the entire assemblage. It is mentioned that the typical European *Argulus foliaceus* is the only member of the group which has hitherto been fully described. In the second paper, Miss M. Rathbun treats of Japanese stalk-eyed crustaceans, describing as new one hermit-crab and nine shrimps. In the third, Messrs. Jordan and Fowler continue their review of the fishes of Japan, treating in this instance of the berychoid group.

WE have received from the publisher (Herr G. Fischer, of Jena) a copy of the second, and popular, edition of Dr. C. Chun's "Aus den Tiefen des Weltmeeres," the original edition of which was reviewed in NATURE of March 6, 1902 (vol. lxv. p. 409). The mere fact that a second edition has been found advisable affords sufficient evidence that the work is deemed a success by the public. The present issue is, however, by no means a simple replica of its predecessor. No less than eighty-two additional illustrations have been introduced into the text, while some of the original illustrations have been replaced by better ones. Moreover, the text itself has been expanded by the introduction of additional chapters dealing with the deep-sea fauna, especial attention being devoted to the description of the eyes and light-organs of abyssal animals. The new illustrations include many of tropical landscapes and others of ethnographical subjects, while views of icebergs and of the desolate scenery of Kerguelen Island are also notable additions. The present enlarged edition forms an exceedingly handsome and attractive volume, which cannot fail to interest all lovers of travel and natural history.

THE U.S. Department of Agriculture has recently issued three pamphlets dealing with the protection of the fauna of the country and the traffic in game, skins, &c. The first of the three is an enlarged and revised edition of Dr. T. S. Palmer's summary of the legislation for the protection of birds other than those classed as game. The second is a digest of the game laws for 1902, by Messrs. Palmer and Olds, giving full information with regard to close-seasons, shipment, sale and licenses. In the third and shortest, the Secretary of the Department summarises the regulations connected with the trade in birds and game between the different States of the Union. It is satisfactory to learn that the regulations for the protection of birds of which the plumage is used for ladies' dress, &c., are now extremely stringent. "Under these statutes, birds which are in demand for millinery purposes are protected throughout the year, and sale and possession, as well as killing, are prohibited. It should be remembered that the principal centres for millinery supplies are nearly all located in States which have such laws, and the purchase of native song-birds, as well as of herons, pelicans, gulls, terns, grebes or other plume-birds, should be avoided."

IN the early days of the Hudson Bay Company, a large number of skins of birds and mammals were sent from the Kewatin territory to naturalists in Europe for description, and upon the evidence of these specimens numerous species were named. Of late years, but little attention has been paid to the natural history of this semi-Arctic tract, while most other parts of North America have been ransacked for zoological specimens. And as some of the Hudson Bay species were founded on indifferent specimens, while of others the types have either been lost or are now in too bad condition for comparison, great difficulty has been experienced in correlating the fauna of the area with that of the adjacent territories, especially Alaska. To remedy this unsatisfactory state of affairs, an expedition to collect specimens was dispatched some time ago by the U. S. Biological Survey, under the charge of Mr. E. A. Preble. The results of this expedition are now published as No. 22 of the *North American Fauna*. In this fasciculus, Mr. Preble gives a full series of notes on the mammals and birds of the area, illustrated by reproductions of a number of photographs of the scenery. Of mammals, two species and four races are described as new. Perhaps the most interesting of these is the barren-ground vole (*Microtus aphorodemus*), which is described as nearly allied to *M. drummondi*, but of larger size, with a stouter skull.

THE general report on the operations of the Survey of India during 1900–1901, prepared under the direction of the Surveyor-General in India, Col. St. G. C. Gore, has now been published. Parties were employed during the year in the determination of astronomical latitudes in the Karachi longitudinal series and also on experimental work connected with the Jäderin base line apparatus. Preparations for the commencement of the magnetic survey continued during the year, and it has been arranged to establish base stations at Bombay, Kodaikanal, Dehra Dun, Calcutta and Rangoon, at which places magnetic observatories are to be built and self-recording instruments installed. The recent introduction of electric tramways in Calcutta, and their impending construction in Bombay, have rendered it necessary to arrange for the construction of new observatories at some distance from the two cities. Four parties of observers were engaged on topographical operations in Burma, one on the Lushai Hills of Assam and one in the Kangra and Simla districts. Cadastral survey operations were conducted in Bengal, the United Provinces and in Burma. Forest surveys were carried out in Madras, Bombay, Burma, Bengal, the Central Provinces and the Punjab. The report is much more concise than in previous years, owing, doubtless, to the instructions for curtailment issued in 1899.

THE "*Knowledge* Diary and Scientific Handbook for 1903," issued from *Knowledge* office, is a compendium of scientific dates, facts and data which will be found useful to students in many departments of scientific work. In addition to a general astronomical ephemeris and a calendar of events of scientific interest for each month, the book contains six charts showing the movements of twelve of the principal planets during 1903, and twelve small charts which show the appearance of the heavens during each month. There are also many useful tables and several short articles, on practical work with the spectroscope, the observation of variable stars, systematic botany and other subjects.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JANUARY:—

Jan. 2. 4h. 37m. Transit (egress) of Jupiter's Satellite IV. (Callisto).
2–3. Epoch of Quadrantid meteoric shower (radiant 230° + 52°).
6. 4h. 33m. Transit (ingress) of Jupiter's Satellite III. (Ganymede).
10. 8h. 41m. Minimum of Algol (β Persei).
12. 19h. 20m. to 19h. 37m. Moon occults λ Geminorum (mag. 3·6).
13. 5h. 30m. Minimum of Algol (β Persei).
14. 8h. 14m. to 9h. 8m. Moon occults α Cancri (mag. 4·3).
15. Illuminated portion of the disc of Venus = 0·982, of Mars = 0·910.
17. 12h. Mercury at greatest elongation, 18° 45′ East.
20. 21h. Saturn in conjunction with the sun.
30. 10h. Venus in conjunction with Jupiter. Venus, 0° 44′ South.
30. 10h. 22m. Minimum of Algol (β Persei).

MAGNETIC STORMS AND SUN SPOTS.—In an article communicated to No. 4, vol. xvi. of the *Astrophysical Journal*, Father Cortie, S.J., discusses the probable connection between terrestrial magnetic disturbances and solar activity.

Instead of dealing with mean values over an extensive period, he has compared the times of occurrence of specific isolated phenomena which have occurred during the three years 1899–1901, inclusive, and from this comparison has arrived at the conclusion that the relation is certainly not simply one of cause and effect, but rather the relation of two effects springing from a common cause.

For example, in support of this conclusion, the writer analyses the occurrences of the first six months of the past year as follows. The only spot of any size to cross the sun's disc during this period was the one observed between March 5 and 13, yet this was unaccompanied by any striking magnetic disturbance. From March 13 to May 19, the visible disc was completely free from spots, and the faculæ observed were faint and unimportant, yet a comparatively vigorous magnetic disturbance took place on April 10.

Father Cortie concludes from his detailed analysis of the last sun-spot minimum that "It may be possible that sun spots are one of the instrumental causes of magnetic storms, though not the only one, but it is more likely that the two phenomena are correlated as two connected, though sometimes independent, effects of a common cause."

OBSERVATIONS OF THE PERSEIDS, AUGUST 10 AND 11, 1902.—In No. 100 of *Popular Astronomy*, Mr. Charles P. Olivier gives the results of the observations of this shower which were made at the Leander McCormick Observatory of the University of Virginia.

On August 10, during a watch which lasted from 9h. 26m. to 16h. 8m., 44 Perseids and 28 other meteors were seen, whilst on August 11 (13h. 38m. to 16h. 8m.) 76 Perseids and 26 other meteors were recorded. The maximum display occurred during the period 13h. 59m. to 14h. 59m. on August 11, 30 Perseids and 11 other meteors being recorded during that hour.

The colour of the brighter Perseids was generally orange, and the radiant points for the two dates were $\alpha = 39°·5$, $\delta = +56°·7$, and $\alpha = 46°·8$, $\delta = +56°·7$ respectively. The latter radiant was very accurately determined from an apparently stationary meteor which appeared directly over the sixth-magnitude star D.M. + 56°·798. The paths of about one-half of the meteors observed were plotted on two charts, reproductions of which accompany Mr. Olivier's article.

THE MOSCOW OBSERVATORY.—Vol. iv. of the second series of the "Annales de l'Observatoire Astronomique de Moscou," published under the editorship of Prof. W. Ceraski, gives all the details and results of the observations made at that observatory since the last similar publication was issued.

During this interval, important work has been done in refurnishing the observatory and providing it with new instruments, in order that it may pursue its researches on modern lines. A new Henry-Repsold refractor, having two fifteen-inch objectives, has been added to the equipment of the observatory, and one of smaller dimensions is now in course of construction. The meridian circle, which has been in use since 1855, is at present being reconstructed to suit modern requirements.

The results published include the following:—Meridian circle observations, by M. B. Modestow; calculations of occultations by the moon, observations of the Leonid showers of 1897–8–9, and observations of Mars (illustrated by drawings) during 1896 and 1897, by M. S. Blakjo; observations of occultations, by MM. Sternberg, Modestow and Blakjo; and a photometric study (illustrated by two charts) of Coma Berenices, together with a description of the useful work performed with a binocular of 15 mm. aperture, by M. Ceraski.

ELECTROCHEMICAL NOTES.

THE literature of electrochemistry and electrometallurgy is rapidly increasing in volume and importance, and busy people find an increasing difficulty in keeping themselves well informed as regards the more recent developments in these new branches of science and industry. The value of periodic subject-indexes of current literature on this subject is therefore very great, and all interested in these new sciences will hail with pleasure the appearance of a monthly sheet entitled *Elektrochemische Technik*, which contains an alphabetical subject-index of all recent articles dealing with applied electrochemistry, electrometallurgy and electrotyping.

This sheet is edited and published by Dr. F. Peters, of Berlin, and the first issue is dated October, 1902. It contains references to 107 recent articles on the subjects covered by the index, and French, German, English and American papers and journals have been searched in compiling this index. In some cases, short abstracts have been given of the articles indexed.

Our issue of May 22 contained a note upon the electric resistance furnaces patented and manufactured by Heraeus, of Hanau, Germany, and the use of such furnaces for melting-point determinations. These furnaces have latterly been reduced in cost and improved in efficiency by the substitution of platinum foil only 0·007 mm. in thickness for the wire originally used, and a recent issue of the *Zeits. f. Elektrochemie* contains some notes by Dr. Haagn—the chemist to the Hanau firm, upon the use of the tube form of the improved furnace for laboratory determinations.

The most important of these for the chemist is the application of the Heraeus furnace to organic elementary analysis, and, according to Dr. Haagn, this application has been attended with success. We suppose that, when used for this purpose, the platinum spiral encircling the glass combustion tube is cut up into several sections, each with its own current connections, so that successive portions of the tube can be heated as desired. The great advantage of such a furnace, from the chemist's point of view, will be the reduction of the heat losses by radiation and by the escaping gases, since these in the usual form of gas-combustion furnace are very great, and in summer time render organic analysis a most trying and tedious operation. Other proposed applications of the Heraeus tube furnaces are for the direct estimation of carbon in steels, and for the determination of ash in coal and coke. The maximum temperature attainable with these furnaces is 1700° C., and this limit is due to the inability to produce tubes, which will retain their form at this or higher temperatures.

The use of the electric current for heating glass furnaces does not seem a very promising application of electric power to those acquainted with the high degree of efficiency obtained in the modern regenerative gas furnace now generally employed in the glass-making industry. According to a recent issue of the *Zeit-*

schrift für Elektrochemie, however, this method of heating glass furnaces has not only been the subject of practical experiments in Germany, but two glass works are now in operation, working upon this principle. Two Cologne engineers, MM. Becker and Völker, are the patentees of the more valuable and practical electric furnaces of this type, and after numerous laboratory experiments they have been able to achieve the realisation of their ideas upon an industrial scale. The first "Electric Glass Factory" was built at Plettenberg on the Lenne, where a power station of 2000 E.H.P. was available for the supply of the requisite electric energy. The results first obtained here were not very satisfactory from the economic point of view, but improvements were introduced in the process which are considered to render it a commercial success, where cheap power is available. A new company has therefore been floated, the "Aktiengesellschaft f. Elektrokeramic," and a second electric glass works has been built at Deutsch-Matrei, where electric power can be obtained at a cost of 5 pfg. per E.H.P. hour at the terminals of the furnaces. This works was to commence manufacturing operations in the summer of this year, and further details of the results obtained will be awaited with interest.

Messrs. Foerster and Müller, who have devoted much time to the elucidation of the chemistry of the electrolytic chlorate cell, contribute to the *Zeitschrift f. Elektrochemie* of August 28 and September 4 details of an extended laboratory investigation relating to the changes which occur when hypochlorite solutions are electrolysed under various conditions. Sodium hydrate, sodium hypochlorite and sodium chloride solutions were used as electrolytes in their experiments, and the results show that chlorate was formed at the anode both by primary and secondary reactions under the conditions obtaining during their tests. The primary formation of chlorate is represented by the following equation:—

$$ClO' + 2O = ClO_3.$$

This reaction, however, demands the presence of ClO' ions with anodic free oxygen and an E.M.F. at the anode above 1·1 volts. It occurs under normal conditions only to a slight extent. Secondary chlorate formation occurs at the anode, not only in solutions containing free hypochlorous acid, but also in neutral and alkaline solutions, and may be represented by the following equation:—

$$6ClO + 3H_2O = 2HClO_3 + 4HCl + 3O.$$

The formation of chlorate by this secondary reaction is, however, most active when the conditions admit of the existence of free hypochlorous acid in the electrolyte, *i.e.* when the electrolyte is maintained in an acid condition during the electrolysis. In this connection, it is interesting to note that a recent French patent in the name of Lederlin, relates to an improvement in the usual electrolytic chlorate procedure, the improvement being the continuous addition of dilute hydrochloric acid to the electrolyte in the cell.

The use of ozonised air for the purification of drinking water is again attracting considerable attention. Some years ago, experimental trials were carried out at Paris and other places with processes of this character, but the trials appear to have been unsuccessful (probably on economic grounds), and for two or three years little has been heard of ozone in connection with the water supply of large towns. During the present year, the East London Water Company has, however, been carrying out trials at Lea Bridge with an ozone process of purification, and according to one of our electrical contemporaries, these trials have been fairly successful. Prof. van 't Hoff also gave details at this year's meeting of the German Electrochemical Society of experimental trials recently made with the Vosmaer-Lebret process in Holland, and his paper is fully reported in a recent issue of the *Zeitschrift f. Elektrochemie.* The Vosmaer-Lebret form of ozoniser differs from most of those previously invented in the absence of glass as a dielectric. The silent discharges which produce the ozone in the air passing through the apparatus take place between the walls of the metallic tubes which form its essential feature. An E.M.F. of 10,000 volts with one pole earthed is used, and no artificial cooling is employed. The chemical and bacteriological examination of the water before and after treatment with the ozonised air showed that the reduction in organic matter and in the number of colonies was equal to the best yet obtained by any other process, and Prof. van 't Hoff is of opinion that the Vosmaer-Lebret process may solve the problem of a pure-water supply for large towns and cities. Experimental trials of the process are shortly to be carried out in Rotterdam, in connection with the town water-works.

The electrolytic separation of antimony from polysulphide solutions of sodium and the metal is a difficult operation, for, owing to the separation of sulphur at the anode and its re-solution in the electrolyte, the metal deposited at the kathode has a strong tendency to enter again into solution. Izart and Thomas have recently been investigating this phenomenon, and have found that the difficulty can be overcome by using a diaphragm type of cell. Some details of their experiments are given in the *Zeits. f. Elektrochemie* of September 11. The solution of polysulphide is placed in the kathode compartment, and a solution of sodium hydrate is used in the anode compartment of the cell. The conductivity of the electrolyte can be increased by the addition of ammonium salts. On passing an electric current through such a cell, sulphur separates at the anode, but dissolves in the sodium hydrate solution with liberation of oxygen. At the kathode, antimony is deposited, and there would appear to be no limit to the thickness of the deposit which can be obtained under these conditions. The process is about to be tried upon an industrial scale at Cassagnac, in France, and the results obtained will be awaited with interest. Up to the present time, the only electrolytic process for the separation of antimony which has been worked upon a large scale is that of Siemens and Halske, but no details of the plant at Banya, in Hungary, have been published, and it is possible that the results have been less satisfactory than the patentees hoped.

A NEW JOURNAL FOR GENERAL PHYSIOLOGY.[1]

THE multiplication of journals devoted to particular aspects of the various branches of a science, although indicating the vigorous growth of the last decade, is not without its disadvantages; it tends to accentuate those subdivisions of the subject which specialisation must of necessity bring about. In this respect it is refreshing to realise that the particular periodical now under review aims rather at the consolidation than at the further separation of the different aspects of physiological knowledge. In this and in other respects it is a new departure and as such merits special recognition. This will be apparent to anyone who reads the excellent introduction with which the editor, Prof. Verworn, has prefaced the first number of the new venture and which, apart from its delightful literary style, is well worth perusal since it is more comprehensive than the majority of such utterances; it forms, indeed, in itself a noteworthy and suggestive contribution to contemporary physiological literature. Of the many different points which are dealt with in this editorial, only those can be referred to here which have a direct bearing upon the scope and conduct of the *Zeitschrift für allgemeine Physiologie.* The phrase "General Physiology" has been made familiar through Prof. Verworn's masterly treatise upon the subject, but as this very treatise appears to have given rise to some misconceptions as to the meaning of the terms, the editor now defines the position with more precision. General physiology is regarded by Prof. Verworn to be the science which deals with the objective phenomena of living things in so far as they are common to all or to large groups of organisms. It is noteworthy that the qualification indicated by the word "objective" has been introduced; the reason for this introduction appears to be the desire of the editor to make it clear that in his opinion physical and chemical changes are the only data which can be properly considered to constitute the subject-matter of physiology. His affirmation of this view is particularly salutary at the present time owing to the confusion which exists as to the relation of physiology to psychology, and the modern tendency to blur our sharpness of view in regard to the former subject by reviving the vitalistic views of the past. Prof. Verworn regards with disfavour the intrusion of such idealistic conceptions as have been made familiar by the exponents of "neovitalism," and accordingly he limits the subject-matter of general physiology. He also advocates a more exact phraseology in connection with physiological processes which have been hitherto described by a terminology belonging to psychology. The use of such terms is undoubtedly

[1] *Zeitschrift für allgemeine Physiologie.* Herausgegeben von Dr. Max Verworn. Erster Band, Erstes Heft. Pp. 128 + 28. (Jena: Gustav Fischer, 1902.) Preis Mk. 24.

extremely misleading; it is difficult, for instance, to dissociate those physiological processes which are generally described as "voluntary" from having a physiological connection with "volition," and yet with volition as such physiology itself can have no dealings. In the opinion of the writer of the present review, Prof. Verworn is to be congratulated upon the firm attitude which he has taken and upon his timely attempt to demarcate the scientific frontier of his subject.

In the editorial preface reference is also made to a misconception which appears to be rather widespread, and is fundamental as regards clear definition of the subject; this is the tendency to regard general physiology as identical with what has been called comparative physiology. The latter phrase is undoubtedly a wholesome protest against the restriction as to experimental material which pervades a large section of physiological work, and which causes generalisations to be drawn from phenomena observed only in a few vertebrates—the frog, the rabbit, cat, dog and monkey. But comparative physiology as the appropriate *vis-à-vis* for the extensive science of comparative anatomy cannot at present be said to exist at all; on the other hand, there is a considerable and rapidly accumulating mass of material for general physiology in the sense in which this phrase is used by Prof. Verworn. It is true that both studies postulate investigations carried out upon an extensive range of living material; there is, however, a very real distinction between them related to the end for which the study is undertaken. If this is directed so as to ascertain the phenomena exhibited by a particular animal as such, then it fitly forms part of comparative physiology; but if it is undertaken with the object of throwing light upon analogous phenomena existing throughout widespread groups of organisms, then it can be more appropriately described as pertaining to general physiology. In this latter case the object of study is selected because it exhibits some particular physiological process in an especially striking way or under especially modified conditions. The distinction will no doubt break down as our knowledge widens and a real comparative physiology comes into being, but at present it appears to be both sound and useful. In illustration of such practical utility the writer of this article draws attention to investigations upon the phenomena exhibited by the electrical organs of fishes; these have been undertaken by physiologists in order to throw light upon the electrical changes present in such excitable tissues as muscles, nerves, &c.; it is a mere incident that they also contribute towards our knowledge of the life-history of particular forms of fish. In this connection it is desirable to explain that the editor is particularly careful to guard against giving the impression that he attaches particular value to the study of the simplest forms of life; these are extremely suitable objects of study for particular purposes but he rightly ridicules the notion of there being any special virtue in a "Protistenphysiologie."

It will be clear from the above review that a very wide scope is given to the possible subject-matter of the new journal; it includes a wealth of material if only in investigations upon all the excitable tissues both animal and vegetable. The editor's hope is to bring together, by means of the *Zeitschrift*, widely scattered researches upon most diverse objects, which will, however, all be linked through their authors' aims and points of view; the whole assemblage will thus have a direct bearing in regard to those large problems of the existence of which every physiologist is aware.

In order to encourage the advance of physiology along these lines, Prof. Verworn announces his intention of giving the new journal an international character, partly by publishing at the end of each number reviews of such researches appearing in various existing periodicals as come within the scope of the subject, but mainly by undertaking to print communications in any one of the languages made official at the Physiological Congress held last year in Turin. There are at present very few journals in which physiological communications, whether German, French, English or Italian, can appear; a physiological *Zeitschrift* of this cosmopolitan character will prove to be a real boon, and will, if successful, bring into touch workers of different nationalities in a way which must be most beneficial for the advance of their science.

Space will not permit any extended reference to the researches contained in the first number of the new journal; it may, however, be said that as regards importance and varied interest they are excellent, and that Prof. Verworn is to be congratulated upon the subject-matter of his first volume. The communications include the following original publications:—"Zur Kenntnis der Narkose," Hans Winterstein; "Neue Versuche zur Physiologie der Befruchtung," E. von Dungern; "Ueber die Reaktion des Blutserums der Wirbeltiere und die Reaktion der lebendigen Substanz im allgemeinen," H. Friedenthal; "Inanitionserscheinungen der Zelle," H. Wallengren.

There is, further, an article by Prof. Boruttau upon the older and the more modern conceptions as to the causation of nerve conduction, and reviews of various contributions to contemporary physiological and biological literature by a number of competent reviewers. The journal is well printed, and such plates as are present in this first volume are quite satisfactory. It is to be hoped that English contributions to general physiology may appear in some of the succeeding numbers; in the meantime, Prof. Verworn has the hearty good wishes of many English physiologists for the success of his undertaking. F. G.

INTERNATIONAL CONFERENCE ON WEATHER-SHOOTING.

If anyone wishes to learn the history of the subject of the effect of gun firing on weather, he cannot do better than consult a most interesting and complete history, which has recently appeared as a publication of the Central Anstalt for Meteorology and Earth's Magnetism (year 1902, vol. xxxix., Vienna). The above-mentioned history is only one of several valuable articles contributed to this volume, all of which are connected with the same subject. In fact, the publication is an account of the international conference for experts on weather-shooting which took place in July last at Graz. It may be news to many people to learn that already three international and one Italian congresses have been held, and that anyone who was interested in the subject could have attended.

The congress in question was summoned to give, if possible, definite answers to two definite questions, namely, (1) Is weather-shooting effective or not? (2) If no final judgment can be given, what should be done in future and how should one proceed? In order to prepare those interested and about to attend the conference, three monographs were published and distributed a fortnight beforehand, bringing together the whole history of the subject up to that time; the methods, apparatus and arrangements of modern weather-shooting; and lastly, the criteria for judging the effect of weather-shooting and the application of the same to the numerous "effects" and "non-effects" as reported in previous congresses and publications. Each of these are printed in the present volume and are valuable contributions to the subject.

It would take too long to enter deeply into the details of the numerous meetings and discussions at the conference itself. It is of interest to state, however, that the distinguished director of the Vienna Central Anstalt of Meteorology and Earth's Magnetism, Herr Hofrath Prof. Dr. Pernter, was general reporter to the congress, and that at the end of the volume he sums up the conclusions of the conference. The first result, as he states, was that the effect of weather-shooting, based on expert evidence, appears not only—as the overwhelming majority of the opinions of experts showed—as doubtful, but as most doubtful and, indeed, improbable when all circumstances and different weights of opinions are considered.

The second main result, restricting ourselves only to two, was that the firing should not as yet be given up, but continued until it be proved that it has not the desired effect. It may be mentioned in conclusion that this publication is a model of what such a report should be, and those who have taken part in it are to be congratulated on the successful result of their labours.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—A statement of the needs of the University has been circulated by the Vice-Chancellor among members of congregation. Applied mechanics is one of the subjects for which an additional professorship is asked. Better endowment is asked for the professorship of human anatomy, the readership in pathology, the Sibthorpian professorship of rural economy (now suspended), the chairs of geology, zoology, physics and experimental philosophy, and the curatorship of the Pitt-Rivers

Museum. A large extension of the system of readerships and lectureships is asked for in natural science, archæology and other subjects. The necessity of instituting and maintaining a laboratory for experimental research in the field of psychology is urged by several professors. The urgent needs of the University Museum, the Botanic Garden, the University Observatory and other departments of science at the present time involve a capital expenditure of about 30,000*l*. and an annual expenditure of 3050*l*.

CAMBRIDGE.—Mr. L. Doncaster and Mr. V. J. Woolley, of King's College, have been awarded Walsingham medals for their researches in biology. Mr. Doncaster wrote on hybridisation, Mr. Woolley on the effect upon a nerve of strong interrupted induced currents.

Twenty-three entrance scholarships and exhibitions in natural science have been awarded at the recent examinations held by ten colleges. For classics fifty-one awards were made, for mathematics thirty-seven, and for modern languages six.

DR. CHARLES PORTER, of the Public Health Hospital, Leith, has been appointed demonstrator in bacteriology at University College, Sheffield.

DR. G. S. PARKIN summarises in the *Times* the results of inquiry made at Oxford on behalf of the trustees of the Rhodes scholarship scheme to ascertain the conditions on which scholars will be admitted to the University and also the willingness of the individual colleges to receive the men selected. Almost all the colleges have already expressed their willingness to receive a certain number of the scholars annually. The *minimum* standard of admission to be kept in view by the trustees in making their selections is the ability to pass Responsions. Dr. Parkin adds:—"As much weighty evidence has been placed before the trustees to show that in parts of the United States, and in many of the colonies, it was felt that the bequest would be made more useful and effective if scholars were accepted for post-graduate and research work, as well as for merely under-graduate standing, the colleges were asked to state their preference in this particular. The replies were varied—some colleges inclining distinctly towards men prepared for advanced study, if within moderate age limits—while some are ready to take in scholars of both classes."

SCIENTIFIC SERIAL.

Journal of Botany, December.—The article on a new Senecio hybrid, by Mr. Burbidge and Mr. Colgan, refers to a form found at Sorrento, Ireland, which is intermediate in character between the common ragwort, *Senecio Jacobaea*, and an introduced species, *Senecio cineraria*. Besides the illustrations, which do not furnish very definite proof, the authors bring forward more convincing evidence in favour of their view.—The notes published by Mr. Spencer Moore refer to *Salvia Russellii*, two species of Barleria and a recently founded species of Amphoranthus.—Mr. C. E. Salmon records the finding of *Althaea hirsuta* near Reigate and discusses the possibility of the plant being a native or an alien.—Mr. Wheldon and Mr. A. Wilson give the localities of some mosses and hepatics which have been discovered in west Lancashire since their previous list, published in 1901.—A list of Shropshire Sphagna is compiled by Mr. W. P. Hamilton.—The revised catalogue of British Marine Algæ, with localities, compiled by Mr. Batters, is concluded in this number.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 11, 1902.—Abnormal Changes in some Lines in the Spectrum of Lithium. By Hugh **Ramage**, B.A., St. John's College, Cambridge. Communicated by Prof. G. D. Liveing, F.R.S.

The author has found that the wave-lengths of the lines belonging to the principal and the second subordinate series in the oxyhydrogen flame spectrum of lithium agree closely with those given by Kayser and Runge for the lines in the arc spectrum, but, excepting the orange line, there are considerable differences between the lines of the first subordinate series. Beginning with the orange line and proceeding to the others in order, the differences found were 0·07, 0·70, 0·49, 0·39 and 0·28 unit, the wave-lengths of the flame lines being the greater. In view of these differences, the author examined the arc spectrum in an arc struck in air and in another enclosed in a magnesia brick; the spectra of different parts of the outer flame and of the inner core of the arc were studied. He also examined the spark spectra with and without a Leyden jar in the secondary circuit. The conclusions are that the lines in the principal series appear to broaden and reverse normally. The lines in the second subordinate series do not reverse, but they broaden towards the less refrangible end of the spectrum and become diffuse on that side. The first line in the first subordinate series, λ 6103·84, broadens and reverses almost normally. The other lines in that series broaden more rapidly on the more refrangible side than on the other. The inner core of intense arcs, and the parts near the negative poles of weak arcs and sparks, give a broad reversed line with its centre about λ 4602·4, whilst the part near the positive poles in weak arcs, and the flame of the arc, give a sharp bright line, λ 4603·07, coincident with the lines in the spectra of the oxyhydrogen flame and uncondensed spark. The wave-lengths hitherto recorded for these diffuse lines would appear to be those of abnormal lines; the true lines are the sharp bright ones which occur, without complication, in the spectrum of lithium in the oxyhydrogen flame.

Entomological Society, December 3, 1902.—Canon Fowler, president, in the chair.—Mr. H. W. **Andrews** exhibited a male specimen of *Therioplectes lucidus*, from Chattenden, July, 1902. Colonel Yerbury took several females of this species at Nethy Bridge, N.B., in 1900, but there appears to be no record of the capture of the male. He also exhibited a male *Platychirus sticticus* and a female *Microdon devius* from Eltham and Shoreham (Kent) respectively; and three small dark examples of *Syrphus balteatus*, taken near Brockenhurst, where the form was not uncommon, in October, 1902.—Mr. M. **Burr** exhibited two species of Phyllium from Ceylon, sent by Mr. Green, *P. bioculatum*, Gray (= *erurifolium* Hann., and *scythe* Gray), which produces the flanged ova and is the commoner of the two, and *P. athanysus*, Westw., a scarce species with the less ornate ovum.—Mr. A. J. **Chitty** exhibited a box of insects, taken, between September 22 and October 7 last, from a decayed fence chiefly constructed of birch. The exhibit comprised about a hundred species, of which seventy-nine or eighty were Coleoptera. Four species of beetles mimicked the surroundings of lichen-covered bark, and one, *Acalles tribatus*, resembled buds.—Mr. R. **Adkin** exhibited a hybrid *Selenia bilunaria* × *S. tetralunaria*, together with spring and summer examples of both species for comparison. The hybrid presented some of the markings of each of its parents, the crescentic blotch at the apex of the fore-wings and the band on the hind-wings closely following *tetralunaria*, but no trace of the dark spot usually so distinct on each of the wings of that species, especially in the summer emergence, was visible, while the "second line" of the fore-wings closely followed *bilunaria*. In colour it more nearly resembled that of the summer brood of *tetralunaria*.

Geological Society, December 3, 1902.—Prof. C. Lapworth, F.R.S., president, in the chair.—On some well-sections in Suffolk, by Mr. William **Whitaker**, F.R.S. Notes of thirty-one new wells have accumulated since 1895, some of them giving results which could not have been expected. A trial-boring for the Woodbridge Waterworks Company gave a depth of 133¾ feet down to Eocene beds, and a thickness of Crag about double of any before observed in the neighbourhood. The author is not satisfied with any of the explanations which have been suggested. Two borings at Lowestoft show that Crag extends to a depth of 240 feet in one case and more than 200 feet in another, confirming estimates of Mr. Harmer and Mr. Clement Reid. In one of these, Chalk was reached at 475 feet. Three other wells in the neighbourhood confirm the great depth of the newer Tertiary strata. Sections are also given from the following places:—Boulge, Hitcham Street, Ipswich (corroborating the evidence for a deep channel filled with Drift given by the section at St. Peter's Quay, New Mill), Shotley, Stansfield and Brettenham Park. The last shows the greatest thickness of Drift recorded in the county, namely, 312 feet.—The cellular magnesian

limestone of Durham, by Mr. George **Abbott**. The Permian Limestone covers about $1\frac{1}{4}$ square miles near Sunderland; it alternates with beds of marl containing concretionary limestone-balls, and attains a thickness of 65 feet or so. The cellular limestones frequently contain more than 97 per cent. of calcium carbonate. Magnesium carbonate occupies the interspaces or "cells" of this limestone, and also the spaces between the balls. The patterns met with in it can be arranged into two chief classes, conveniently termed honeycomb and coralloid, each with two varieties; both classes have begun with either parallel or divergent systems of rods. The second stage is the development of nodes at regular distances on neighbouring rods, and these in the third stage, by lateral growth, become bands. Finally, in the fourth stage the interspaces become filled up. The upper beds are usually the most nearly solid. In the coralloid class, the nodes and bands are smaller and more numerous than in the honeycomb class. In both classes, tubes are frequently formed. The rods have generally grown downwards, but upward and lateral growth is common.

Anthropological Institute, December 9, 1902.—Dr. A. C. Haddon, F.R.S., in the chair.—Mr. C. **Lumholtz**, of the American Museum of Natural History, read a paper on the symbolism in art of the Huichol Indians of Mexico.—Messrs. Nelson **Annandale** and H. C. **Robinson** read a paper on some results of an expedition to the Malay Peninsula. The paper described the districts which were visited by the authors, the investigations undertaken and the material obtained. I. The *civilised tribes* are as follow:—(1) *Malays and Siamese of the district between Singora and Jambu.* Physical differences between the two are slight or absent; there is evidence of an admixture of aboriginal blood, though the aborigines are now practically extinct in the district. Two distinct physical types are to be recognised, but neither can be associated with one people or the other. Mohammedan and Buddhist customs were noted. The amusements, opium-smoking, diseases and modes of burial were described. (2) The *South Perak Malays* are distinct from the people of Patani, their standards of civilisation more occidental, but their race is non-persistent, being swamped by immigration. (3) In *Selangor* there is no long-established Malay population. (4) The *Samsams of Trang* are identical with or nearly related to the Malays of Upper Perak, but certain physical differences from the Malays of South Perak were noted, and their language, religion and weapons were described. II. The *savage tribes* are the following:—(5) *Semangs.* Their distribution, social status, physical characters and mode of life were described. (6) *Sakais.* Their distribution and relationship to Semangs were noted, and their mode of life, external relations and burial customs. (7) *Orang Laut Kappir of Trang.* Their possible relationships were discussed, with their dialect, religion and customs.

CAMBRIDGE.

Philosophical Society, November 24, 1902.—Dr. Baker, president, in the chair.—The origin of the thoroughbred horse, by Prof. **Ridgeway** (see p. 187).—Note on the resolution of compound characters by cross-breeding, by Mr. W. **Bateson**. In this note, the case of resolution of character recorded by de Vries ("Mutationstheorie," Lief. iv. p. 196) is discussed. A red Antirrhinum crossed with a white gave hybrids which on self-fertilisation gave four forms in numbers suggesting the ratio 9 : 3 : 3 : 1. These results are treated by de Vries as phenomena of "dihybridisation," but in the present communication it is pointed out that the facts so far do not preclude an apparently simpler account.—Notes on rearing the later stages of echinoid larvæ, by Mr. L. **Doncaster**. The difficulties which workers at echinoid development have met with in rearing the larvæ were pointed out, and the methods used by MacBride and others were described. At Naples in the spring and summer of 1902, it was found possible to rear larvæ of *Strongylocentrotus lividus*, *Echinus microtuberculatus* and their hybrids beyond the metamorphosis without using either a plunger or specially large jars. The larvæ were kept in four litre jars, and supplied about five times a week with fresh sea-water taken several kilometres from the coast. The larvæ usually developed healthily and metamorphosed about thirty days after the fertilisation of the eggs. Other species, such as *Sphaerechinus granularis*, however, could not be induced to develop by these means. The hybrid urchins lived for only a few days after the metamorphosis, but those of Strongylocentrotus were kept in some cases for a month, but did not change greatly during that time. The later larvæ and young urchins of the two species mentioned resembled one another very closely.—(1) On the Galois theory of differential equations; (2) On the structure of continuous groups, by the president.—Note on spontaneous ionisation in air at different temperatures and pressures, by Mr. J. **Patterson**. The object of the experiment was to find, if possible, the cause of the so-called spontaneous ionisation in air. To measure the spontaneous ionisation at different temperatures, the air was contained in an insulated iron cylinder containing about thirteen litres, and the rate of leak was measured between the walls of the vessel and an insulated electrode. This electrode was connected to one pair of quadrants of a very delicate electrometer and the rate of leak observed. The experiments showed that from the temperature of the room (20° C.) to about 500° C. the current through the gas was constant, the air in the cylinder being at atmospheric pressure throughout the investigation. To measure the ionisation at different pressures, the same cylinder and electrode were used. The joints were made air-tight with sealing-wax and the air filtered through glass wool. The results showed that down to a pressure of about $\frac{1}{3}$ atmos. the current through the gas was independent of the pressure and that for pressure below 90 mm. of mercury the ionisation was proportional to the pressure. Using the value 6×10^{-10} for e, the charge on an ion, the number of ions produced per c.c. per sec. was about 30. The results of the experiments indicate that the "spontaneous ionisation" is really due to easily absorbed radiation from the walls of the vessel.—Note on the behaviour of a potassium amalgam kathode in a vacuum tube, by Mr. T. **Lyman**.

MANCHESTER.

Literary and Philosophical Society, December 16, 1902.—Mr. Charles Bailey, president, in the chair.—Mr. Frank **Southern** and Dr. Charles H. **Lees** exhibited some Japanese magic mirrors.—Mr. R. W. **Ellison** exhibited a series of eggs of the common guillemot (*Uria troile*), showing great variety in coloration and design of markings, eggs of various shades of green, blue, yellow, brown and red being prominent.—Mr. C. E. **Stromeyer** read a paper on the graphic computation of lenses, in which he described a simple method of computing oblique rays of light which do not cross the optic axis of a lens system.—Mr. A. **Adamson** read a paper on a simple form of vernier microscope. The apparatus is specially devised to suit the elementary student in a physical laboratory who is familiar with the use of the vernier and who wishes to calibrate or determine the bore of a glass tube by measuring the length of a mercury thread within it.

PARIS.

Academy of Sciences, December 22, 1902.—M. Bouquet de la Grye in the chair.—The **president** delivered his annual address.—The prizes offered for the year 1902 were awarded as follows:—In geometry, the subject proposed for the Grand Prize was to improve in an important point the application of the theory of continuous groups to the theory of partial differential equations, the memoir crowned being that of M. Ernest Vessiot, M. Jean le Roux receiving a very honourable mention; the Bordin Prize is not awarded, M. de Tannenberg receiving an honourable mention for perfecting the theory of surfaces applicable to the paraboloid of revolution; the Francœur Prize is awarded to M. Emile Lemoine for the whole of his works on geometry, and the Poncelet Prize to M. Maurice d'Ocagne for his works on nomography. In mechanics, the Extraordinary Prize of 6000 francs is divided between M. Romazotti and M. Driencourt, M. Hartmann receiving a Montyon Prize, for his experiments on the production of the lines of slipping on the surface of elastic bodies due to their deformation, and M. Renard the Plumey Prize, for the whole of his works. In astronomy, the Pierre Guzman Prize is not awarded, the Lalande Prize falling to M. Trépied, the Valz Prize to M. Hartivig, the Damoiseau Prize to M. Gaillot, for his study of the theory of the motion of Saturn, the Janssen gold medal to M. le Comte Aymar de la Baume-Pluvinel, an encouragement and a Janssen medal being accorded to M. Jean Binot. In geography and navigation, the Binoux Prize is divided between MM. Claude, Marcel Monnier and Delpeuch. In physics, the Hébert Prize is awarded to M. C. F. Guilbert, for his work

entitled "Les générateurs d'électricité à l'Exposition de 1900." In statistics, the Montyon Prize is divided equally between M. F. Bordas, for a statistical study of the mortality in infants due to gastro-enteritis, and M. H. Duchaussoy, for a memoir on the meteorological observations of Victor and Camille Chandon de Montdidier, exceptionally honourable mentions being accorded to M. Liétard, for his work on the population of the Vosges, M. Paul Dislère, for his memoir on colonisation, and M. Peyroux, for a study of the causes of the depopulation of Elbeuf, mentions being accorded to M. R. Leroy, for a contribution to the study of alcoholism in Normandy, M. L. Mayet, for memoirs on the distribution of goitre in France and statistics of alcoholism, and to MM. Passerat and Trousseau. In chemistry, M. Rosenstiehl receives the Jecker Prize, for the whole of his works, especially those bearing on organic chemistry. In mineralogy and geology, M. de Grossouvre receives the Fontannes Prize, for his work in the field of palæontology. In physical geography, the Gay Prize is awarded to M. Berthaut, for his historical studies on the cartography of France. In botany, Mr. Roland Thaxter receives the Desmazières Prize, for his studies on the parasitic fungi of American insects, and M. Vuillemin the Montagne Prize, for his memoirs on the morphology and biology of fungi. In anatomy and zoology, the Savigny and Vaillant Prizes are not awarded, the Thore Prize falling to M. R. de Sinéty. In medicine and surgery, Montyon Prizes are accorded to M. J. Dejerine, for his memoir on the semiology of the nervous system, to M. G. H. Roger, for his work on infectious diseases, and to M. P. Ravaut, for a memoir on the cytodiagnosis of pleurisy, MM. Commenge, Comby and Guillemonat receiving mentions, and MM. E. Bodin, V. Griffon, E. Fournier, C. Guérin and Cassaët citations. The Barbier Prize is divided between M. Grimbert, for his work in chemical biology, bacteriology and hygiene, and M. Le Dentri, for a clinical statistical study of cancer of the breast. M. Ed. Imbeaux receives the arrears of the Bréant Prize, M. G. Loisel the Godard Prize, for his notes and memoirs relating to the histogenesis and physiology of the male sexual elements in birds, M. Pierre Lereboullet the Bellion Prize, for his work on cirrhosis of the liver, M. A. Clerc the Mege Prize, for a study of some soluble ferments in blood serum, and M. Triaire the Baron Larrey Prize, for his biography of D. Larrey, a very honourable mention being accorded to M. Romary, the Lallemand Prize being divided between Mlle. Pompilian and M. Hauser. In physiology, the Montyon Prize in experimental physiology is not awarded, M. Pierre Bonnier receiving the Philipeaux Prize, for memoirs on orientation and sense of altitude, M. Paul Marchal the Serres Prize, for his researches on the development of the parasitic Hymenoptera, M. J. Tissot the Pourat Prize, for a comparative study of the mechanism of respiration in mammals, and M. H. Blondel de Joigny the Martin-Damourette Prize, for his work on the pathogeny and prophylaxis of myopia. Of the General Prizes, the Lavoisier medal is awarded to M. Stanislas Cannizzaro. In accordance with the decision of the Academy to award a certain number of Berthelot medals to those obtaining prizes in the sections of chemistry and physics, MM. Rosenstiehl, Minet, Clerc, Imbeaux, Bordas, Dislère, Peyroux, Grimbert, Grignard, Fosse and Marquis, and Mme. Curie receive Berthelot medals. The Montyon Prize (unhealthy trades) is awarded to M. Claude Boucher, for a report on the methods for the mechanical manufacture of bottles, the Wilde Prize to M. Schulof, for his work on comets and shooting stars, the Tchihatchef Prize to Dr. Sven Hedin, for his scientific explorations in Central Asia, the Delalande-Guérineau Prize to M. Gonnessiat, for his work in connection with the geodetic expedition to the equator, the Jérome Ponti Prize to M. André Tournouër, for his explorations in Patagonia, the Houllevigue Prize to M. Teisserenc de Bort, for his researches on the state of the atmosphere at high altitudes, the Gegner Prize to Mme. Curie, for her work on radio-active bodies, and the Trémont Prize to M. Frémont, the Saintour Prize being divided between M. Riquier, for his work on the integration of partial differential equations, and M. Adolphe Minet, for his researches on the electrolytic production of aluminium, and the Cahours Prize between MM. Fosse, Grignard and Marquis. The prize founded by Mme. la Marquise de Laplace is given to M. Aubrun, that founded by M. Félix Rivot being divided between MM. Aubrun, Niewenglowski, Barrillon and Bénézit.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 1.

RÖNTGEN SOCIETY, at 8.30.—X-Ray Work in Private Practice: Dr. G. M. Lowe.

MONDAY, JANUARY 5.

VICTORIA INSTITUTE, at 4.30.

ROYAL GEOGRAPHICAL SOCIETY, at 4.30.—Landscapes in the Volcanic Districts of France: Dr. A. J. Herbertson.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Note on the Fluorescence of Naphthalic Anhydride: Dr. J. T. Hewitt.—The Saponification of Fats and Oils by means of Dilute Acids: Dr. J. Lewkowitsch.

WEDNESDAY, JANUARY 7.

GEOLOGICAL SOCIETY, at 8.—On the Discovery of an Ossiferous Cavern of Pliocene Age at Doveholes (Buxton), Derbyshire: Prof. W. Boyd Dawkins, F.R.S.

THURSDAY, JANUARY 8.

MATHEMATICAL SOCIETY, at 5.30.—A Method of representing Imaginary Points by Real Points in a Plane: Prof. A. Lodge.—On the Mathematical Expression of the Principle of Huygens: Dr. J. Larmor.—Generational Relations for the Abstract Group simply Isomorphic with the Linear Fractional Group in the Galois Field [2^n]: Prof. L. E. Dickson.—Series connected with the Enumeration of Partitions (second paper): Rev. F. H. Jackson.—On the Jacobian of Two Binary Quantics considered Geometrically: Prof. W. S. Burnside.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Notes of Recent Electrical Design: W. B. Esson.—Notes on the Manufacture of Large Dynamos and Alternators: E. K. Scott.

FRIDAY, JANUARY 9.

ROYAL ASTRONOMICAL SOCIETY, at 5.

GEOGRAPHICAL ASSOCIATION, at 3.30.—The Australian Commonwealth: Sir John A. Cockburn.

TUESDAY, JANUARY 13.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Electric Automobiles: H. F. Joel.

FRIDAY, JANUARY 16.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Measurement of Water: Prof. W. C. Unwin, F.R.S.

FIRE PREVENTION.

Facts on Fire Prevention. Edited by Edwin O. Sachs. 2 Vols. Vol. i., pp. xxviii + 219; vol. ii., pp. vi + 226. (London: Batsford, 1902.)

THERE is so much solid matter in these works and such an amount of detail beyond the scope of an ordinary review that at first sight it seems difficult to summarise the whole; but an effort may be made to bring out the essential points sufficiently to indicate the general purport of the important subject dealt with in the 445 pages and the numerous illustrations contained in the two volumes under notice.

The principle adopted by the British Fire Prevention Committee is to give actual results of a number of practical investigations into materials and systems of construction, without commenting on or recommending any individual material or method, leaving entirely to those interested in buildings to judge for themselves as to how far such materials or methods accord with their individual requirements or specific works.

Of this principle as here enunciated almost in the Committee's own words, entire approval may be accorded; but when they go on to add that the adoption of remedies for existing defects can only be attained by the aid of legislation, meaning, of course, additional legislation, a totally new subject comes under consideration, on which it is necessary to join issue.

A careful study of the existing building laws, at least in London, goes to show that what is wanted is not so much new legislation as the faithful, firm, honourable and scrupulous execution of the present laws.

In short, it comes to this. The laws have been carefully thought out and, though not perfect, are quite sufficiently clear to justify responsible public bodies in carrying them out with strictness; but the responsible bodies are timid, not to say cowardly or worse, and the result is that everyone who chooses to fly in the face of the legal ordinances obtains some sympathetic approval from the general public and, what is much more unfortunate, occasional specific support from certain members of the public body charged with the duty of carrying out the orders of the legislature.

One of the most extraordinary and discreditable characteristics of our time is that every public body from the highest to the lowest now seems to contain a few members whose boast it is to oppose in every possible way the known intentions of the legislature, even in the special matters which the legislature has delegated to their charge.

This may seem to be a digression from the subject, but a brief explanation may be offered.

In America, the building laws are absolutely perfect. Even the Code Napoléon, the most complete of all, and, in fact, the model of all, was not more perfect, if there can be degrees in perfection, and yet in America, with an expenditure on fire appliances unparalleled elsewhere, the losses by fire are so heavy as to bring fire-insurance companies almost to despair and outlying communities occasionally to ruin.

It is not too much to hope that the time is coming when we can look with confidence and satisfaction to the honourable and rigid execution of our existing laws—in short, to the honesty and courage of those responsible for carrying out the duties which they have undertaken.

This is a point on which it is necessary to express a disagreement from the views of the British Fire Prevention Committee.

The Committee says that the Building Act of the Metropolis requires material revision and that opportunity should be taken to restrict change of purpose in buildings from that for which they were originally constructed; but to a thoughtful and experienced reader of the existing laws, it would appear that all such subjects have been sufficiently dealt with, and that it only requires honest and straightforward action on the part of the executive to carry out the undoubted intentions of the legislature.

This seems to be the great difficulty, the only real difficulty, at the present time, but it is very serious.

Consideration for interested individuals appears to be greater than consideration for communities, and all the weaker members of public bodies seem to lean towards concessions and immunities, although their position and sworn acceptance of duty to carry out existing laws admit of no mitigation or modification.

If ever there are found men in this country, as it may be assumed there will be in time, determined to carry out faithfully and rigidly the laws under which they are embodied, a great change will be observed; until then we must wait and hope, but we do hope with confidence.

The practical methods of testing building materials and modes of construction adopted by this Committee are most complete, and the results are consequently trustworthy.

In "Facts on Fire Prevention," it is stated that for the reduction of loss by fire two remedies are to be found—one, better building construction, the other, more efficient methods of extinguishing fires—and with the latter the present work is stated "to have nothing to do on this occasion," a wise limitation on the part of those concerned, as it is highly improbable, indeed almost impossible, that they can have had experience in the difficult business of extinguishing conflagrations.

The following tests are selected from the very large number detailed in the books:—

"*A Floor of Solid Wood Beams.*
"*Object of Test.*

"To record the effect of a smouldering fire of twenty minutes' duration at a temperature not exceeding 500° F., followed by a fierce fire of one hour gradually increasing to a temperature of 2000° F., followed suddenly by the application of a stream of water for five minutes and the consequent rapid cooling.

"The area of the floor was 100 or 10 × 10 superficial feet, and it was loaded with 20lbs. to the square foot.

"*Summary of Effect.*

"The under surface of the wood beams was charred to an average depth of two inches, but beyond this no damage was done."

L

This was a very instructive test, and another making a comparison between doors of different material and construction gives some important results :—

"*A Wood Door covered with Tinned Steel Plates.*
"*An Iron-framed and Panelled Door.*
"*Object of Test.*

"To record the effect of a fierce fire of one hour gradually increasing to a temperature of 2000° F., followed suddenly by the application for five minutes of a stream of water and consequent rapid cooling.

"The door-openings were approximately 3ft. 9in. by 7ft. 3in., and the doors hung to open inwards—that is towards the fire.

"*Summary of Effect.*

"The wood door covered with tinned steel plates remained in position, but was much buckled and bulged, and the upper part gradually inclined inwards to a considerable extent, permitting the passage of flame. The first spurt of flame over the top of the door was seen after five minutes.

"The iron-framed and panelled door remained in position, but became red hot, buckled and warped considerably together with its rebated frame. The upper corner on the lock side gradually inclined inwards to a considerable extent, permitting the passage of flame. The first spurt of flame was seen after twenty minutes."

The two volumes under consideration contain the following numbers of tests, all of the same elaborate kind as the two selected for quotation, and with excellent illustrations showing the construction of the objects tested and the appearance presented after the tests :— Floors 11, ceilings 2, partitions 11, materials 1, doors 23, glazing 8, fire-curtains 3, making in all 59.

The Fire Prevention Committee intimates that

"In order to ensure the steady continuation and development of its investigations, it is absolutely necessary that it should receive every possible support from public authorities, learned societies, the professions interested, and above all from that great community of industrial firms primarily affected by fire."

It may be hoped that this kind of support will in some manner be afforded, but it has to be remembered that the kind of bodies appealed to can never be expected to move quickly and that some interference on their part would be inevitable ; so that on the whole it may be doubted whether it would have been possible for the Committee within the space of five years, which it gives as the period of its existence, to provide the large amount of information contained in these volumes, if it had been hampered with the collaboration of any external influence.

The volumes under consideration contain much valuable and trustworthy information on a subject quite unknown to the general public and only imperfectly known to many so-called experts, of whom some have taken up one branch, some another, but very few have mastered the details of all.

In conclusion, it may be stated that the volumes entitled "Facts on Fire Prevention" should prove of great assistance to all who have to deal with the preservation of life and property from fire. EMERITUS.

TWO BOOKS ON IMMERSED SHIPS.

Aërial Navigation: a Practical Handbook on the Construction of Dirigible Balloons, Aërostats, Aëroplanes and Aëromotors. By Frederick Walker, C.E. Pp. xvi + 151. (London: Crosby Lockwood and Son, 1902.) Price 7*s*. 6*d*. net.

Submarine Warfare, Past, Present and Future. By Herbert C. Fyfe. With an Introduction by Admiral the Hon. Sir Edmund Robert Fremantle, G.C.B., C.M.G., and a Chapter on the Probable Future of Submarine Boat Construction by Sir Edward J. Reed, M.P. Pp. xxviii + 332. (London: Grant Richards, 1902.) Price 7*s*. 6*d*. net.

THE problems dealt with in these two books have a certain similarity in that in each case the ship, or to use a more general term, the machine or contrivance, has to navigate wholely immersed in the medium for which it is designed, and this similarity is not disturbed by the condition that the submersible may have also to navigate on the upper surface of the sea, for the balloon, and especially the flying machine, equally has to start and to finish at the lower surface of the atmosphere.

There is also a similarity in the two books. The price of each is the same, to wit 7*s*. 6*d*. Here the similarity ends. It would be difficult to find accidentally thrown together two works which might have so much in common, but which make so violent a contrast.

The aërial book is disappointing, to say the least. A large part is taken up with descriptions and illustrations of the schemes of the hopeless crank. These are described as seriously as the few attempts which have been made by engineers and others on sounder lines, and the reader is left without guidance as to how much is worthy of sober consideration. An appearance of precision is imparted by the introduction of a large number of formulæ and of tables calculated from them the accuracy of which it does not seem necessary to examine. It is a little remarkable that with such an extended title the author should not have thought the names of Lilienthal and of Pilcher worth mentioning. The dreariness of this practical handbook is slightly relieved by some diagrams of the machine of Santos Dumont and by quite a nice frontispiece showing the rounding of the Eiffel Tower.

In his "Submarine Warfare," Mr. Fyfe has in effect collected and produced a series of essays, partly historical, partly mechanical and partly of more general interest, on the submarine from different points of view. This is not a text-book in any sense of the term, but a work which anyone of wide interests will read with pleasure. It is not necessary to begin at the beginning and read solidly through lest anything should be lost which would make subsequent chapters unintelligible. The reader may pick and choose first whichever chapter most takes his fancy. The illustrations are numerous and excellent.

There has been considerable doubt in this country whether the submarine will be found a valuable weapon in war, *i.e.* valuable to those who use it, or whether when the time comes to put it to serious trial it will be found more dangerous to the crew than to the ships which it is attacking. It is certain that until very recently this was

a very general opinion here, even though we knew that in France especially the development of the submarine and submersible was being very seriously pursued, and that the trials excited the enthusiasm of the public.

Now, however, that we know that our Government is quietly making its own experiments with submersibles built in this country, and that we have an introduction and a chapter in the book under review written by men of such repute as Sir Edmund Fremantle and Sir Edward Reed, in which the writers show that they are fully alive to the progress and to the great possibilities as well as to the present limitations of this new weapon, we can no longer affect to despise the armed and diving boat, but must at least prove, using the best skill we possess, what is possible both in the way of offence by and of defence against so terrible a weapon. Sir Edward Reed, after referring to the difference in density of the two media water and air, goes on as follows :—

"But it is in the face of this initial and enormous difficulty that the aëronauts of to-day have apparently persuaded themselves that they can successfully float their balloon-ship in mid-air and propel it, not only against the rapid tides of the air in which it floats, but also drive it at a good additional speed. When men are to be found capable of committing their fortunes, and even their lives, to navigation of this kind, it is not surprising to find that the far easier problem of navigating the seas beneath the surface has won the attention and the effort of enterprising men. They certainly have chosen, if the humbler, also the more promising and practical field of operation. I doubt not that they have likewise chosen the more fruitful field."

Passing over a long but interesting chapter on the morality of submarine warfare, we come to one on the mechanism of the submarine which perhaps more than any deals with the numerous scientific problems that arise. One of the troubles of the immersed ship which is not felt on the surface is the terrible effect of a small change in the position of the centre of gravity. For instance :—

"The Nordenfelt boats were certainly not successful in discharging torpedoes, for as a general rule they as nearly as possible stood up vertically on their tails and proceeded to plunge to the bottom stern first on these occasions."

By allowing the torpedo tube to fill with water immediately after the discharge, this difficulty is reduced, but it is almost wholly removed by the invention of Mr. Drzewiecki, who has contrived a clamp to hold a torpedo securely outside the boat, by which it can be turned in any direction from the inside and then be liberated by the pressure of the moving water. As the torpedo has a density nearly that of water, its liberation does not affect the stability of the ship. It has been tried with success at Cherbourg.

Even though the mechanical problems are perfectly solved of the different stabilities, of propulsion, of air maintenance, of torpedo discharge and of rising and of plunging, but not below the fatal depth, there remains the horrible fact that under water a ship is blind. When at the surface or awash, the bearings of the enemy may be taken from the cupola, and after plunging, the compass or the gyroscope alone remain to give the sense of direction ; but a compass is not at its best in such a position. Various optical tubes and telescopic periscopes are used to get some sort of view when the ship is not far from the surface, but to what extent successfully it is difficult to discover. At any rate, it is satisfactory to know that in this country the problem has been attacked by so able an optical engineer as Sir Howard Grubb.

One of the most disturbing chapters is that on the antidote to submarines. Information as to what has been done quietly in this country as elsewhere is, of course, difficult to obtain, but even though a charge of high explosion fired in the water may damage or destroy a submarine that is near enough, it is impossible to feel that there is any reasonably sure method of defence against this insidious weapon, always on the supposition, of course, that the mechanical and optical problems referred to are solved in even a fairly satisfactory way.

C. V. B.

WOLLEY'S COLLECTION OF BIRDS' EGGS.

Ootheca Wolleyana. An Illustrated Catalogue of the Collection of Birds' Eggs formed by the late John Wolley, jun., M.A., F.Z.S. Edited from the Original Notes by Alfred Newton. Part ii., Picariæ—Passeres. (London : R. H. Porter, 1902.)

TO European oologists, the name of John Wolley is both well known and held in great esteem, for not only was he one of our soundest and best ornithologists, especially in the field, but also was one of the first egg collectors who fully realised the extreme importance of securing the identification of the parent bird, of carefully, and if possible indelibly, marking each egg when taken, so as to avoid all risk of error, and of procuring and noting down the fullest possible information respecting each clutch, as well as of collecting a series of specimens to show all the variety of colour, size and shape to which eggs of the same species are subject. Collectors will therefore gladly welcome the present part, which completes the first volume of the "Ootheca Wolleyana."

The first part was published so far back as 1864, but the present part, completing the volume, has been retarded from various causes, though this somewhat long delay cannot be regretted when one realises, from a perusal of the work, how carefully the editor has brought the work up to date.

Wolley commenced the study of natural history at a very early age, and after occupying himself with botany, entomology and the habits of animals generally, he gradually began to pay special attention to oology, until after a trip to Spain in 1845 and a visit to Morocco, where he discovered M. Favier, who afterwards became so well known to ornithologists, he devoted himself chiefly to that branch of science. After his return to England, he several times visited Scotland in order to study birds in the field, especially the rarer species at their breeding places. In 1850, he made an excursion to the Faroes, which had never before been visited by any English naturalist, communicating an account of the ornithology to the British Association. In 1853, he began the work with which his name will always be associated, the investigation of the ornithology of Lapland, of which no

connected account had been published for nearly a century. Guided by geographical considerations, he fixed his headquarters on the banks of the great Muonio River, nearly half-way between the head of the Gulf of Bothnia and the Arctic Ocean, at a little Swedish farm opposite to the Finnish village of Muonioniska, and at once began to explore the country in every direction. These explorations he carried on personally for five summers and three winters, extending them to the Norwegian provinces of Nordland and Finmark, as well as to the western portion of Russian Lapland, not omitting the great lake Enara, which he found to be singularly destitute of bird-life. In all this work, he was greatly aided by a young lad, Ludwig Knoblock, with whom he fortunately fell in immediately on his arrival in the country, and finding him to possess a strong taste for observing natural objects, generally intelligent and, above all, truthful, he took him into his service and by training made him the valuable assistant he proved to be. To his perseverance, naturalists owe the solution, in 1856, of the mystery which had hitherto surrounded the nidification of the Waxwing (*Ampelis garrulus*), sought for as it had been by many travellers and in many countries. Wolley himself was never so fortunate as to see this bird, but the success which rewarded his exertions to obtain the eggs of many until then unknown or little known species can best be realised by those who are well acquainted with the last edition of Hewitson's work on the "Eggs of British Birds," in which so many of the rarities were figured. Wolley took copious notes respecting the various eggs obtained by him or his collectors, which have been most carefully reproduced in the present work, and will be of the greatest interest and use to both cabinet and field naturalists.

In 1858, Wolley, who for years had been carefully studying what was known of the history of the Great Auk (*Alca impennis*), undertook a voyage to Iceland, in company with Prof. Newton, for the purpose of making further investigations. It was assumed that this species was extinct, though no one knew that such was the case or how it had become so. Much information respecting its latter years were obtained, and it was ascertained that the last two living examples were procured at Eldey, on the south-west coast of Iceland, in 1844.

The year following this expedition, Wolley's health began to decline, and his death occurred in 1859 at the early age of thirty-six.

His valuable egg collection passed into the possession of Prof. Newton, who retaining in his service some of Wolley's collectors, has added considerably to it, hence many species are included in the present catalogue which were unknown to Wolley.

Amongst the additional notes from the pen of the editor may be especially noticed those on the nidification of the Nutcracker. Four coloured plates of ninety-seven specimens of eggs are given, which, though excellent reproductions of the various eggs and well illustrating the variation in shape, colour and markings, were, as stated in the introduction, executed some time ago. Four lithographic plates of landscapes also accompany the work, two of which are scenes in Lapland, the third being a view of Eldey, the last home of the Great Auk or Garefowl, and the fourth a view of the Alkenhorn in Spitsbergen.

Last, but not least, is an excellent memoir of Wolley, with a very good portrait of him and one of his head assistant, Ludwig Matthias Knoblock, the perusal of which will give infinite pleasure to many an oologist.

THE WANDERINGS OF A NATURALIST IN SOUTH AMERICA.

The Great Mountains and Forests of South America. By Paul Fountain. Pp. 298. (London: Longmans, Green and Co., 1902.) Price 10*s.* 6*d.* net.

IT was only a few months ago that we reviewed a book by the same author on "The Great Deserts and Forests of North America." We learn from the introduction to the present volume that it was originally intended to form a second part of that work, but, on the advice of the publishers, it was "amplified" to make a separate book. Unfortunately, the process of expansion does not appear to have been very happily carried out. In several cases, statements are repeated almost in the same words, and the volume is eked out by a quantity of miscellaneous matter that has little relation to the rest of the book. But the love of nature and the keen observation of animal life that procured so warm a welcome for Mr. Fountain's description of the deserts of the United States are not wanting when the scene is changed to the great forests of the south.

It was in 1884 that the author left behind him the region with which he has made us familiar and set out on his travels in the southern continent. It is a misfortune that he has allowed so long a time to elapse before giving his experiences to the world. It was inevitable that after the passage of nearly twenty years regrettable inaccuracies should find their way into his pages, and these seriously diminish the value of the book.

Taking Obydos on the Amazon as his base, he ascended the Rio Trombetas and subsequently the Rio Purus and several of its tributaries in a boat he had purchased in Pará, transferring himself to a bark canoe of his own manufacture when the water was too shallow for the larger vessel. After his return to Obydos, we lose sight of him for a time and then find him making his way through the forest of the upper Xingu valley to Diamantino in Matto Grosso, where he again passes out of view to reappear sporadically in Guiana, Ecuador, Colombia, Peru, Bolivia and Chili, and finally take leave of us at Rio de Janeiro.

The author is at his best in the description of his excursions up the smaller tributaries of the Purus in the twilight of the overarching trees. It was there, especially, that he was able to make a close acquaintance with the "jungle folk" of the Amazonian plain, of whom those who travel by only the more frequented ways know but little. His long experience as hunter and collector stood him in good stead, and the variety of the forms of life that he met with will seem marvellous to many who have passed over much of the same ground. He does not pretend, however, to scientific accuracy in the determination of species of animals; it is in the

careful watching of the details of their lives in their natural surroundings that the value of his work consists.

Mr. Fountain arrives at times at strange conclusions, especially with regard to the adaptation of form and colour to purposes of concealment.

"All my experience," he says (p. 78), "tends to show that coloration is at best but a partial protection. It is none whatever to the human eye, and most naturalists incline to the opinion that animals are quicker sighted than men. An inexperienced person may be deceived, the practised hunter never, unless as the result of his carelessness." "Nature's idea is to create a pleasing and curious variety to gratify the eye of man, nothing more" (p. 135).

But his own pages rebuke him. We are told (pp. 124–5) that ant-bears and sloths

"look, even when you are close to them, so much like a bundle of the dried herbage that they often escape the eye of the hunter and would be sure to do that of the novice."

In another place (p. 137), we read that the ant-bear has a habit of turning its large, bushy tail

"over its back in such a manner that when the animal is squatting on the ground, it is completely hid under it and looks like a tuft of dead grass."

And again (p. 165),

"both the two-toed and three-toed sloth . . . so much resemble a cluster of dead, dried-up twigs in the trees that they are not easily discovered except by experienced eyes."

About six days' journey north of Pernatingas, near Diamantino in Matto Grosso, some caves were discovered which would seem to deserve careful examination. The author found the "entire carcass" of an animal in a mass of stalagmite. He attempted to get it out, but it broke in pieces. It was, he states, a species of guanaco of much larger size than any now living. This is, we believe, the first time that the remains of an animal of the llama group have been reported from Matto Grosso, or, indeed, from Brazil. There were also bones that seemed "to have belonged to gigantic jaguars and deer, and many small animals and bats." He conjectures that another animal was

"of the rhinoceros kind, but if so it was of a hornless species. The bones of tapirs were here in great mass, but of species half as big again as the living kind."

We can scarcely expect the discovery of a South American rhinoceros to be verified, but the list forms an appetising menu for an osteologist.

The author's geology must not be taken too seriously, as a reference to an "extensive formation" of "fused quartz" is sufficient to demonstrate; but it is interesting to note that in a valley in Ecuador he met with "a mass of pure native iron half embedded in the ground"—apparently a meteorite. It weighed five or six hundred-weight and was "in no way oxidised by exposure to the weather." He found a similar mass "on a plain of moderate elevation, as nearly as it is possible to conjecture in the very centre of the southern continent"—a rather vague locality.

Students of the early history of the South American races will be interested in Mr. Fountain's description of a group of huts formed of large slabs of stone on the shore of a lake near the upper Purus. They are not used by the tribes now inhabiting the country, and were, he believes, constructed by a civilised or semi-civilised people since exterminated.

The illustrations appear to have been drawn to the author's descriptions. Though picturesque and creditable to the artist's imagination, they cannot, of course, claim to have any value as accurate representations of natural objects.

J. W. E.

OUR BOOK SHELF.

European Fungus-Flora, Agaricaceae. By G. Massee, F.L.S. Pp. vi + 274. (London: Duckworth and Co., 1902.)

THIS is a condensed synopsis of the mushrooms and toadstools of this and other European countries, and will be of considerable use to expert collectors of these interesting but difficult plants.

The author, in his preface, remarks on the false impression as to the significance of the term "species" which is obtained by studying the fungi of one country only, and he points out that "the Continental species can be sandwiched in between British species."

This statement is well borne out by the contents of the book, in which the European species at present unknown as British are thus packed in between our native forms, and distinctly marked off by square brackets. The method is excellent, and the work, as a whole, well done; but, useful as the book must be to the expert in the field, we are doubtful whether these short definitions of all known species do not increase difficulties for everyone but the expert. Granted that such a work was wanted, we are strongly convinced that an even greater need at present exists for a well-written and accurate account of the relatively few common types or illustrative species, arranged so as to give clearly the principal characteristics of the genera and subdivisions, and familiarise the student with the commoner species, the species being so chosen that the student shall not have to attempt the—to him often impossible—task of discriminating between closely allied and critical forms until he has familiarised himself with the common types.

If *Stropharia siccipes*, Karst., is intermediate between *S. semiglobata*, Batsch., and *S. stercoraria*, Fr., the student is driven to wonder why the three forms are kept as separate species as here defined, and many similar puzzles will arise in the minds of those who find the "species" of Agarics resting on such characters as these short and pithy paragraphs convey. These puzzles will increase as the varieties of such species as *Pluteus cervinus*, Schaeff., and *Agaricus campestris*, L., are compared with species of the genera Hypholoma, Lactarius, Cortinarius, &c.

Excellent as the definitions are, moreover, there are points which require improvement—*e.g.* the genus Lepiota is said to have "Ring present, volva absent" on p. 2; but on turning to p. 7, we read under Lepiota, "Ring free, distinct from the volva." Such ambiguities are trivial to experts, but they are serious difficulties to others, and they could be avoided.

Some questions of termination arise on pp. 206 (bottom) and 227—*e.g.* is it *Ag. rubellus*, Gillet, or *Ag. rubella*, &c.?

In conclusion, the book is fully indexed and carefully arranged, and is well printed on paper so light that, in spite of the thickness of the volume, it can be carried into the field, and it is essentially as a field-book that it can be recommended.

An Introduction to Physiology. By William Townsend Porter, M.D. Part iv. Physiological Optics. Pp. vii + 96. (Cambridge, Mass.: The University Press, 1902.)

THE complaint is often made that the laboratory courses in practical physiology can be of little value to the student, in view of the very limited range of the experiments regarded as possible for a class, and the consequent restriction of the student's attention to one or two chapters of the science. The work before us represents a further step of the creditable effort now being made by Prof. Porter to remove this slur on the practical teaching of physiology and to show that it is possible to give the ordinary student a knowledge of physiology based on his own experience rather than on the mere statement of his teacher or text-book. In this book, comprising less than 100 pages, the student is taught in the first part to determine by experiment the main laws of the reflection and refraction of light, and the formation of the image by convex and concave mirrors, as well as the properties of lenses. In the second part, the physical knowledge so acquired is applied to the determination of the optical qualities of the eye, including the mechanism of accommodation. The last three sections deal with the use of the ophthalmoscope, and its application to the estimation of errors of refraction and other defects in the dioptric mechanisms of the eye.

It would be difficult to imagine a course of study better adapted for the purpose, viz. to give the student of medicine a knowledge which shall fit him for the investigation and diagnosis of the various morbid conditions of the eye. Too many men at present begin to learn their physiological optics only when they are brought face to face with actual cases of disease—a state of things for which the physiological teacher is partly responsible. It is probable that a course such as that laid down by Dr. Porter and extending over about twelve lessons would, if introduced into the London schools, be found to meet a want and would receive appreciation and support. We shall look forward with interest to the appearance of the other parts of this practical physiology, which are to include the special senses, the central nervous system and the whole of chemical physiology. E. H. S.

The Potash Salts; their Production, and Application to Agriculture, Industry and Horticulture. By L. A. Groth. Pp. vi + 291. (London: The Lombard Press, 1902.)

THE Triassic strata yielding potash salts occupy a vast area extending through many of the German States. The potash beds are usually at a considerable depth below the surface. The proving of their occurrence is often a matter of considerable expense and uncertainty, and the establishment of mining operations on a commercial scale may occupy several years. Germany has, however, nearly a monopoly in potash production, and both the production and prices are regulated by a syndicate; the general profitableness of the enterprise is thus guaranteed. The working of a commercial trust is well illustrated by the operations of the Potash Syndicate, one object of which is to supply German consumers with a cheap article while much higher prices are charged to foreigners.

The present book contains a great deal of interesting information as to the potash mines, the mode of working them, the composition of the salts found and the steps taken to prepare various salts for the market. There is also a section of about 100 pages devoted to the use of potash salts for manufacturing purposes, and especially to their use as manures for crops and for garden produce.

The agricultural section is disappointing. No information is given as to the large experience gained in Germany on the use of potash manures in various circumstances; the examples of field experiments quoted are all of them from trials in our own country. The examples selected are naturally those in which the application of potash salts has proved a financial success. Potash manures cannot, however, always be used with profit; on many soils they produce no paying result. Every farmer should, therefore, ascertain by actual experiment what is the effect of potash on his own fields and crops before venturing on any considerable purchase of potash manures.

Nothing is said as to the antiseptic effects of potash salts and their hindrance of the decomposition of farmyard manure. Nothing is also said as to the danger of applying them in spring as a top-dressing to a growing crop, due to the injury caused to the leaves on which the salt falls. The differences in the effects of the various potash salts are also not discussed. Notwithstanding, however, the partial character of the book, it is of real value, as it brings together a great deal of information not easily procured. The use of potash manures in agriculture may doubtless be considerably extended, but, as already stated, the deficiency of the soil in potash should in every case be proved by actual experiment before any use of it is attempted on a large scale. R. W.

Advanced Hygiene. By A. E. Ikin, B.Sc., L.C.P., and R. A. Lyster, M.B., B.Sc., D.P.H. Pp. 300. (London: W. B. Clive, 1902.) Price 3*s*. 6*d*.

THIS work, though styled "Advanced Hygiene," is only written to provide a second year's course of study of hygiene and public health for those who have mastered the contents of a similar small book by one of the authors, entitled "First Stage Hygiene."

Though the matter dealt with is of a very elementary nature, its treatment often leaves much to be desired. It is in some places incorrect and in others misleading. To give an illustration, the wash-down water-closet is said to differ from the short hopper in that "the basin and trap are in one piece," which remark embraces the whole description of a wash-down water-closet.

Many of the illustrations are concerned with sanitary apparatus and arrangements in and about houses, and most of these are badly drawn and otherwise faulty. (Two of them are actually upside-down.) Jennings's plug water-closet is described as a valve water-closet, and Buchan's trap as Buchanan's. The only water filter for domestic use which is illustrated is the Berkefeld, and of this there are no less than six illustrations—all taken from a trade catalogue.

On occasions, different views are expressed in different parts of the same work. It is stated, for instance, on p. 67, that "it seems to be proved that scarlet fever may be directly transmitted from the cow," while on p. 271 it is said that "there is *a possibility* that cows may suffer from a disease akin to scarlet fever." Further, on p. 140, one reads that "the soil *may contain a number of micro-organisms*," while on p. 220 it is (correctly) stated that "the surface soil to the depth of 3 or 4 feet *swarms with bacteria*."

The analytical notes are of little value, and in many respects they are faulty. In a statement of the particulars to be obtained in a quantitative chemical analysis of water, no mention is made of the estimation of chlorine (p. 243).

Material of Machines. By Albert W. Smith. Pp. v + 103. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1902.) Price 4*s*. 6*d*.

AS the life of a machine tool very largely depends upon the nature and quality of the material used in its construction, it is evident that a treatise on this important

subject will be of much use to machine-tool makers. The book under notice is well worth studying; it gives an able description of the metallurgy of iron and steel; it deals with the subject in a concise manner and contains much useful general information. The subject is approached from a scientific point of view, and this is as it should be. Special tool steels are now coming very rapidly to the front; in fact, "Mushet," so long the sheet anchor of the machine shop, is being displaced by these special steels, which only require hardening in a blast of compressed air, thus getting over the risk of cracks due to water hardening and doing infinitely more work. Machine tools have now to be designed to meet the requirements of these new tool steels, more power being required to take the heavier cuts rendered possible by their use. The volume contains much unusually accurate information, but in section 72 we read that the piston rod of a steam engine is of "mild steel"; if a forty-ton steel can be called "mild," then the reviewer is with the author; the same may be said of material for crank pins. Taken as a whole, we can recommend this book. Students of machine design should study it, and those of metallurgy will not waste their time by doing so.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Traces of Past Glacial Action in the Orange River Colony, South Africa.

THE subject of glaciation in South Africa is so interesting and important that I venture to take an early opportunity of directing the attention of geologists to the farm of Brit Koppje, situated about three miles west of Vredefort Road Station, fifty miles north of Kroonstad, in the Orange River Colony. Here, on a koppje, the surface of the rock is so very conspicuously smoothed and rounded that its appearance can hardly, I think, be attributed to the action of any agent other than ice. The general resemblance to photographs of the glaciated rocks at Prieska in Cape Colony recently shown me by Mr. A. W. Rogers, of the Cape Colony Geological Commission, is very great (see a paper read before the South African Philosophical Society by Messrs. Rogers and Schwartz on November 29, 1899).

The bedding planes of the rock are perpendicular and the strike is nearly from north to south. So far as I can recollect (although I was unable to take any accurate observations on this point), they are cut across by the slope of the rounded surfaces, which run rather in a north-easterly to south-westerly direction.

The locality can be very easily visited from Vredefort Road Station. G. E. H. BARRETT-HAMILTON.

Kilmanock House, Arthurstown, Ireland,
December 22, 1902.

Risley's "Tribes of Bengal."

HAVING had occasion to make use of Mr. H. H. Risley's valuable anthropometric data of the tribes and castes of Bengal, some of the "means" for the cephalic breadth, minimum frontal breadth and maximum bizygomatic breadth were incidentally recalculated. This was done whenever the tabulated value for the mean seemed a highly improbable one, and as some serious differences between our means and those given by Mr. Risley were found, it was thought well to point this out for the benefit of those who may be basing their arguments on these data without recalculation. Thus, in vol. i., for the Murmi tribe of the Darjiling Hills, for the mean minimum frontal breadth Mr. Risley gives 113·5, where we find 107·2; for the maximum bizygomatic breadth Mr. Risley's value is 145·9, ours is 138·4.

In vol. ii., Káchi caste of N.W. Provinces and Oudh, for the maximum bizygomatic breadth Mr. Risley's value is 120·8, ours is 130·0. Pathán caste of Panjáb, for the minimum frontal breadth Mr. Risley's value is 117·7, ours is 110·3. These are very serious differences.

As it was important to determine how far these discrepancies reflected on the general accuracy of the work, the means for six tribes taken at random were recalculated. I will merely give a list of the figures for the means:—

Risley.	Recalculation.
132·5	132·57
143·2	143·25
102·6	102·60
132·5	132·59
138·6	138·69
97·7	97·73

There is substantial agreement, except in the decimal figure.

Local Floras of India.

THE writer of the notice of "The Trees, Shrubs and Woody Climbers of the Bombay Presidency," by W. A. Talbot (NATURE, December 18, 1902, p. 148), refers to the need of local floras to supplement Sir Joseph Hooker's "Flora of British India," and names several works of this nature, though not always correctly, which have already appeared. Perhaps I may be permitted to add a few facts on this subject.

In the first place, it should be known that Sir Dietrich Brandis's "Forest Flora of the North-West and Central India" is not, in any sense, an outcome of the "Flora of British India," as it was published before the first volume of the latter work. Further, the late Dr. Trimen's "Handbook of the Flora of Ceylon" was not completed by himself, the last two volumes having been prepared by Sir Joseph Hooker. Among the local floras not mentioned by the writer of the notice in question is Dr. T. Cooke's excellent "Flora of the Bombay Presidency" (see NATURE, vol. lxv., 1901, p. 88), of which two parts have been issued, containing the natural orders Ranunculaceæ to Leguminosæ. Two other important works of the same class are nearly completed, namely, "The Flora of Bengal" and "The Flora of the Gangetic Plain." The former is by Major D. Prain, the Superintendent of the Calcutta Botanic Garden and Director of the Botanical Survey of India, and the latter by Mr. J. F. Duthie, Director of the Botanical Department, Northern India. I am not sure that I have given the exact titles these two books will bear. Then there is the modest but useful "Forest Flora of the School Circle, N.W.P.," by Upendranath Kanjilal. More ambitious among the works supplementary to the "Flora of British India" are the "Annals of the Royal Botanic Garden, Calcutta," commenced by Sir George King and continued by Major Prain. Upwards of 1600 quarto plates illustrative of the flora of India have appeared in this publication, including 450 orchids. Finally, there is the second edition of Gamble's "Manual of Indian Timbers," which contains a vast deal more information than the title would imply. W. BOTTING HEMSLEY.

Herbarium, Kew.

IT was not necessary for our purpose to cite all the works dealing with the Indian flora that were published during the quarter of a century that elapsed between the issue of the first (1872) and of the last volume of Sir Joseph Hooker's "Flora of British India" (1897). In the preface to vol. vii. of that work, the "Forest Flora of the North-West and Central India," by Dr., now Sir, Dietrich Brandis, is mentioned among the works "that have appeared during the publication of the 'Flora of British India,'" and the date assigned is 1874.

The first part of Sir Joseph Hooker's "Flora" was issued in May, 1872, the second in January, 1874, the third in February, 1875; it is in this latter section, at p. 527, that we find the first citations from Dr. Brandis.

Other publications of Mr. C. B. Clarke, the late Mr. Kurz and Colonel Beddome are alluded to in Sir Joseph Hooker's preface, in addition to those cited in Mr. Hemsley's note.

The second edition of Mr. Gamble's "Manual of Indian Timbers" has only reached us quite recently, and, as we believe, since our previous note was written.

THE REVIEWER.

THE SIMILARITY OF THE SHORT-PERIOD BAROMETRIC PRESSURE VARIATIONS OVER LARGE AREAS.

In an earlier number of this Journal (vol. lxvi. p. 248, July 10, 1902), an account was given of the great similarity of curves representing many solar and meteorological phenomena,[1] and it was suggested that their close accordance indicated, not only the intimate relation between solar and meteorological changes, but the importance of the short-period (three to four years) variations common to them all. The variations of solar activity, as indicated by the greater or less number of spots or prominences or by the changes of latitude of the former, were suggested to have such an action on the atmospheric pressure on the earth's surface that when one place recorded an excess, another, nearly antipodal as regards position, showed a deficiency of pressure. Thus the regions specially referred to were those of India and that about Cordoba, in South America.

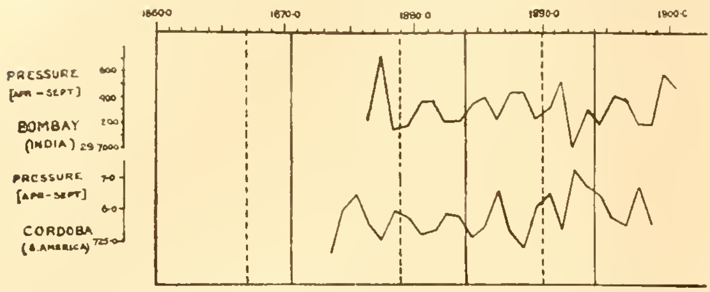

FIG. 1.—In this and all the subsequent figures, the continuous and broken vertical lines represent the epochs of sunspot maxima and minima respectively.

This reversal of conditions, extreme high pressure in one place and low pressure in another at the same moment of time, independent of the yearly or seasonal change, a fact which has since been corroborated by another investigator, as will be seen further on, can be well seen by examining two pressure curves such as those of Bombay and Cordoba (Fig. 1); in each case, the mean pressure for the same months has been used.

In the paper already referred to, it was further pointed out that just as the pressure variations of Bombay were typical of the whole of India, so were those of Oxford (England) or Valencia (Ireland) for western Europe.

With these facts in view, it was important, therefore, to investigate the extent of regions having similar pressure variations, and in the first instance to restrict the inquiry to those areas surrounding India and Cordoba. The results of such a barometric survey were communicated to the Royal Society last October,[2] and it is the purpose of the present article to state the results which have been obtained.

It may, however, first be mentioned that the monthly means of the pressure variations for each station were divided, as in the previous article, into two periods, namely, those months in which the pressures are above and those in which they are below the normal, the normal being the mean pressure for the whole period under investigation in each locality.

Thus, for instance, to take the cases of Bombay and Cordoba, the former has its high-pressure months from April to September and the latter from September to March.

It happens, therefore, in dealing with large areas, that during the same period of time (that is generally, but not invariably, six months) the pressure is above the normal in some places and below the normal in others. In interpreting the curves, therefore, it should be borne in mind that in the one case in which high-pressure months are considered, the crests of the curves denote times of increased pressure, or an excess above the normal conditions, while in the other, where the low-pressure months only are employed, the crests represent the times at which the pressure is not so low as usual.

Dealing first with the region about India, the accompanying curves (Fig. 2) illustrate the variations of pressure which have been analysed. In this set of curves, about the same months are in question, so that the pressure

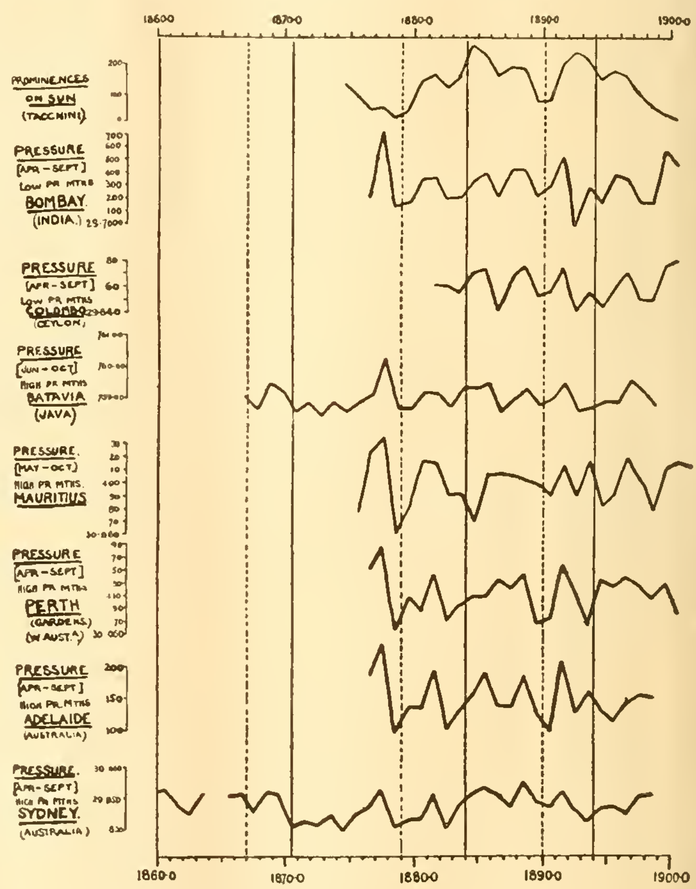

FIG. 2.

variations refer to the low-pressure (summer) months in the northern hemisphere and to the high-pressure (winter) months in the southern hemisphere.

Commencing with Indian pressures (as represented by Bombay), the area was gradually extended to Ceylon

[1] "On Some Phenomena which Suggest a Short Period of Solar and Meteorological Changes," by Sir Norman Lockyer, K.C.B., F.R.S., and William J. S. Lockyer, M.A., Ph.D., F.R.A.S. (Roy. Soc. *Proc.*, vol. lxx. p. 500). [Received June 14, read June 19, 1902.]

[2] "On the Similarity of the Short-Period Pressure Variation over Large Areas," by Sir Norman Lockyer, K.C.B., F.R.S., and William J. S. Lockyer, M.A., Ph.D., F.R.A.S. (Roy. Soc. *Proc.*, vol. lxxi.). [Received October 18, read December 4, 1902.]

(Colombo), Java (Batavia), Mauritius, and finally to Australia (Perth, Adelaide and Sydney).

The striking similarity between these curves shows that over the whole of this area, which includes both north and south latitudes, the same kind of variations is in action, and that therefore the whole region is intimately connected meteorologically.

Attention was next paid to extending the region around Cordoba, which station, as has been previously pointed out, exhibits pressure variations similar to, but the inverse of, those of India.

As Cordoba represents an area south of the equator, and the neighbouring stations exhibit similar pressure variations, a portion of the United States of America was taken as typifying an area with north latitude and in about the same longitude, and a commencement was made along the lowest available parallel of latitude.

This was rendered possible by the kindness of Prof. Bigelow, who forwarded proof sheets of a new reduction of United States pressures which he had just completed.

Treating these pressures in the same way as those for the Indian region, several stations which had the best record were chosen. A graphical representation of the variations of four of these stations (Mobile, Alabama; Jacksonville and Pensacola, Florida; San Diego, California) is given in Fig. 3, and for the sake of comparison the pressure of Cordoba, with the *inverted* curves representing the Bombay pressure and solar prominence variation. This series of curves refers in all cases to the variations of the means of the high-pressure (winter) months (October to March in most cases). At Cordoba, which has a southern latitude, the high-pressure months extend from April to September.

The result of the comparison shows that in this region of the world we have also a large area the pressure variations over which are very similar to one another.

Although the general agreement between the two main sets of curves is most striking, there are minor differences which probably will eventually help to determine those cases in which the prominence effects on pressure are masked by some special conditions.

From these collected series of facts it will be seen that, as regards similar short-period pressure variations, the two regions about India and Cordoba have been considerably extended, and extended on both sides of the equator in each case.

With these two large areas indicating similar barometric variations from year to year, but one showing an excess while the other displayed a deficiency, new questions were at once raised. It required, however, a far more general barometric survey over other areas before such questions could be answered, but so suggestive were the facts observed that, as was stated in the paper, such an inquiry was at once undertaken and is still in progress.

It may, however, here be mentioned that already many other localities have been examined. The Indian area has been extended, for instance, to Aden and Egypt, the former of which places is practically a counterpart of India as regards these barometric variations, while the latter approximates to it. If, on the one hand, we denote land areas the barometric variations of which are very like those of India with a positive sign, and those with a positive query sign (+?) which are more like India than Cordoba; and, on the other, pressures similar to those of Cordoba with a negative sign, and those which are more like Cordoba than India with a negative query sign (−?), then it is found that, so far as barometric observations which have as yet been examined are concerned, the earth's surface may be divided approximately into two main regions, one positive the other negative, separated from one another by areas the pressure variations of which may, according to the above notation, be described as positive and negative queries (+?, −?).

It is fortunate that while this reduction and collation of barometric facts has been pursued in this country, another investigator has been working on similar lines in the United States, making it possible to compare results. In fact, Prof. Bigelow's research,[1] which was received some time after the above-mentioned was communicated to the Royal Society, has led him to very nearly

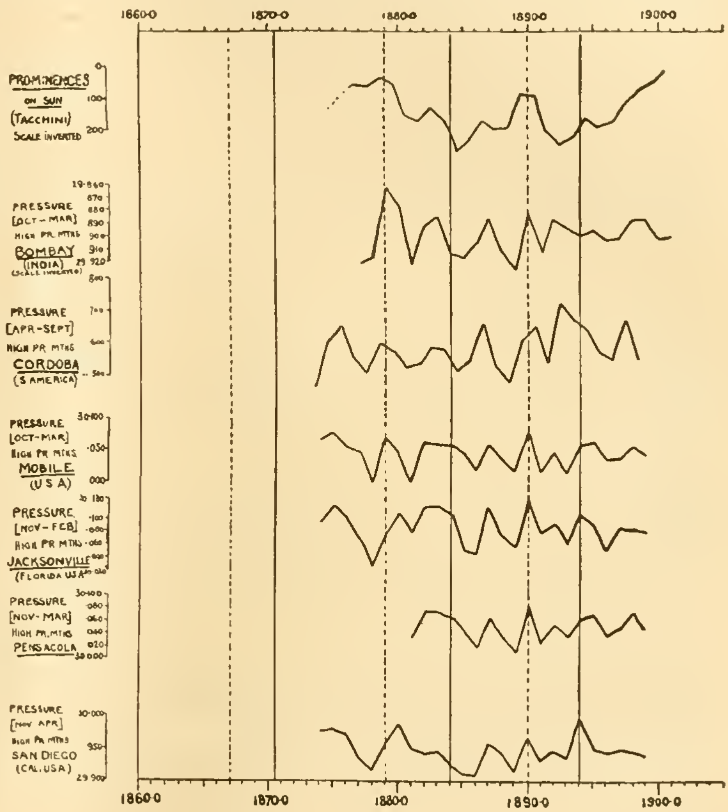

Fig. 3.

the same conclusions as those stated in the present article, if some minor differences be excluded. One of these differences arises from the fact that he has formed the mean of barometric observations made over an area including north-east China, Japan, north India, central India, south India, Batavia and Mauritius, while there seems evidence to show that the whole of India, Batavia and Mauritius behave differently from Siberia, northern China and Japan. This, however, he somewhat concedes later in his article as he points out that "in Siberia and Russia the synchronism begins to break a little . . ." Another difference will be referred to a little further on.

Apart, however, from these, Prof. Bigelow finds that "the same pressure variations, in fact, prevail over very

[1] *Monthly Weather Review*, vol. xxx. No. 7, p. 347, "Studies on the Statics and Kinematics of the Atmosphere in the United States, No. vii., A Contribution to Cosmical Meteorology" by Prof. Frank H. Bigelow (dated August 12, 1902).

large districts of the earth though varying from one region to another."

He says further :—

"If we compare the successive pressure groups with the prominence curve, it will be seen that India and south-eastern Asia are in very close synchronous agreement. This synchronism extends also to New South Wales, the Indian Ocean and even to South Africa. In Siberia and Russia, the synchronism begins to break a little and seems to be transferred somewhat towards the right, although this may be due in part to defective data. In Europe and in the United States, while the same curve is developed as to the number of the maxima and minima, the synchronism becomes more irregular. In South America, on the other hand, the synchronism is resumed very distinctly, but the *entire curve is reversed as referred to India and the Eastern Hemisphere.* Thus we perceive that around the Indian Ocean the synchronism is clearly developed ; it weakens in Europe and North America, and it becomes a distinct reversal in South America . . ."

From the above, it will be seen that Prof. Bigelow also demonstrates the existence of large areas which are in excess and in defect of pressure simultaneously, while others are not in such close synchronism.

It may here be mentioned that he treats North America as a whole and gives a curve showing the short period variation of pressure. It is of interest, however, to note, as has been shown earlier in this article, that the southern

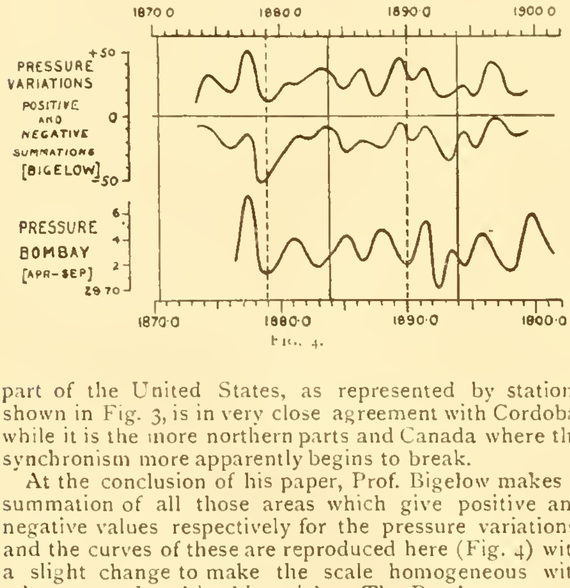

FIG. 4.

part of the United States, as represented by stations shown in Fig. 3, is in very close agreement with Cordoba, while it is the more northern parts and Canada where the synchronism more apparently begins to break.

At the conclusion of his paper, Prof. Bigelow makes a summation of all those areas which give positive and negative values respectively for the pressure variations, and the curves of these are reproduced here (Fig. 4) with a slight change to make the scale homogeneous with others reproduced in this article. The Bombay pressure curve has also been added, and a smooth curve is drawn through the points instead of connecting them with straight lines as in Fig. 2.

The parallelism of the two upper curves indicates, as Prof. Bigelow points out, that "the values do not cancel each other," and that as "the curves match fairly well with the prominence curve, . . . I take it to mean that *some external force is at work to raise and lower the total atmospheric pressure by a small amount from year to year.*"

The two investigations are in agreement as regards the following three main points. First, the close connection between solar activity and barometric pressure ; second, the great extent of areas over which very similar pressure variations exist ; and, third and last, the presence of two large areas the pressure variations over which are the reciprocal of each other.

It is interesting to remark that, from the comparisons of the pressure variations over the different areas, the authors of both these investigations were led to consider whether these suggestive features were connected with the idea of a periodical see-saw of pressure extending over a few years between these two nearly antipodal areas, or whether we were in presence of a barometric wave travelling round the earth.

There seems little doubt that when more facts are collected these reciprocal pressure variations will in time play an important part in forecasting the general features of seasons and thus supply meteorologists with another means of helping them in their difficult task.

The value that must in future be placed on observations of the sun which inform us of his state of activity or quiescence, since these pressure variations are apparently so closely connected with them, cannot any longer be laid on one side, but must be recognised as of a high order of importance. WILLIAM J. S. LOCKYER.

EDUCATION IN GERMANY AND ENGLAND.

MANY people in this country, eminent men of science and literature, leading men in commerce and industry, and politicians who place efficiency before party shibboleths, have for many years felt apprehensive as to the condition of our national system of education. For a long time, they have been speaking and writing upon the subject and endeavouring—by pointing to advancements and achievements of other nations who have put their educational house in order—to stir up the nation at large to realise the enormous interests which are at stake. For many years, the warnings fell upon deaf ears and the advocates of reform were either looked upon as bores or cranks. To-day all this is changed, and it is almost unfashionable not at least to talk about education ; this does not, however, necessarily imply a knowledge of the subject.

Were it not for its terrible prolixity, those who really desire to know the ins and outs of the German educational system could not do better than carefully study vol. ix. of "Special Reports on Educational Subjects," dealing with Germany, which is issued by the Board of Education. A mere glance at this report shows that, although the present system of education in Germany has been of such incalculable value to the Empire, yet those interested in education in that country—and their name is legion—are questioning whether their system is after all so good as it might be. There are many in Germany who think that some of our freedom from restraint would give a breadth of idea and a broadness of horizon which is not obtained by their methods of abstract reasoning and rigid exactness.

The report embraces primary, secondary and technical education. The first 200 pages consist of dissertations by different writers upon different aspects or phases of education. The first of these is by Mr. M. E. Sadler, who has compiled the report, upon "The Unrest in Secondary Education in Germany and Elsewhere." This also includes a comparison between English and German methods. Mr. Sadler admits at once that we have an insufficiency of good secondary day schools and that education at our public schools is not what it should be. Further, our technical training is defective, and, owing to our comparative neglect of national education for many years past, "as a nation we are much less intelligently interested than the Germans in methods of instruction." It is true that German and French methods are now very much advocated in this country, but the great difficulty is that those who desire us indiscriminately to imitate and introduce curricula and methods from other nations seem totally unable to realise that if we wish for an exact copy, we must at the same time reproduce the social and economic conditions of these other countries.

The old idea in England was, teach a boy to be manly, teach him not to be a sneak and a coward, and at the same time give him a smattering of education, then let him be placed in the Army or Navy or business and, come what may, character will carry him through. There is no doubt about it that our public-school life, with its traditions and the *esprit de corps* which it engenders, has had much to do with moulding character, and in past generations, when other nations were settling their internecine troubles and it was simply a question of staking out claims for posterity, this style of education was satisfactory enough. But Germany and other nations, as soon as they had settled their internal struggles, proceeded at once to build up a system of national education which has had far-reaching effects upon many of their most important industries. Not only has German education had such enormous influence upon their own industries, owing to the introduction of scientific methods, but it has likewise been felt in this country, because our manufacturers and traders, not having been taught to believe in scientific training, have stuck to old-time methods, with the disastrous result that in many branches of industry we are unable to compete with the scientific German. In Prussia, all the secondary schools are upon the same lines. The Prussian knows the meaning of a secondary school; it would puzzle an Englishman to define one. The standard is practically the same in all the Prussian secondary schools; here we have no standard at all. English masters as a rule are devoted to their schools, German masters to education. An English boy loves his school; a German boy has not the same feeling of *esprit de corps*, but looks upon his school as an establishment for obtaining knowledge. We lay stress on character, the Germans on knowledge. There are good points in each. The tendency in our schools to make the school standard one of proficiency in sport, and to make fun of earnestness and to chaff those who desire to obtain knowledge, is not good. That objectionable expression "don't talk shop," which is often hurled at the head of those who, through a sincere interest in their business or profession, wish to exchange ideas with others, is the outcome of this characteristic. On the other hand, the Germans would undoubtedly gain if they had more freedom from restraint and were not so bound down by hard and fast rules and regulations.

Other nations have realised that an education which was sufficient fifty years ago is antiquated and of little value in the present day, when science and learning have made such enormous strides. In matters of educational reform, or of accepting new views or theories, we have, as a nation, always shown a conservative spirit. When learning was only advancing slowly and new theories were propounded which had very little foundation of fact to rest upon, doubtless a conservative and cautious policy led in the long run to greater solidarity and was better than being too hasty in taking up new ideas solely because they were new, but which would almost immediately require to be discarded for some newer theory. But now, since the growth of knowledge, resting, as it does, on a broad foundation of experimental fact, is so rapid, it is absolutely essential that we should alter our methods in order to keep abreast of the times.

Fifty years ago, a boy might spend the bulk of his time upon the study of classics and yet be fitted to take his place in business or commerce. To-day, classics alone are of little use. Here it should be pointed out that in Germany the study of classics is not neglected; indeed, considerable stress is laid upon that study. Science is, as a rule, not taught until the boys have at least obtained a thorough general grounding in classics, and there are those in Germany who would make the classical education more thorough than it is at present. The following instance illustrates how thorough, in general, the study of Latin in Germany must be. An Englishman, a friend of the writer's, went to study in Bavaria and had no knowledge of the German language. A nephew of his landlady, a boy of about fifteen, was studying at a public secondary school, and although the Englishman was unable to make his landlady understand his wants, he was able by means of Latin to converse with her nephew and so have his wants attended to.

In a Prussian secondary school, a master has to know a great deal more of the subject which he has to teach than an English master in a similar position. In England, erudition is considered of far less importance than activity of mind and body and success in sport. We often say, "All work and no play makes Jack a dull boy"; we seem to forget the converse, that much play and little or no work unfits the boy for the struggle in after life. On p. 215 of the report, we find the following quotation from the remarks of a Frenchman:—"A boy at an English public school has qualities which a French schoolboy does not possess, but those qualities are moral and not intellectual. In English education there is a very weak point—and that is *instruction*." An educational system in which the weak point is instruction surely requires overhauling.

The object in our schools should be to teach that the most lasting form of pleasure is to be found in work well done. R. L. Stevenson once said, "I know what pleasure is, for I have done good work." It has been stated that one of the reasons why the Americans are so successful in the present day and seem to be carrying all before them is that "they find their pleasure in their business."

Centralisation is the backbone of the German and French educational systems. Here we have found that centralisation spells *red tape*, and now with the swing of the pendulum the cry is for decentralisation. Wholesale decentralisation will probably spell chaos. It is essential that we should have a satisfactory primary education, to be followed up by an efficient and carefully planned scheme of secondary education, but it is very doubtful whether the carrying out of even the finest imaginable system of education could be left entirely to the local authorities or to the teachers themselves. It would not be satisfactory to bind down teachers to a hard and fast interpretation of any code or system. Scope must be left for individuality, not, however, for eccentricity.

There is one thing the report makes abundantly clear, and that is that we have much to learn from the Germans; there are many things we might adapt, but very little that we could copy. There is a tremendous outcry in this country for specialisation, and many advocate early specialisation. Early specialisation is not at all believed in on the continent. In the continental university or polytechnic, specialisation is not allowed until a scholar is able to show that he has a thorough general education. We ought to have some equivalent to the German "Abiturienten," or leaving examination. Unless such an examination has been successfully passed, the student cannot enter a university or polytechnic and take his degree or diploma. Further, in obtaining situations in business houses, preference is invariably given to those who have successfully passed this examination; indeed, many business houses will not take men into their employment who have not passed this satisfactorily.

Sixty-five pages of the report are devoted to the "Measurement of Mental Fatigue." We find that the systematic study of mental fatigue has been taken up in a spirit of earnest, scientific inquiry; and it is worthy of note that post-mortem examinations have shown "that those parts of the brain which serve the purpose of systematic thought, commonly known as the reasoning powers, are the last to mature." The question of what constitutes mental fatigue must always be one of great difficulty. If the laws of hygiene are obeyed

and the subject is sufficiently clothed and fed, he will probably be able to accomplish a very much larger amount of mental work, without being over-strained, than would be the case if these conditions were neglected.

In Germany, the question of dealing with over brain work is probably more pressing than it is in this country, because the brain is often over-exercised, while there is an insufficiency of physical exercise. In England, I am afraid, it is more often a question of physical fatigue than one of mental strain with which we are faced. But of course, when the teaching system is "unintelligent"—that is, one of *cram*—the poor brain must get terribly wearied.

Mr. Sadler has compiled the report with great care, and the portions which he has himself written are marked by a refreshing breadth of view not always to be found in Government reports. It is probable, however, that the object would be better attained if these reports were more condensed. F. MOLLWO PERKIN.

TIDAL CURRENTS IN THE GULF OF ST. LAWRENCE.

FOR many years past, the Canadian Government has been prosecuting an accurate survey of the complicated tides and tidal currents of the Gulf of St. Lawrence. The Tidal Department, under the able directorship of Mr. W. Bell Dawson, has already done much excellent work in this field, although, doubtless, much yet remains to be discovered. In the tidal report for the present year, Mr. Dawson will describe the results of a careful analysis of the remarkable tidal currents which are met with in Northumberland Strait south of Prince Edward's Island. At most places, the times of the changes of tidal currents bear a more or less constant relationship to the times of high and low water, but in this channel the changes are found to be largely governed by the moon's declination. As Mr. Dawson remarks:—"This is very confusing to the mariner, as the turn of the current in relation to the tide is out of accord with the moon's phases, and has thus no fixed relation to the spring and neap tides. The greatest apparent irregularity is when the moon's declination is at its maximum; and this occurs sometimes at the spring tides and sometimes at the neaps. The ordinary navigator takes refuge in the conclusion that the currents are chiefly influenced by the wind."

Diurnal tides are ruled by the declination of the moon, and it would seem that there must be at this place a large diurnal inequality which manifests itself more by current than by variations of height.

Those who are interested in this subject will do well to refer to Mr. Dawson's forthcoming report.

G. H. D.

JOHANNES WISLICENUS.

THE generation that laid the foundation of organic chemistry has almost become a thing of the past, and at the close of last year one of the few remaining links was broken by the death of Wislicenus.

Not long since, the University of Leipzig was mourning the loss, at a venerable age, of a distinguished physicist; to-day the chair which was made famous by that "wahre Bearbeiter" Kolbe is vacant, and a name which will ever be illustrious in the history of spacial chemistry has been added to the classical traditions of this great seat of learning.

The news has come not as a sudden shock, for of late years the health of the venerable Geheimrath has been visibly declining, and waning strength and feeble gait warned his many friends that his working days would soon be over; none the less poignant, however, is the grief felt by all who have had the privilege of sharing his friendship or coming under the influence of his impressive and genial personality.

Johannes Wislicenus was born on June 24, 1835, at Klein-Eichsted, in the Prussian province of Saxony; when he was five years old, his father, a pastor, was transferred to Halle a. Salle, and there the boy received his first impressions of school life. At the "Frankesche Stiftung," a school which has since become celebrated, he remained until the age of eighteen, and at Easter, 1853, having passed his Maturitätsexamen, he entered the University of Halle with the intention of devoting himself to the study of natural science. His project was, however, soon frustrated. The political horizon was still clouded over, and in consequence of certain intrigues, his father, in the autumn of the same year, was compelled to fly the country; he found a home for himself and his family, as did so many refugees of that time, in the United States. In the following year, Johannes was appointed assistant to Prof. Horsford at Harvard University, Mass., and in 1855 became lecturer at the Mechanics' Institute, New York, with a laboratory at his disposal.

It was thus that he acquired that command of English which was such a source of wonder to his foreign students in later years.

In 1856, he was able to return to Europe, and resumed his interrupted studies at the University of Zurich, where he "promovierte" in 1860 and was appointed Privatdocent at the Polytechnic.

In 1861, he became professor of chemistry and mineralogy at the "Kantonale Industrieschule." Four years later, he received the honour of a chair at the University of Zurich, and in 1871 was elected by the "Bundesrath" as director of the Polytechnic in that town. In the following year, he was chosen to succeed Ad. Strecker at Würzburg. There he remained until 1885, and it was during this time that he carried on his classical researches on the constitution of acetoacetic ether and so established his reputation on a firm basis.

The year 1884 witnessed the death of Kolbe and the call of Wislicenus to Leipzig, where he remained until the end. As was pointed out by a writer recently in this Journal, "there is a curious irony in the thought that his first work there should have been directed towards the extension of the theory of Van 't Hoff, whom Kolbe had regarded with such contempt."

Of his scientific work, space will only permit the barest outline. His researches were confined almost exclusively to the domain of organic chemistry, most of them appearing in *Liebig's Annalen der Chemie*. The constitution of lactic acid, on which he worked from 1863 to 1872, establishing the identity of structure for the two different substances fermentation- and para-lactic acids, first brought him into prominence among chemical workers and impelled him to seek an explanation of the metamerism in the spacial relations of the atoms within the molecule. His interest in acetoacetic ether, to which reference has already been made, resulted in a detailed investigation of its reactions and of its value as a synthetic agent; these have gone far to stimulate the study of this most interesting compound, and are of importance, if for no other reason, for the light they throw on the still open question of its constitution.

It was in Leipzig, however, that he achieved his great work. In 1887 appeared his famous memoir, "Über die raümliche Anordnung der Atome in organischen Molekulen," to account for the phenomena of "geometrical isomerism." According to his hypothesis, which was an extension of that formulated independently by Le Bel and Van 't Hoff in 1874, "the centre of gravity of a carbon atom was regarded as situated in the centre of a tetrahedron, and its four affinities at the four corners." When two atoms were linked together, Van 't Hoff, and

after him Wislicenus, assumed that both were capable of rotating in opposite directions about a common axis; this possibility ceased, however, with a double or treble linking of the carbon atoms. Wislicenus further called into play the action of certain "specially directed forces the affinity-energies" which "determine the relative positions of the atoms to one another in the molecule."

The *Annalen* of these years contain a large number of papers worked out in the Leipzig laboratories under his direction, in which the reactions of maleic and fumaric acids, the tolane dichlorides and dibromides, mesaconic and citraconic acids, the crotonic acids, the α-chloropropylenes, &c., were carefully investigated, and the facts shown to be in agreement with those demanded by theory.

The hypothesis naturally evoked much criticism; Wislicenus's controversy with Fittig (*Liebig's Annalen*, 1892, cclxxii. 1–99) is still fresh in the minds of chemists, and it must be admitted that Michael has obtained results which it has not yet been found possible to reconcile with the theory. But when all is said, there can be little doubt that up to the present it remains the simplest and most comprehensive explanation adduced. Even if the theory should ever be disproved, Wislicenus's memoir will always hold a place among the classics of the science as a model of careful reasoning and literary skill, and as an epitome of one of the most laborious researches of that period.

Now, however, is not the time, nor is this the place, to dwell in any detail on his scientific papers; the above indication of the direction which his research took must suffice; it would be presumptuous to attempt to estimate the value of his work; enough that, among the great names in the history of chemical science, Wislicenus will stand with Bunsen and Kekulé and Victor Meyer and such names as made the nineteenth century what it was.

We do not wish to enter into a panegyric of his character; such things belong rather to the columns of a daily paper and to the exaggerated estimates of mediocrities; but a word as to his human aspect—and he *was* a man of wide sympathies—will not be out of place. In politics, he was an ardent admirer of Bismarck, and had little tolerance for the social democrats of latter days; not that charitableness was lacking in his disposition, for many were the kindly acts that he performed. He was fond of children, and when his own family had grown up and he was left alone with his daughter, the cheerful presence of a little niece helped to relieve the gloom that the tragedy of his domestic life had cast over the later years. To music he was almost insensible, and Wagner was to him nothing more than a confusion of sounds. He was present at the first performance of "Siegfried," but left in the middle of the second act with a violent headache. Literature was his one refuge in the intervals of work, and when troubled with insomnia, from which he suffered much, he would pass the hours in his well-stocked library. It is related that at one of his weekly dinner parties, to which all his research students were invited in turn, a youth of an inquiring turn of mind, desirous of probing the extent of the professor's knowledge, read up an almost forgotten author and tackled him on the subject when the cigars were produced; great was the student's chagrin on discovering that it was one of his teacher's favourite authors and at having to sit through an impromptu half-hour's lecture on the author's peculiarities of style. This youth never carried his investigations any further. With his students, Wislicenus was always popular, and though they christened him at one time the "Schmier-Director," from the number of tarry residues that the arbeits were producing, that did not detract from the affection and esteem in which he was held. In his daily round of the research laboratories, he was ever ready with words of sympathy and encouragement that went far to allay the soreness and disappointment of repeated failures; his kindly suggestions have stimulated many to greater efforts.

In 1898, the Royal Society awarded him the Davy medal, and his death makes a vacancy in its list of foreign members.

The loss will be felt not in Germany alone, for his students came from all parts of the world, and while men of science will remember him as one of the founders of stereochemistry, his disciples will look back on him as one of the "influences" of their lives, as a man of broad sympathies and great powers, as an example to emulate and as a memory to inspire.

NOTES.

AMONG the names included in the long list of "Durbar Honours" published on New Year's Day, we notice the following:—Dr. George Watt, C.I.E., officer in charge of the Economic and Art Section of the Indian Museum, Calcutta, has had the honour of knighthood conferred upon him. Dr. W. R. Hooper, C.S.I., President of the Medical Board at the India Office, and Sir Colin Campbell Scott Moncrieff, K.C.M.G., President of the Indian Irrigation Commission, have been made Knight Commanders of the Star of India. Colonel St. George C. Gore, Surveyor-General of India, has been made a Companion of the same order. Dr. B. Franklin, Director-General Indian Medical Service, and Mr. John Eliot, F.R.S., Meteorological Reporter to the Government of India and Director-General of Indian Observatories, have been promoted to the rank of Knight Commanders of the Order of the Indian Empire. Major A. W. Alcock, F.R.S., Superintendent of the Indian Museum, and Prof. J. C. Bose, Presidency College, Calcutta, have been made Companions of the same order. Major David Semple, Director of the Pasteur Institute, Kasauli, has been awarded the Kaisar-I-Hind Medal for Public Service in India.

A GERMAN newspaper records the following exemplary incident, apropos of a recent act of the Kaiser, in appealing to his people for support in a good work. Dr. Dohrn, of Naples, having appealed with little result to the German Minister of Education for financial aid in the extension of his world-famed biological station, sought an interview with the Kaiser. Remarking sympathetically that he could not provide all that Dr. Dohrn desired from his private purse, the Kaiser furnished him with a donation form, headed by himself and a contribution of 1000*l.*, commanding that it should be circulated among the leaders in Berlin society, for return to the Kaiser in person. The result was that within a few days the magnificent sum of 15,000*l.* was subscribed.

MR. HERBERT KYNASTON has been appointed by the Colonial Office director of the Geological Survey of the Transvaal.

M. EDMOND PERRIER has been appointed to the chair of comparative anatomy at the Paris Muséum d'Histoire Naturelle, and M. Pierre Marcellin Boule to the chair of palæontology at the same institution.

A MESSAGE from the *Times* correspondent at Ottawa states that the promoters of the Canadian Marconi Company hope by the end of next summer to have a complete system of wireless telegraphy in operation throughout Canada, extending from the Gulf of St. Lawrence to the Pacific Coast.

MR. MARCONI was entertained at a banquet at Sydney on December 30 by the citizens of Cape Breton Island. Reuter reports that in responding to the toast of his health, Mr. Marconi said that when his system of wireless telegraphy was further developed, it would be possible for ships in distress to signal passing ships. The cable companies, when they began, charged pounds per word; they were now down to shillings,

and his starting at ten cents might soon lead to a charge of one cent per word and thus bind England and her colonies more closely together.

THE *Daily Mail* states that Sir Ernest Cassel has offered to give 40,000*l.* towards the study and investigation of ophthalmia in Egypt.

THE death is announced of M. Pierre Laffitte, who, since 1893, has filled the chair at the College de France for the exposition of the general history of science.

AN anti-tuberculosis union for Austria has been formed, with Count Lützow as president. The Vienna correspondent of the *Times* reports that nearly 5000*l.* has already been received in subscriptions, and the Government has promised the fullest support in combating the disease.

THE death is announced of Prof. Dr. Max Schede, professor of surgery at the University of Bonn, to which post he was appointed in 1895. During the time that Prof. Schede was organiser of the surgical section of Hamburg Hospital, he made it his aim to develop the system of antiseptics introduced into surgery by Lord Lister.

MR. OTTO HILGER, whose death we announced last week, was born at Darmstadt on January 20, 1850, where he passed his apprenticeship under his father, who was the master of the mint. At eighteen years of age, he went with his brother, the late Mr. Adam Hilger, to Paris, where they started a workshop, doing much good work for the observatory. At the outbreak of the Franco-German war in 1870, being Germans they had to leave Paris and came to London. In a few years, they were able to start a small business as scientific instrument makers, and the name of Hilger soon became well known in the scientific world. In 1888, Mr. Otto Hilger was appointed by Lord Blythswood to take charge of his private laboratory, where he was until 1897, when the death of his brother compelled him to return to London to carry on the business, though this necessitated leaving partially completed a dividing engine for ruling diffraction gratings which he had been constructing under Lord Blythswood. During recent years, the demand for a high degree of accuracy in scientific instruments has greatly increased, and many men of science will regret the death of a maker who was able to appreciate the necessity for refinements in workmanship.

ON Tuesday, January 13, Prof. Macfadyen will deliver the first of a course of six lectures at the Royal Institution on "The Physiology of Digestion." On Thursday, January 15, Mr. A. J. Evans will begin a course of three lectures on "Pre-Phœnician Writing in Crete, and its Bearings on the History of the Alphabet." The Friday evening discourse on January 16 will be delivered by Prof. Dewar, on "Low Temperature Investigations." On January 23, Dr. Tempest Anderson will lecture on "Recent Volcanic Eruptions," and on January 30 Prof. W. E. Dalby will lecture on "Vibration Problems in Engineering Science."

ACCORDING to a Reuter message from San Francisco, advices from Corinto (Nicaragua), dated December 15, state that the volcano Santiago, near Granada, was then in active eruption. At night the sky was lit up by the volcano, and great havoc had been wrought. Momotombo, on Lake Managua, was also discharging clouds, and the volcano Izalco, in San Salvador, was in more active eruption, clouds and lava issuing from the crater at short intervals. At night a brilliant spectacle was presented, the lava pouring down the side of the mountain looking like a stream of fire. A telegram from Valparaiso states that it is reported that five volcanoes in the province of Llarquihue are active.

THE Moscow correspondent of the *Standard* states that a well-marked record of the recent earthquake at Andijan was obtained by the seismological instruments at the observatory there. The time recorded was 11 a.m., that is, about 8.30 a.m. Greenwich time. Andijan is the second largest town in the "Territory" of Fergana, and had not less than fifty thousand inhabitants at the time of the earthquake.

DURING the past ten months, the Odessa correspondent of the *Standard* points out, Transcaucasia and Transcaspia have been visited by several severe earthquakes. In February last, Schemakha, on the Caspian side of the Caucasus, was laid in ruins by a series of violent earthquakes and volcanic disturbances, in which upwards of three thousand people perished. In July, a similar calamity desolated several districts in Kashgar, involving the loss of some six thousand lives. Those events have now been followed by the destructive series of earthquakes in the districts of Novi-Marghelan and Andijan. According to the latest reports, the loss of life is equally as appalling as that at Kashgar. A few days previous to the dreadful event in Andijan, a series of slight earthquake shocks was felt at Schemakha, the site of the disaster in February last.

PROF. ROBERT KOCH and two assistants, Surgeon Dr. Kleine, of the Prussian Headquarters Staff, and Dr. Neufeld, of the Prussian Institute for Infectious Diseases, are on their way to investigate cattle plague in Rhodesia. To the Berlin correspondent of the *Daily Mail*, Prof. Koch has remarked:—"I contemplate my mission with more or less misgiving, because the Rhodesian plague is of an absolutely mystifying character. Such symptoms as I have so far examined indicate that the disease is wholly different from any species of rinderpest that has ever come under medical observation. What is peculiarly baffling is that the Rhodesian plague dates only from the late war. The cattle imported from Egypt, Australia and South America, which it was supposed would prove immune, have fallen early victims to its ravages, which threaten to denude the entire colony of live stock. While in South Africa, I shall not neglect the opportunity of continuing my tuberculosis experiments with the view of adducing still more positive evidence of my theory of the non-communicability of bovine tuberculosis to human beings, which I, of course, adhere to resolutely."

CAPTAIN BOYD ALEXANDER has just returned to England, after a short visit to the west coast of Africa, where he has been collecting birds and mammals on the islands of St. Thomas and Fernando Po, in the Bight of Biafra. Captain Alexander has obtained altogether nearly 400 specimens, and is expecting more from a collector that he left in Fernando Po. The results of his work as regards birds will probably be published in the *Ibis*.

MR. J. S. BUDGETT, Balfour student of the University of Cambridge, has returned to England from Lake Albert (where he has been engaged in studying the development of the Polypterine fishes) by the Nile route, and will give an account of his expedition at the scientific meeting of the Zoological Society on January 20. Not having been altogether successful in Uganda, Mr. Budgett will probably make another visit to the Upper Gambia, where he has better prospects of obtaining the required information, in the course of the present year.

MR. W. G. DOGGETT writes from Entebbe (November 5, 1902) that he was then preparing to start for the southern frontier of Uganda, to take up his post as naturalist to the Anglo-German Boundary Commission under Major Delmé Radcliffe. The expedition will start from the shores of Lake Victoria at 1° S.L., and will define the boundary between Uganda and German East Africa as far west as the Semliki

River. In the Semliki Forest, Mr. Doggett hopes to be able to obtain fresh specimens of the new African mammal (*Okapia johnstoni*), which are much required at South Kensington.

THE Institution of Electrical Engineers has issued the preliminary programme of the visit to Italy to be made this spring. It is proposed to leave London on April 2, and the first technical visit will be to the Valtellina Railway and power-house on April 4. At Como also the tomb of Volta can be visited the next day. On April 6, the party will leave for Milan, travelling *viâ* the Milan-Varese Electric Railway and visiting the works of Messrs. Tosi, at Legnano, in passing. On April 7, the Paderno power-house will be inspected. On April 8, visits will be made to various places of technical interest in Milan, including the Technical High School, and on the next day to the power-houses at Vizzola and Tornavento. The party will break up on Thursday, April 9, or on the Friday morning (Good Friday).

AMONG the many papers of interest in the December number of the *Geographical Journal* may be specially mentioned Dr. Stein's account of his explorations in Chinese Turkestan, and the readers of NATURE will not fail to note the importance of his discovery of inscribed wooden tablets on the Niya River site. Here, in a small decayed building, he found more than 200 documents on wood of all shapes and sizes. Besides tablets with the Indian Kharoshthi writing, he unearthed several narrow pieces of wood bearing Chinese characters, and many of the former were still protected by the strings with which they were originally tied and bore clay seals. On the seals, we have figures of Pallas Athene, with shield and ægis, Eros and Athene Promachos, and these prove beyond all doubt the influence which classical Western art has exercised even in distant Khotan. Many of the documents bear dates which are mentioned in connection with the names of rulers, and the texts, which seem to be written in an early form of Indian Prakrit, cannot fail to throw great light on the early, unknown history of the district wherein they have been found. It is important that the materials which Dr. Stein has secured should be worked thoroughly, for they may contain information concerning the frequent communication which must have existed between the East and the West during the early centuries of the Christian era.

THE unfortunate fatal accident which occurred at the Fulham Public Baths on December 23 serves to show how dangerous an electric shock may be when the conditions are such that really good contact is made. In this case, two bathers were killed by standing up in their baths and putting their hands on a metal rail running along the top of the partition between the baths; on top of this rail ran the iron pipes containing the electric-supply leads. It seems that there was leakage, possibly in a faulty lampholder, to these pipes, which were insufficiently "earthed." The bathers therefore completed the earth through their bodies to the bath itself, and thus received a shock which, in spite of the fact that the pressure could only have been something like 170 volts, had fatal results on account of the very good contacts which existed. The circumstances of the case are altogether exceptional, and there is absolutely no need for users of electric light to take any alarm. The moral to be drawn is that in an installation of this kind, where it is possible for people to make direct contact between their damp skin and parts of the installation, more care should be taken in design and supervision to prevent any possibility of contact with any live metal.

THE outbreaks of typhoid fever at Winchester and at Southampton again direct attention to the possibility of the typhoid infection being spread through the agency of shell fish, in these instances through oysters. Dr. Nash, in a report on an outbreak of typhoid fever at Southend-on-Sea, finds that the incidence of the disease was thirty-six times as great among shell-fish consumers as among those who do not eat shell-fish, and expresses the opinion that if the eating of shell-fish were abandoned in Southend, the incidence of typhoid fever would lessen by fully one-half. In the Southend outbreak, cockles were mainly responsible for the spread of the infection.

A LARGE portion of the contents of the January number of *Climate* is devoted to a consideration of the possibility of stamping out malaria. Major Ronald Ross discusses the prevalence of malaria at Ismailia, and comes to the conclusion that if the mosquitoes in the district were even partially eradicated, as might easily be done, malaria would almost disappear. Sir William MacGregor describes the Italian campaign against malaria, and draws attention to the prophylactic use of quinine, the protection of dwellings with wire gauze, the cultivation of the soil and the drainage of swamps as means of diminishing the prevalence of malaria.

AT an international maritime congress recently held at Copenhagen, M. Willaume-Jantzen, subdirector of the Danish Meteorological Institute, contributed an interesting paper on the climate of the coast of Iceland, based on eighteen to twenty-two years' observations at four representative stations—Vestmannoe (south), Stykkisholm (west), Grimsey (north) and Papey (east). Generally speaking, the lowest mean barometric pressure in the north Atlantic lies to the south-west of Iceland, and to the north-east of the island there is another area of mean low pressure, but a little higher than that on the south-west. These two areas determine the prevalent winds on the east coast, which blow with nearly equal persistency from north-east and from north-west. But from its position with regard to the advance of barometric depressions from west to east in the Atlantic, the pressure in Iceland is subject to sudden and great variations, causing frequent storms, the average annual number of days of storm on the east coast being seventy-five. Generally speaking, the summer climate on the coast is fresh and the winter mild, but the latter may be very severe with northerly winds and the approach of polar ice. In some localities, fog is very prevalent; at Berufiord, near Papey, it occurs on 212 days, but at Stykkisholm on nine days only. Rainfall is heavy on the south and light on the north; at Vestmannoe there are 225 days on which rain falls on a yearly average.

THE volume containing the meteorological observations and results for the United States Naval Observatory, Washington, under the direction of Prof. J. R. Eastman, for the year 1901, has been recently received. As in former years, it contains the details of all the observations which are made every three hours during each day. These include the corrected readings of the barometer, and of the wet and dry bulb thermometers, the symbols indicating the character of the clouds, the estimated amount of cloudiness, wind direction and velocity, together with the daily means. The six tables which follow record the results, such as the maximum and minimum temperatures for each month, daily and monthly means of the corrected barometric readings, &c. The volume contains also the meteorological observations made at the same hours at the new naval observatory with a view to determine the difference of the thermometric conditions at the two localities, in order that future records at the new observatory can be properly compared with the records at the old observatory, which extend from 1845 to 1892 inclusive.

WE have received from the editors of the *Photogram* a new edition of a set of cards which are intended for the pocket-book of the photographer. These cards, 5×3 inches in size, contain a great amount of very useful information, some of which the

practical photographer is sure to find serviceable either in his studio or out in the field. Thus we have a brief guide for correct exposure for various kinds of plates and light, tables of enlargement and reduction for telescopic lenses, how to find south without a compass in order to fix the time of best lighting, the metric and British systems of weights and measures and their connection one with the other, photographic temperatures and a comparison of different thermometer scales, &c. These cards, eight in number, can be obtained from the office of the *Photogram* by forwarding one penny stamp, and they are valuable and useful for the money.

THE theory of the dimensions of units in the electrostatic and electromagnetic systems has on various occasions been criticised. A short note dealing critically with dimensions of physical units in general is given by Dr. Ladislaus Gorczyński in the *Physikalische Zeitschrift*, iv. 5. In thermodynamics, the author points out that the dimensions of temperature should not be omitted from the expressions for the dimensions of such quantities as thermal conductivity, specific heat and entropy, and he introduces the dimensions of K and μ into the electrical systems. Herr Gorczyński supports the position assumed by Schreber and disagrees with certain views expressed by Hesehus. In particular, he considers that the assumption of a relation of the form $v = \sqrt{e/d}$ connecting the "v" of electromagnetism with elasticity and density is unjustifiable. The general conclusion is that the conventional treatment of dimensions of units is unsatisfactory, and that it is not at present possible satisfactorily to express the dimensions of all physical units in terms of those of the three fundamental units of length, time and mass alone. It is certainly safer to introduce too many fundamental units the dimensions of which are treated as independent of one another than to cut down the number by regarding the measure of any physical quality as a dimensionless number.

THE first report on a chemical and physical study of the soils of Kent and Surrey has been issued by the South-eastern Agricultural College, at Wye, by Mr. A. D. Hall and Mr. F. J. Plymen (1902). The object is eventually to accumulate such a series of analyses of the soils, chemical and mechanical, as will enable the College, when given the situation of any field, to indicate in a general way the kind of manures wanted for each particular crop. The two counties are not much covered with drift deposits, and these are depicted on the one-inch Geological Survey map, but the pressing need of a geological map on the six-inch scale is pointed out. The present report deals only with the soils resting upon the London Clay, Chalk and Gault. By procuring samples of soils from each geological formation in a number of localities, a good general knowledge of them has been obtained. Particulars of these, with methods of analyses, are given. With regard to the Gault soils, it is remarked that the most profitable use to make of them "is to keep them or lay them down as permanent pasture." On both London Clay and Chalk there is considerable variety of soil, and recommendations are made on the cultivation of different areas.

A SECOND edition of Dr. A. J. Ewart's "First Stage Botany" has been published by Mr. W. B. Clive. Several additions and alterations have been made.

THE second volume of Prof. Wundt's "Grundzüge der physiologischen Psychologie" has been received from Mr. W. Engelmann, Leipzig. The first volume was noticed a short time ago (November 6, 1902, p. 2), and an estimate of the value of this great work can be obtained from that review. After the work has been completed, a notice of the new volumes will appear.

THE three essays which were successful in the recent competition for the erection of a sanatorium for tuberculosis, initiated by His Majesty the King, are reprinted in full in the current number of the *Lancet*, with reproductions of the plans of the buildings. The essays are valuable epitomes of modern knowledge of the cause, prevention and cure of tuberculosis.

WE have received from Messrs. Isenthal and Co. their latest catalogue and price list of apparatus for radiography and general electro-medical work. The list is a very complete one and shows that the firm is in a position to supply all the apparatus needed in this class of work, from single pieces of the simplest type to full sets made up into suitable cabinets. We note also that the firm arranges for courses of lessons in the use of the apparatus for those who desire it.

THE "Annuaire du Bureau des Longitudes" for 1903 has been published by M. Gauthier-Villars, Paris. This compact little volume contains, as usual, a mass of information indispensable both to the man of science and to the engineer. Among the contents of the volume may be specially mentioned the contribution by M. R. Radau, on shooting stars and comets, and that by M. J. Janssen, on science and poetry. The discourses delivered at the funerals of MM. Cornu and Faye are also included in this year's issue of the annual.

THREE new volumes of the first annual issue of the International Catalogue of Scientific Literature have been received, and are similar in character to those already described. The subjects of the volumes are physics (part i.), meteorology (including terrestrial magnetism) and mechanics. The second part of the catalogue of physical papers will shortly be published and will complete the volume on physics. The two volumes on meteorology and mechanics are each complete in themselves, and the portions of the scientific literature of 1901 not included in them will form a part of the second annual issue of the Catalogue.

MR. W. ENGELMANN, Leipzig, has issued two new volumes in Ostwald's series of scientific classics. As is well known, each volume in this series contains one or more papers which have influenced the progress of science, selected from the works of investigators of various nationalities and translated into German when written in other languages One of the volumes recently published contains series xiv. and xv. of Faraday's experimental investigations in electricity, translated from the *Philosophical Transactions* of 1838 and edited by Dr. A. J. von Oettingen; the other volume (No. 132) contains a translation of two papers by Andrews, on the continuity of the gaseous and liquid states of matter, from the *Phil. Trans.* of 1869 and 1876, edited by Dr. Arthur von Oettingen and Prof. K. Tsuruta.

WE have before us the forty-second yearly issue of the *British Journal of Photography*, edited by Mr. Thomas Bedding (Henry Greenwood and Co., Strand), and a glance at this bulky volume, which contains nearly 1600 pages, of which about 600 are text matter, is sufficient to indicate its vigorous and healthy condition. The book is arranged on similar lines to those of its predecessors, and will be found a mine of interesting, practical and useful information on photographic topics. Among some of the contents may be mentioned a very complete list of the officers of photographic societies in the United Kingdom, America and on the continent, a large collection of photographic formulæ and recipes in both the English and metric systems, chapters on photomicrography with bibliography by the editor, a summary of the recent novelties in apparatus, &c., since the publication of the last almanac, practical notes and suggestions of the year, and an epitome of the year's progress, in which is given a *résumé* of the more important discoveries and improvements. Scattered

among the text are some excellent reproductions illustrating the behaviour of different lenses and speeds of shutters, and the frontispiece is a contact print on Barnet platino mat bromide paper. The low price of the volume (one shilling) and the useful nature of the contents should render it indispensable to every photographer.

IN the current number of the *Comptes rendus* is a note by Prof. Henri Moissan on a new method of preparing the silicon analogue of ethane, Si_2H_6. This substance was originally obtained by the author, in conjunction with Dr. Smiles, by the partial condensation at -200° C. of an impure silicon hydride prepared by the action of hydrochloric acid upon a silicide of magnesium of undefined composition. Attempts to prepare the same compound from the lithium silicide, Li_2Si_6, by the action of dry hydrogen chloride or a dilute solution of hydrochloric acid were unsuccessful, hydrogen being the only gaseous product. It has now been found that by the gradual addition of lithium silicide to concentrated aqueous hydrochloric acid, the silico-ethane is readily formed in abundance and can be separated by means of cooling to the temperature of liquid air.

THE same number contains an account, by M. F. Bodroux, of another application of the organo-magnesium compounds to organic synthesis. It has been found that if a magnesium alkyl chloride or bromide, prepared in the usual way by the action of magnesium upon an ethereal solution of the alkyl bromide or chloride, is treated with iodine, the alkyl iodide is produced in nearly quantitative yield, together with magnesium iodochloride or bromide. Propyl bromide and isoamyl chloride treated in this way have furnished about 80 per cent. of the theoretical quantities of the corresponding iodides. The reaction is equally applicable to aromatic derivatives, and will simplify greatly the preparation of many monoiodo-derivatives of benzene.

THE much-discussed question of the chemical character of bleaching powder is revived in a recent number of the *Zeitschrift für anorganische Chemie*, which contains a long paper on the subject by Herr Winteler, of Darmstadt. The investigation appears to have arisen from a difficulty which was experienced in making good bleaching powder from electrolytic chlorine, owing to the gas containing considerable quantities of carbon dioxide. The chief conclusions reached by Herr Winteler are as follows. Dry chlorine does not act on dry calcium hydroxide, but in the presence of moisture chlorine water is first formed. This contains hypochlorous and hydrochloric acids, which then act upon the calcium hydroxide. The action involves complicated equilibria, which depend on the temperature, the amount of water present, the rate at which the chorine is passed, &c. Bleaching powder possesses no definite formula, but is a mixture of bodies resulting from the balanced reactions just referred to. It contains basic calcium chloride and basic hypochlorite as normal components, and may contain chloride and hypochlorite as well as hydroxide and the free acids. The decomposition of bleaching powder into chloride and oxygen takes place when there is an excess of hydroxyl ions; on the other hand, an excess of hydrogen ions leads to a decomposition into chlorate and chloride. Working upon this theory of the character of bleaching powder, Herr Winteler shows how it is possible to prepare a good product even when using unpurified chlorine containing 6 per cent. of carbon dioxide.

THE additions to the Zoological Society's Gardens during the past week include a Fennec Fox (*Canis cerdo*) from North Africa, presented by Dixon Bey; two Common Marmosets (*Hapale jacchus*) from South-east Brazil, presented by Mr. J. B. Joel; two Egyptian Jerboas (*Dipus aegyptius*) from North Africa, presented by Miss Chesterman; two Eastern One-wattled Cassowaries (*Casuarius aurantiacus*) from New Guinea; a Blossom-headed Parrakeet (*Palaeornis cyanocephalus*) from India; a Gangetic Trionyx (*Trionyx gangeticus*) from India, deposited.

OUR ASTRONOMICAL COLUMN.

COMET 1902 *d*.—From observations made at Hamburg on December 3 and 11, and at Paris on December 22, Herr Ebell has calculated the following elements and ephemeris for this comet:—

T = 1903 March 23·544 Berlin M.T.

$$\left.\begin{array}{rl} \omega = & 5^\circ\ 43'\ 32''\cdot6 \\ \Omega = & 117\ \ 29\ \ 51\cdot2 \\ i = & 43\ \ 54\ \ 17\cdot4 \end{array}\right\} 1903\cdot0$$

$$\log q = 0\cdot443876$$

Ephemeris 12h. M.T. Berlin.

1903		α h. m. s.		δ ° ′		log Δ		Brightness.
Jan. 0	...	7 3 10	...	+3 47·3	...	0·2925	...	1·4
4	...	7 0 19	...	+4 54·1	...	0·2880	...	1·4
8	...	6 57 23	...	+6 4 6	...	0·2847	...	1·5
12	...	6 54 27	...	+7 18·2	...	0·2825	...	1·5
16	...	6 51 34	...	+8 34·4	...	0·2816	...	1·5
20	...	6 48 47	...	+9 52 6	...	0·2818	...	1·5

Unit brightness at time of discovery.

On December 22d. 10h. 44m.·3 Paris M.T., the comet was observed in the following position by M. Bigourdan at Paris:—
α (apparent) = 7h. 9m. 7s.·4, δ (apparent) = + 1° 32′ 55″.

M. Fayet has found that this comet has the greatest perihelion distance recorded for any comet since that of 1729.

OBSERVATIONS OF VARIABLE STARS.—In No. 3837 of the *Astronomische Nachrichten*, M. M. Luizet, of the Lyons Observatory, publishes his observations of five variable stars and gives his results for each star in a tabular form.

The result of 285 observations of Algol, made between November 18, 1897, and March 12, 1902, indicates a possible slight negative correction to the elements published by Mr. Chandler in No. 509 of the *Astronomical Journal*.

One hundred and fifty-seven comparisons of the irregular variable ε Aurigæ indicate great irregularities in the brightness of this star, which on December 10, 1901, was actually one or two degrees fainter than ν Persei.

One hundred and fourteen comparisons of W Orionis were made between October 26, 1898, and March 19, 1902, and these show that both the duration of the period and the magnitudes at maxima and minima vary greatly. The following elements show the closest agreement to the observations:—

$$\left.\begin{array}{l} \text{Maximum 1899 February 22} \\ \text{Minimum 1899 March 10} \end{array}\right\} + 32\text{d.}\cdot 32\ \text{E.},$$

but there are several observations which are not reconcilable to this period.

Observations of T Monocerotis and ζ Geminorum have also been made, and tables of their maxima and minima are given by M. Luizet.

THE SPECTRUM OF ε AURIGÆ.—From the investigation and measurement of spectrograms obtained during 1901 and 1902 by Prof. Hartmann and Dr. Eberhard, Prof. H. C. Vogel has found that ε Aurigæ is a spectroscopic binary which has a very long period.

The spectrograms referred to show that the hydrogen lines in the violet region, beyond H and K, stand out with exceptional prominence in this star, and a close investigation as to the cause has led to the conclusion that the spectra of two stars—one of the α Cygni type, the other lying between the limits of Types I. and II. (α Persei, γ Cygni)—are present, the one being exactly superimposed on the other.

OBSERVATIONS WITH A BINOCULAR TELESCOPE.—In *Popular Astronomy*, No. 100, Mr. D. W. Edgecomb describes the performances of the 6¼-inch binocular telescope, made by Messrs. Alvan Clark and Sons.

In describing the features of the Moon, Jupiter and Saturn as seen with the binocular, the writer states that the objects

present more detail, are brighter, and appear larger than when seen through an ordinary single telescope of the same aperture. In addition to this, the "seeing" is much steadier, and the stereoscopic effect obtained greatly enhances the beauty of the objects observed.

Such objects as Clark's companion to γ Lyræ, the companion to τ Orionis and the Mitchell companion to Rigel have all been steadily observed, and it is generally considered necessary to use an instrument of 7 or 8 inches aperture in order to see the last-named object.

The prisms used in this instrument are $2\frac{7}{8}$ inches long and $1\frac{3}{16}$ inches thick, the rays from the objectives traversing $5\frac{1}{2}$ inches of glass before reaching the eyepieces.

RECENT AMERICAN BOTANY.

MR. M. L. FERNALD[1] has published a very interesting review of the birches belonging to the groups *Betula alba* and *B. nana*. These trees and shrubs inhabit the northern regions of both hemispheres, and Mr. Fernald recognises in America seven species and seven varieties, of which six species and five varieties are common to the Old World. Thus, contrary to the opinion of some recent authors, the American white birches are mostly non-endemic, though exhibiting numerous apparently distinct forms. Not only is this true, but the admitted species intergrade all along the line. "It is quite possible to trace by a series of specimens a direct connection between the dwarf *Betula nana* or *B. glandulosa* and the tall *B. alba*. . . . But since it is obviously impracticable to regard all these forms as one species, it seems wiser to recognise the more marked centres of variation as species which are admitted to pass by exceptional tendencies to other forms ordinarily distinguished by marked characteristics" (p. 189). This, of course, brings up the question of the definition of species. The present writer has been accustomed to use the accompanying diagram in teaching biology. The line *a a* represents a species which is slightly dimorphic, as is indicated by the two prominences. The line *b b* represents a strongly dimorphic species, connected (at *b'*) by very few intermediates. The line *c c* represents a case in which the intermediates have died out, and there is a complete break (at *c'*) resulting in the formation of two species. It is now to be pointed out that this break must be spacial or geographical, and not merely morphological, otherwise the two sexes of the same species would often have to be regarded as distinct species. Such a break need not be geographical in the ordinary sense, but when the two species inhabit what is nominally the same locality, they are found to be differently related to their environment, or related to different closely adjacent environments. Furthermore, they must breed true, and not ordinarily interbreed one with another.

This sounds simple enough, but the application of these principles is not so simple. In the diagram, the case of *b b* is obviously more like that of *c c* than it is like that of *a a*. The difference between a slight break and a slight connection is infinitesimally small, yet after all it is a real difference—something existing in Nature, and not subject to individual opinion. If this criterion is admitted, because of its capability of exact definition, then the whole series of birches discussed by Mr. Fernald must apparently be regarded as one species!

Another sort of case is offered by the plants of the Galapagos Islands, recently reviewed in a most valuable memoir by Dr. B. L. Robinson.[2] *Euphorbia viminea*, J. D. Hooker, has eight distinct forms confined to as many islands (one only being found on two). These plants are readily distinguishable, but their characters are such as would be ordinarily of no value for distinguishing species in the genus. On continental areas, similar species of Euphorbia are polymorphic, with innumerable similar variations connected by every sort of intermediate. Consequently, Dr. Robinson does not treat the Galapagos plants as separate species, or (with one exception) even as varieties, but as "forms." Now, according to the above definition of species, these plants are perfectly good species, for the breaks in continuity, slight as they are, appear to be absolute.

There is, perhaps, one way of escaping from this conclusion. Distinct species should not promiscuously interbreed; there should be some sort of "physiological" barrier. It is known, in the case of the ostensibly distinct species of Lavatera from the islands off the coast of California, that this barrier does not exist. Perhaps, if the different Galapagos Islands' forms of *Euphorbia viminea* were grown together, they would completely fuse and give a single promiscuously varying type like those of the continents. But, after all, the question is what they actually do, not what they might do, under hypothetical conditions. The answer to this question must be that they remain distinct.

It seems to the present writer that the only precise criterion of species must be a spacial one, just as the only reason for species is that of function, or the relation between the nature of the creature and the place it occupies. But, admitting this on philosophical grounds, we are forced to recognise species of every degree of distinctness, just as the geographer recognises islands separated by every sort of distance from the mainland. It is easier, no doubt, to accept instead the morphological criterion, and this is actually what we have to do in taxonomic work,[1] for lack of evidence of the other kind; but this leaves the whole matter to be decided by individual opinions, with results known too well.

It is probable, if not certain, that variable plants on continental areas produce many "temporary species." That is to say, local colonies become more or less differentiated and remain so until swamped by invasions of the parent form or some other variety. Whether we recognise these "temporary species" depends, in practice, upon the degree of difference exhibited. Not rarely, the distinctions are constant and marked over a certain area, but the very same distinctions elsewhere occur as individual variations in the midst of the parent species. I have recorded such cases in the genera Sphæralcea and Cleome.

At the close of his work on the Galapagos flora, Dr. Robinson presents a most lucid and philosophical discussion of the whole subject; it is so full of fact and thought that a brief summary could not do it justice. In particular, attention must be called

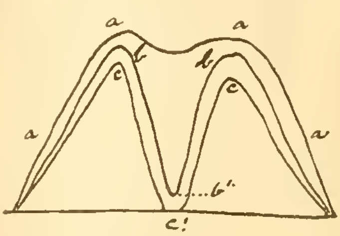

FIG. 1.

to his statement of the reasons why the local insular varieties persist in spite of the occasional infusion of new blood.

Mr. Carl Purdy's revision of the genus Calochortus[2] is another work of great interest. These beautiful "butterfly lilies" are extremely abundant in the Pacific region of North America, and are almost indefinitely variable. The variations are of all sorts, sometimes "constitutional" rather than morphological. Says Mr. Purdy, "In cultivation it has frequently been found that a very slight variability in strains is accompanied by a marked constitutional difference. In two beds of *Calochortus venustus*, planted in the same soil and separated only by a thin board, it would puzzle a botanist to state wherein the plants vary. They come from widely separated localities, and the difference is one more easily detected by the eye than conveyed by words. In one bed, two-thirds of the leaves are already destroyed by mildew (Botrytis), while in the other, not one leaf is injured; and such is the case whenever and wherever the two are planted" (p. 108). Mr. Purdy points out that in some localities the plants are very uniform, while in others they are extremely variable, with hundreds of distinguishable phases. It is probable that the phenomenon of "temporary species" is common in this genus, and the union of such morphologically, but not physiologically, distinct types is the cause of much variability. At the same time, there are species which always remain distinct, never producing fertile hybrids. That Mr. Purdy has tested so many of the forms for such "physiological barriers" gives his work especial value and importance. It does

[2] *Proc.* Amer. Acad., October, 1902 (vol. xxxviii.).

[1] De Vries has assumed that, because botanists so distinguish species (admittedly of necessity), therefore the morphological criterion is the genuine one. Thus species have no better foundation in Nature than genera, which are wholly based on reasons of convenience.

[2] *Proc.* Calif. Acad. Sci., 3rd series, Botany, vol. ii. No. 4 (1901).

not appear that mere isolation suffices to produce even distinct varieties of Calochortus. For instance, *C. catalinae*, Watson, is found on Catalina and other islands, and also on the mainland; but instead of running into numerous insular races, it "is one of the least variable" of all, and no variety has been distinguished by name. On p. 141, Mr. Purdy admits that his *Calochortus venustus*, var. *eldorado*, "var. nov.," is the same as *C. venustus purpurascens*, Watson; while he applies the name *purpurascens* (Purdy, 1895) to a quite different variety of the coast range. This surely cannot be permitted; the former must stand as *purpurascens*, while the latter may be called var. *Caroli*.

EARTHQUAKE OBSERVATIONS IN GALICIA.

THE ninth number in the new series of the publications of the Austrian Academy of Sciences relates to earthquakes observed during the year 1901 in Lemberg. The first feature which one observes in this publication, the author of which is Dr. W. Láska, is that he describes each earthquake according to the phases it exhibits, the various phases being distinguished from each other by differences in their periods. Twenty years ago, earthquakes were described as consisting of preliminary tremors, shocks and concluding vibrations, each of which had distinguishing periodic motions. Now we find first preliminary tremors of types p_1' and p_1'', second preliminary tremors of types p_2', p_2'', p_2''' and p_2'''', and on they go, commencing with p_1', with periods between 2·1 and 6·9 seconds, and ending with types where the periods have exceeded one minute. Inasmuch as these groups overlap, so that it is frequently difficult to assign a set of waves to their proper group, for our own part we are for the present content to divide the seismic spectrum into four parts—first and second preliminary tremors, large waves and concluding vibrations. In addition to these entries, Dr. Láska gives tables of tri-daily readings of two levels and of a thermometer. The most interesting portion of the work is, however, found in its introduction, where, amongst other matters, reference is made to the natural period of a pendulum as influencing the magnitude of its records and to rules which enable an observer to determine the distance of an origin from the inspection of a seismogram.

One simple rule is to diminish the duration of the first preliminary tremors reckoned in minutes by unity and multiply the same by 1000. The result is an approximation to the distance of the origin expressed in kilometres. For example, if a seismogram shows that the preliminary tremors had a duration of 7·6 minutes, then the earthquake it represents originated at some place about 6600 kilometres distant. The mnemonic is certainly simple, but its application is confined to those records where preliminary tremors are well defined. These are comparatively few in number and the accuracy of the determination is dependent upon the measurement of intervals of time which are small. These objections apply to a second rule suggested by Dr. Láska, the value of which is apparently still further impaired by the introduction of two assumed constants determined by Dr. F. Ōmori. These constants are the velocities of the first and second preliminary tremors as determined from observations of ten earthquakes which originated near Japan and were recorded at Tokio and in Italy.[1] To obtain these velocities, the arcual distance between the Tokio isoseist and Italy is divided by the difference between the times of observation in Tokio and Italy. Had the distance between the origins and Italy been divided by the difference of times between the times of origin (which are easily calculable) and the times of arrival in Italy, then the constants given by Dr. Ōmori would have been reduced. A further reduction would be made on the assumption that the wave paths of the motion considered had approximated to chords. If the speed of the preliminary tremors between their origin to the Tokio isoseist had been the same as it was from that isoseist to Italy, then the above objections might be withdrawn, but this, according to Dr. Ōmori's own showing, appears hardly to be the case.[2]

Although it is interesting to find the relationship between the duration of preliminary tremors and the distance they have travelled again brought to our notice, the well-known method of determining origins by the interval of time between the first motion of an earthquake and the subsequent arrival of the large waves is apparently one of more frequent and certain application.[1]

PILOT CHARTS OF THE METEOROLOGICAL OFFICE.

IN addition to the usual information, the Meteorological Office pilot chart of the North Atlantic and Mediterranean for the month of January deals with some new features, necessitating the use of the back of the chart as well as the front. There is an account of the destructive cyclone which visited our coasts on October 15–16 last, and also of the slow-moving disturbance and its accompanying gales which wandered about the Tyrrhenian Sea from October 22–29. A summary is given of the characteristics of the surface temperature of the Atlantic for each of the ten months from January to October last, the most striking feature being the evidence of a distinct tendency for the water in the immediate vicinity of western Europe to remain cooler than the normal during the first nine months, a fact which may be associated with the persistent low air temperature over the adjacent land during the spring and summer. On the Newfoundland banks, there was a marked excess of warmth through the first six months, little or no ice being found in the locality. In October, an excess was shown on the eastern side of the ocean for the first time, and simultaneously the air temperature over the British Isles passed above the average in all districts. With the object of discovering what connection, if any, there is between the movements of weather systems and the distribution of the temperature of the surface water, observations are being collected for obtaining the mean barometric pressure month by month over the region from 30° to 60° N., 0° to 70° W., and the tracks of the centres of storm areas. For October, the mean isobars are superimposed on the sea temperature results, while the storm tracks are given on a separate chart.

To arrive at any definite conclusion as to cause and effect, it will require a long series of such charts—probably, too, for shorter periods than a calendar month, periods determined by the prevailing type of conditions, depending mainly on the positions and stability of the controlling anticyclones. Summaries are given of the ice reports from the whaling steamer *Balaena*, up Davis Strait, and the barque *Lady Head*, in Hudson Bay, last summer. Neither vessel passed any ice in the lower part of Davis Strait when heading for home in October. On July 1 last, the New Zealand Shipping Company's s.s. *Waikato* was disabled in 33° S., 6° E., and for twenty-six days she drifted helplessly about the south Atlantic, being finally taken in tow on July 27 in 28° S., 13° E., having in the interval travelled 812 miles, or at an average rate of more than thirty-one miles per day. The track of her wanderings day by day, together with the direction and force of the wind, supplied by Captain Kiddle, is reproduced, with the addition of the normal current circulation of the region, which shows that the *Waikato* followed closely the drift indicated by the Admiralty chart.

STARVING A PARASITE.

IN a recent paper read before the Royal Society,[2] Prof. Marshall Ward described the results of three series of experimental cultures of Brome-seedlings in sand, to which had been added various nutritive salts, or manurial mixtures, which were then infected with the parasite to see how the latter behaved on starved seedlings. Some of the seedlings received all the salts necessary for successful development, others none of such salts other than the root-hairs could extract from the sand itself and from the reserves in the endosperm, and others all necessary minerals except phosphorus, or potassium, or magnesium, or calcium, or nitrogen respectively.

So far as the seedlings themselves are concerned, the effects of the mineral starvation were most evident in the small stature,

[2] "Experiments on the Effect of Mineral Starvation on the Parasitism of the Uredine Fungus, *Puccinia dispersa*, on Species of Bromus." By Prof. H. Marshall Ward, F.R.S. Read before the Royal Society on November 27.

reduced root-system, narrow leaves, pale colour, &c., the nitrogen-starved and phosphorus-starved specimens, and in those lacking all salts.

In no case, however treated were the starved or manured seedlings rendered immune. All were successfully infected by normal uredospores adapted to the normal species, though in the phosphorus-free and in the nitrogen-free seedlings, and in those deprived of all salts, there were signs of retardation of the infection, and the resulting patches and pustules of fungus spores (uredospores) were fewer and smaller.

As regards the fungus, apart from the reduced size of the mycelium, as expressed in the small pustules and retardation of development above referred to, even the reduced number of spores borne on the smallest pustules—*e.g.* on phosphorus-starved plants—showed no signs of morphological degeneration, or of diminished germinating capacity or virulence—*i.e.* capacity for infection.

The positive results, therefore, are purely *quantitative*. A starved plant develops smaller pustules and fewer spores, simply because it can offer smaller quantities of food materials to the mycelium in its tissues; these food-materials, however, are as good in *quality* as they are in the case of a normal or highly manured plant. Not only so: the experiments also show that spores developed on starved seedlings can also infect seedlings which have been *similarly starved*—for instance, the few spores obtained from the very minute pustules of a phosphorus-starved seedling *can infect another phosphorus-starved seedling* just as readily as they can a normal plant, and so on through the series.

Consequently, we must infer that predisposition and immunity on the part of the Brome, and impotence and virulence on the part of the Fungus, are alike independent of mere nutrition; and since the author has shown in previous papers[1] that these properties are also independent of the anatomical structure of the host-plant, it must be concluded that the phenomena of adaptive parasitism depend on deep-seated peculiarities of the living protoplasm of the cells—possibly their capacity for forming enzymes, toxins and antitoxins, chemotactic bodies and the like, although such bodies have as yet resisted all efforts at extraction.

The full paper is illustrated with photographs and tables.

THE NORTH OF ENGLAND SCIENCE CONFERENCE.

THE first annual conference of persons in the north of England concerned in primary, secondary, technical and other forms of higher education, was held at Manchester on January 2 and 3, and proved highly successful. The conference may be regarded as a natural outcome of similar meetings which have for some years past been held annually in London under the auspices of the London Technical Education Board. Many teachers and other educationists from the north of England have, year by year, attended the conferences in London and have become familiar with the benefits to be derived from a discussion of educational methods. Believing that many teachers and others in the northern counties, anxious to reap the advantages springing from such meetings, were debarred from attendance by the expense of travelling, a number of prominent educationists in Lancashire and Yorkshire arranged this series of meetings in Manchester, and the phenomenally large attendance at all the discussions has fully justified their enterprise. More than three thousand persons accepted invitations to be present, and every meeting was characterised by the greatest enthusiasm. It had been intended to hold all the meetings at the Manchester Municipal School of Technology, but the number of visitors to be accommodated necessitated the duplication of meetings, and a few days before the commencement of the conference arrangements were made for additional papers to be read in other places at the same time as those originally provided.

In addition to the papers and discussions, the executive committee provided exhibitions to illustrate methods of nature-study, the teaching of experimental science, school furniture and other forms of school equipment. Demonstrations on the teaching of light and magnetism were respectively given by Messrs. Adamson and Moore, of the Manchester Technical School; and, in addition, the numerous excellent educational institutions in different parts of the city were thrown open for the inspection of visitors. A conversazione, held at the School of Technology on the evening of the first day of the conference, provided a good opportunity for teachers in different districts to become acquainted.

The method of conducting the meetings deserves to be more widely imitated in educational conferences. Immediately after the reading of a paper, the discussion of the subject was opened by one or two speakers of wide experience, who had been previously selected for the purpose and had prepared their remarks, with the result that the discussion was much more helpful to teachers than is usually the case on similar occasions. Moreover, as printed copies of the papers for discussion could be obtained immediately before the commencement of the meetings, subsequent speakers were able to contribute something of value to the debate, and general remarks having little relation to the subject in hand were reduced to a minimum. Messrs. J. H. Reynolds and H. Lloyd Snape, the honorary secretaries, are to be congratulated upon the complete success of the conference.

Half an hour before the commencement of the serious business of the conference, the visitors were welcomed by the Lord Mayor of Manchester, and his remarks were warmly endorsed by Dr. Maclure, Dean of Manchester, by Prof. Hopkinson, principal of Owens College, and by other prominent educational authorities of the district.

School Curricula.

Mr. M. E. Sadler presided at the first meeting of the conference, and in his introductory speech dealt with the aims of education. The purpose of all practical inquiry and experiment was, he said, to find the kind of training which would best equip the rising generation for their life as home-makers or wealth-makers, under the actual conditions of the modern world. The reform of the curricula of our schools would, he thought, involve certain practical changes in the conditions under which many English teachers at present worked. Little boys ought not to be prematurely specialised in classical erudition in order to win scholarships at the public schools. In no school should any pupil fail to gain insight into the meaning of scientific method and into the operation of physical laws. In any type of curriculum, drawing and other forms of expression by means of the hand should be given a permanent place and should be worked in, as far as possible, in connection with the other subjects of study. There was a need that scientific and experimental study of education should be actively carried on at the universities, with encouragement of similar investigation among teachers already at work in the schools.

Miss Burstall, head mistress of the Manchester High School for Girls, then read a paper on the curriculum in different types of schools, in which she endeavoured to find general principles by which school curricula may be tested and, if necessary, amended. Three principles were deduced; first, the gradual adjustment of the child to the spiritual possessions of the race; second, that of training; and third, the theorem that the order of subjects in school life is conditioned by the laws of development of the child. These principles, Miss Burstall contended, lead to a broad rather than a narrow curriculum. The compulsory subjects of the curriculum for all children could be divided into three groups—English, including literature, history and geography, the humanities; science, *i.e.* arithmetic and nature-study for young children, mathematics and science later; physical and manual training. Technical education should be reserved for the last year of school life, when the specialised study of mathematics and science required for engineering, or housewifery and the domestic arts for girls, might be taken up. The subsequent discussion was very animated, and many teachers took part in it. Mr. King, high master of the Manchester Grammar School, contended that the subjects of education did not so much matter as the method in which they were taught. Prof. Armstrong, F.R.S., deprecated a statement of Miss Burstall's that a child's reasoning powers developed late.

A paper by Mr. W. E. Hoyle, of the Manchester Museum, on the value of natural history collections for teaching purposes, was also read at Owens College during the first morning of the conference.

[1] *Proc.* Cambridge Philos. Soc., vol. xi. 1902, pp. 307–328; and *Annals of Botany*, vol. xvi. 1902, pp. 233–315.

Coordination of Science Teaching.

Prof. Armstrong, F.R.S., took the chair at the afternoon meeting, when Dr. Kimmins read a paper on the coordination and delimitation of science teaching in various grades of schools. He maintained that the aim of rational methods of teaching science was not the acquisition of knowledge, but rather the training of the intelligence of the child and the development of certain mental qualities of the highest value. Useful knowledge had been and was still the curse of science teaching. He urged that the adoption of rational methods in science teaching simplified to a remarkable degree the relation and delimitations of such teaching, and instanced the coordination in workshop and laboratory instruction which has been so effectually secured in London schools. In the discussion which followed, Dr. Forsyth emphasised the need of a sound general education for all students who intended later to enter technical colleges.

During the afternoon, Canon Rawnsley read a paper at the Central Higher Grade School on the national import of co-education.

Elementary Experimental Science.

Prof. Smithells occupied the chair at the third meeting, when papers were read by Mr. French, on the teaching of experimental physics in its early stages, and by Mr. R. L. Taylor, on the similar teaching of experimental chemistry. Mr. French described and approved the methods of teaching elementary physics advocated by the British Association committee and now very generally adopted in secondary schools. Mr. Taylor attacked, in a friendly way, the heuristic method of teaching chemistry as advocated by Prof. Armstrong, an admirable method which, he said, had become an undesirable system. A lively debate ensued, in which many speakers, following Mr. Taylor's lead, appeared to strive to accentuate the abuses of the "research" method of teaching chemistry rather than to recognise its many advantages

Prof. Armstrong, in replying to Mr. Taylor's criticisms, said the question at issue was not merely a difference of opinion. There was a great principle at stake, and that principle was—Were they or were they not to train boys and girls at school to think for themselves, to reason for themselves, to do for themselves, to be thoughtful, observant human beings throughout the time they were at school, whenever they left school, and ever afterwards? The majority of the subjects that were taught and had been taught up to the present day had been taught in an academic, didactic and unpractical way. Britain was what it was because of the individuality of Britishers. Our modern school system was sapping our individuality. It was with the object of avoiding that loss of character that he and others were bringing practical methods into vogue.

Prof Smithells, in a very able speech, summarised the discussion, and traced many of the improvements in the teaching of science in England during the last ten years to the advocacy by Prof. Armstrong of rational methods of teaching, but at the same time pointed out there were extravagances in some of Prof. Armstrong's utterances which were, perhaps, inseparable from the work of a pioneer.

At the Central Higher Grade School during the discussion on the heuristic method, Mr. Lomas read a paper on fitting up school laboratories.

The Teaching of Nature-Study.

The concluding meeting of the conference was presided over by Prof. Miall, F.R.S. A paper was read by Mr. H. Wager on the methods of nature-study, in which he urged that nature-study in its widest aspects should be regarded as the study of elementary natural science, and should include, in addition to the simple facts of botany, zoology and geology, so much of elementary physics and chemistry as was concerned with the study of air and water, the condensation of moisture, frost, snow, and other simple natural phenomena. The formal study of any branch of science was not implied in it, nor was it desirable, in the earlier stages, at any rate, that they should be restricted to one branch of science only. The main objects in advocating the inclusion of nature-study in schools were (1) to arouse an interest in natural objects and phenomena, and (2) to develop to some extent the scientific method of dealing with simple problems, by the careful observation and comparison of facts and drawing inferences from them.

Prof. Weiss afterwards suggested that some portion of public parks should be made available for nature-study. He disagreed with Mr. Wager, who had deprecated the employment of diagrams and museums, and said he could not but think that there were many objects from which lessons could usefully be learnt without having the living animal before them. They should first go to the living objects, but useful illustrations could be drawn from other countries, and where they had opportunities they should use them.

During the concluding afternoon, Mr. W. C. Fletcher, of Liverpool Institute, read a paper on the teaching of geometry, in which he generally supported the recommendations of the British Association committee.

The next conference will be held at Leeds.

A. T. S.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE annual meeting of the Association of Science Masters in Public Schools will be held at the University of London on January 17.

WE learn from the *Times* that the Treasury has given its assent to the scheme by which Reading Corporation acquires the site and buildings of the University College at a cost of 50,000*l*. The college, in exchange, obtains a much larger site on the London Road, whereon it is intended to erect a handsome pile of college buildings.

FROM a letter which Sir Michael Foster has addressed to Sir John Rotton, it appears that an election of a new member for the University of London may not be necessary. This news will be received with great satisfaction by most of the electors, for the University has in Sir Michael Foster a representative of the high intellectual standard demanded of an academic constituency. Since expressing the wish to resign his seat, the circumstances which suggested that course have, most fortunately, changed, and he now desires to know whether the graduates wish him to remain their member or not.

CANDIDATES for the Andrew Carnegie research scholarships to be awarded by the Iron and Steel Institute must send in their applications, on a special form, before the end of February to the Secretary of the Institute, 28 Victoria Street, S.W. The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students, who have passed through a college curriculum or have been trained in industrial establishments, to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. There is no restriction as to the place of research which may be selected, whether university, technical school or works, provided it be properly equipped for the prosecution of metallurgical investigations. Last year the Andrew Carnegie gold medal was awarded to Dr J. A. Mathews, New York, and scholarships, each of the value of 100*l*., were awarded to O. Boudouard, Paris; W. Campbell, New York; A. Campion, Coopers Hill; P. Longmuir, Manchester; E. Schott, Berlin; and F. H. Wigham, Wakefield.

PROF. ROBERTSON, the Canadian Commissioner of Agriculture and Dairying, recently made a visit of investigation and observation to a portion of the State of Ohio, where remarkable progress has been made in the improvement of rural schools by the plan known as that of consolidation. Instead of having a great number of small school districts, each with its own little school, these districts are united in one, and a large central school meets the needs of the whole area. The children are conveyed to and from the central school by means of vans at the expense of the rates. Prof. Robertson sums up some of the advantages afforded by the consolidation of rural schools and the free transportation of pupils. It results in the attendance of a larger number of the children in the locality, it brings about a more regular attendance of pupils of all grades of advancement, it ensures teachers of higher qualifications and longer experience in rural schools, it creates conditions for a proper classification of pupils and provides the beneficial influences of fairly large classes of pupils of about equal advancement. It makes it convenient for boys and girls in rural districts to obtain a high school education without leaving home, and leads to the erection of better school buildings and more satisfactory equipment. It makes it practicable for rural schools to teach nature-

study, manual training and household science, and for advanced pupils to obtain instruction in agriculture, horticulture and allied subjects. It stimulates public interest in the schools and brings to the pupils of a township an institution in which all can have an equal interest and a worthy pride.

THE address given by Sir J. Wolfe Barry on Tuesday, as president of the Association of Technical Institutions, contained several instructive comparisons as to the position of technical education at home and abroad. For instance, he pointed out that while the matriculated students in German technical high schools number 15,442, the number in the whole of similar institutions and universities of Great Britain is only 3873. But it is not so much the number of students as the spirit in which scientific knowledge is regarded that is of importance to national progress. What is wanted, Sir J. Wolfe Barry remarked, is, first, that the highest intellects among us for research as applied to the arts should be rendered available, and secondly, the best possible directing minds should be discovered and utilised in our manufactures. In other words, the man of science should be encouraged to help in the development of industries. Efforts should be made to ensure that industrial leaders are well equipped with scientific knowledge and the principles of technology, and in our schools less time should be given to dead languages and more to the efficient study of science, applied mathematics and other subjects demanded by modern life. Finally, everyone should endeavour, each in his own sphere of influence, to direct, without any exaggeration, but with profound conviction, the attention of our commercial classes to the fact that technical education of the best and most thorough kind is an urgent and crying necessity if we are to maintain a leading position among the nations of the world.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 11, 1902.—"An Error in the Estimation of the Specific Gravity of the Blood by Hammerschlag's Method, when employed in connection with Hydrometers." By A. G. **Levy**, M.D. (London). Communicated by Sir Victor Horsley, F.R.S.

Hammerschlag's method may be briefly described as the adjustment of the specific gravity of a mixture of chloroform and benzol by small successive additions of either constituent until it corresponds to the specific gravity of the blood, the test of the attainment of this condition being that a small drop of the blood, when immersed in the mixture, shall remain suspended without any very obvious tendency to rise or sink. The specific gravity of the mixture is then estimated by means of a hydrometer.

This method is known to be liable to an error of varying magnitude. The investigation into the source of this error resolved itself into a series of observations upon the effect of the low value of the surface tension of the above mixture upon the readings of hydrometers immersed therein. The surface tension of the mixture may be taken as 2·75 mg. per mm., and that of clean tap water as 7·3 mg.

The readings of four different hydrometers when immersed in a mixture of the specific gravity 1·000 are appended:—

No. of hydrometer.	No. 1.	No. 2.	No. 3.	No. 4.
Reading of scale in a chloroform benzol mixture of specific gravity = 1·000	1·002	1·003	1·0095	1·010

The author found, however, that the *calculated* errors exceeded in each instance those *observed*, and the results are contrasted in the following table:—

Hydrometer.	Observed error.	Calculated error.
1	0·002	0·0035
2	0·003	0·0056
3	0·095	0·0123
4	0·010	0·0146

The difference was accounted for satisfactorily by an innate error demonstrated to exist in each hydrometer, evidently due to the standardisation of the instrument in unclean (*i.e.* greasy) water, which possesses a lower surface tension than 7·3 mg. This appears to be a common fault in hydrometers.

Chemical Society, December 17, 1902.—Prof. Emerson Reynolds, F.R.S., president, in the chair.—The following papers were read:—A reagent for the identification of carbamide and of certain other nitrogen compounds, by Mr. H. J. H. **Fenton**. Among the derivatives of methyl-furfural previously described by the author is one which may be either methyl-furil or the isomeric ketone-aldehyde; this in presence of a trace of acetyl chloride gives with carbamide and monoalkyl carbamides a brilliant blue colour.—The rate of decomposition of diazo-compounds, part ii., diazo-compounds of the naphthalene series, by Messrs. **Cain** and **Nicoll**. The reaction is monomolecular, but after a time is not strictly so owing to the formation of azo-colours.—State of carbon dioxide in aqueous solution, by Prof. J. **Walker**. It is shown that obedience to Ostwald's dilution law in the case of solutions of carbonic acid gas and similar substances affords no evidence as to the amount of real carbonic acid present in solution.—Qualitative separation of arsenic, antimony and tin, by Prof. J. **Walker**. The mixed sulphides are dissolved in soda solution and oxidised with sodium peroxide; from the solution, stannic oxide is precipitated by boiling with ammonium chloride, whilst arsenic and antimony can be separated in the usual manner.—The hydrates and solubility of barium acetate, by Prof. **Walker** and Mr. W. A. **Fyffe**. The solubility curve consists of three portions, all convex to the axes and representing the solubilities of a trihydrate, monohydrate and anhydrous salt respectively.—*cis*- and *trans*-ββ Dimethylglutaric acid, and the separation of the *cis* and *trans* forms of substituted glutaric acids, by Messrs. J. F. **Thorpe** and W. J. **Young**.—Constitution of metallic cyanides, by J. E. **Marsh**. Metallic cyanides, with the exception of those of silver and mercury, are oxidised by permanganate to cyanates, whence the author concludes that in general these cyanides have the isonitrile structure, the exceptions being nitriles.—Auto-reduction of mercury and silver cyanides, by Messrs. **Marsh** and **Struthers**.—Note on the action of acids on cellulose, by Miss M. **Gostling**. The black residue formed when cellulose is heated with strong haloid acids closely resembles the artificial humus obtained by the action of dilute acids on sugars.—Nitrotartaric acid and some of its esters, by Prof. P. F. **Frankland**, Mr. H. L. **Heathcote** and Miss **Hartle**.—The nitration of diethylmonobenzoyl and mono-*p* toluyl tartrates, by Prof. P. F. **Frankland** and Messrs. **Heathcote** and **Green**. A preliminary description of these derivatives of tartaric acid.—Interchange of halogen for hydroxyl in chloro- and bromo-naphthalenediazonium hydroxides, by Dr. **Orton**.—Purpurogallin, by Messrs. A. G. **Perkin** and A. B. **Steven**. A description of acyl and alkyl derivatives is given and the products of decomposition by potassium hydroxide are found to be two ketonic substances of the formula $C_{11}H_6O_5$.—Note on the destructive distillation of ethyl gallate, by Mr. A. G. **Perkin**. In addition to pyrogallol and ethyl alcohol, there is formed 7 per cent. of rufigallic acid; the latter is also produced by the distillation of gallic acid itself.—A series of double chromates, by Mr. S. H. C. **Briggs**. A double salt of the composition $(NH_4)_2Ni(CrO_4)_2,6H_2O$ and a second of the composition $(NH_4)_2Ni(CrO_4)_2,2NH_3$ have been obtained, as well as the corresponding salts of copper, zinc and cadmium, by the action of ammonia on the appropriate dichromates.

Linnean Society, December 18, 1902.—Prof. Sydney H. Vines, F.R.S., president, in the chair.—Notes on some Copepoda from the Faröe Channel, by Mr. Thomas **Scott**. Waterlogged and partly decayed pieces of wood are frequently brought up in the dredge, and these fragments harbour Entomostraca. In this manner, some of the rare forms, commented on in this paper, were obtained. Three new species and a new variety of another previously characterised species were described.—The Amphipoda of the *Southern Cross* Antarctic expedition, with remarks on bipolarity, by Mr. A. O. **Walker**. The collection was made between Cape Adare in April, 1899, and Franklin Island in February, 1900, the larger part after the death of the zoologist of the expedition (Mr. N. Hanson) by Mr. Anton Fougner, partly by dredging. The species obtained have a striking resemblance to forms found in Arctic seas, though only one species has been deemed identical, *Ampelisca macrocephala*, Lilljeb. The author does not put forward any theory of his own to account for the similarity of forms in the Arctic and Antarctic regions, with their absence from the intervening tropical seas, but he adduces many instances of it, especially the distribution of the genus Orchomenopsis, Sars, which is widely spread in waters of low temperature. One new genus, Oradarea, is described with a single species, from Cape Adare.

—The deep-sea isopod, *Anuropus branchiatus*, Bedd., and some remarks on *Bathynomus giganteus*, A. M.-Edw., by Dr. H. J. **Hansen.** The aberrant genus Anuropus was described by Beddard in the report of the *Challenger*, vol. xvii., from a single specimen brought up from 1070 fathoms off the coast of New Guinea. The author has recently examined this specimen during a visit to the British Museum, and supplements the original description in several important particulars.

Royal Microscopical Society, December 17, 1902.—Dr. Hy. Woodward, F.R.S., president, in the chair.—Mr. **Rousselet** exhibited an apparatus designed by Mr. H. Bausch for drawing objects natural size. It was described in the Society's *Journal* in 1900, but had not been previously exhibited.—The Rev. R. **Freeman** read a paper by Mr. F. R. **Dixon-Nuttall** and himself on the genus Diaschiza which was illustrated by drawings shown on the screen by means of the epidiascope. The authors alluded to the confusion in which this genus of rotifers had remained to the present time and pointed out the errors into which Gosse had fallen. They described the characters of those species which they considered should be included in the genus and also described a new species.—Mr. E. R. **Turner** gave a description of Lumiére's process of taking photomicrographs in colours.

EDINBURGH.

Royal Society, December 1, 1902.—Lord Kelvin, president, in the chair.—Prof. Cossar **Ewart** read a paper on the callosities of the horse, in which from a study of their occurrence in the fœtus he concluded that the wrist callosity corresponded to the supplementary pad in the foreleg of the dog, and that the hock callosity corresponded to a pad which occurred in the banded ant-eater. There was no evidence of the callosities being remnants of glandular organs. The evidence was rather in favour of Beddard's recent suggestion that they were remnants of tactile organs such as occur in marsupials, lemurs, and the ungulate hyrax.—Prof. **Ewart** also read a paper on a new horse from the Western Islands, *Equus Caballus Celticus.* This newly recognised variety was a pony which took in the west the same place which the Arab took in the east. It agreed with asses and zebras in having no callosities on the hind legs, and it resembled the Przevalsky horse of Central Asia in having short hairs on the upper part of the tail just as in mules. It was yellow dun in colour, had black fetlocks, small head, small ears, prominent eyes, and had stripes and dorsal band, and fragments of stripes on legs, shoulder and face. In many characteristics, it differed decidedly from the Przevalsky horse, and nothing like it was to be found in the east, the recognised home of the Arab. It was found in Iceland, Faeroe, Barra and other small islands of the outer Hebrides, also in Connemara. From the drawings of Palæolithic man and from the bones found in caves, we are able to distinguish two kinds of horses, a large and a small size, and it was suggested that the Celtic pony represented the small-sized horse known to Palæolithic man. The evidence disproved the once prevalent view that all the various breeds of European horses were descended from the one domesticated stock which originated in the east. Dr. Munro thought that Prof. Ewart's paper was of great anthropological importance as furnishing additional evidence as to the continuity of man and his domesticated animals from Palæolithic times, and so giving the *coup de grace* to a fetish which had existed for many years in this country, that Palæolithic man had died out and all his civilisation become extinct before the appearance of Neolithic man.

PARIS.

Academy of Sciences, December 29, 1902.—M. Bouquet de la Grye in the chair.—M. Mascart was elected a vice-president for the year 1903.—On the presence of argon in the gases from the Bordeu spring at Luchon, and on the presence of free sulphur in the sulphurous water from the cave and its vapours, by M. Henri **Moissan.** An analysis of the gases from this spring, carefully collected in the absence of air, showed the presence of 2·56 per cent. of argon, 1·22 per cent. of methane, the remainder of the gas consisting of nitrogen. The water and the vapour from it contained free sulphur.—On a new preparation of the silicon hydride, Si_2H_6, by M. Henri **Moissan** (see p. 233).—Experimental cultures in the Mediterranean region: modifications in the anatomical structure, by M. Gaston **Bonnier.** Experimental cultures of the same species of plant were made in the same soil at Fontainebleau and at La Garde, near Toulon, and a minute account of the anatomical differences observed is given.—On the conditions necessary that a fluid should be in stable equilibrium, by M. P. **Duhem.**—On the velocity with which the different varieties of X-rays are propagated in air and in different media, by M. R. **Blondlot.** X-rays of varying penetrative power were examined, and the velocities determined in air, paraffin wax, beechwood, vaseline oil and essence of turpentine, and it was found that within the limits of experimental error the velocity of the different varieties of X-rays was the same in all the media, being equal to that of light in air.—On the germinating power of seeds exposed to sunlight, by M. Emile **Laurent.** Sunlight exerts an injurious influence upon the seeds or dried fruits of the higher plants, the first effect being a delay in the germination and then the death of the embryos. In general, moderately bulky seeds are less sensitive to the effects of sunlight than smaller ones, especially if the latter have dark coatings.—Notice on M. Millardet, by M. **Bornet.**—Anomalies of the earth's magnetic field on the Puy de Dome, by MM. B. **Brunhes** and **David.** Report by M. Bouquet de la Grye.—New observations on the volcanic eruptions at Martinique, extracts from letters addressed by M. **Lacroix** to MM. Darboux and Michel Levy.—Observations of the comet *d* (1902) made at the Observatory of Algiers with the 31·8 cm equatorial, by MM. **Rambaud** and **Sy.** Observations of magnitude, apparent positions of the comet and of comparison stars.—Observations of the Perseids, Leonids and Bielids made at Athens in 1902, by M. D. **Eginitis.** The Perseids were observed under favourable conditions between August 8 and 13; they were less numerous than in the five preceding years. The conditions for the observation of the Leonids and Bielids were not so favourable.—On entire functions, by M. **Hadamard.**—Remark relating to my note on the approximate representation of functions, by M. W. **Stekloff.** A correction of an error in a previous note.—On the fundamental formula of Dirichlet relating to the determination of the number of classes of definite binary quadratic forms, by M. Mathias **Lerch.**—An application of the theory of residues to the analytical prolongation of Taylor's series, by M. Ernst **Lindelof.**—On a plane representation of space and its application to graphical statics, by M. B. **Mayor.**—Study of the magnetofriction of the anode bundle, by M. H. **Pellat.** In previous papers, the author has described a series of phenomena which are produced when a kathode or anode flux is submitted to the action of an intense magnetic field and which are inexplicable by the laws of electromagnetism. The assumption of the existence of an anisotropic friction affecting the particles in motion, very great in the sense perpendicular to the lines of force of the magnetic field and much less in the direction of the lines of force, serves to explain the observed phenomena perfectly, and the name magnetofriction is proposed as a general name for this phenomenon. Experiments are described in which the effect of varying the pressure and nature of the gas is shown.—On the emanation from phosphorus, by M. Eugène **Bloch.** It has been known for some time that air placed in the neighbourhood of a stick of phosphorus becomes a conductor of electricity. The study of this phenomenon having led to contradictory explanations in the hands of Barus, G. C. Schmidt and Harms, further experiments have been carried out by the author, who concludes that the conductivity of dry air which has passed over phosphorus is due to ions of very feeble mobility which serve as nuclei of condensation for water vapour, even non-saturated. The question of the exact chemical mechanism by which these ions are produced, whether their formation is due to the production of a definite chemical compound such as ozone or an oxide of phosphorus, or to a simple modification of the oxygen, requires further study.—On the Hall effect and the mobility of the ions of a saline vapour, by M. Georges **Moureau.**—On a new electric accumulator, by M. D. **Tommasi.** A description of the method of constructing the lead plates of an accumulator. The capacity obtained is 17·7 ampere-hours per kilogram of plates.—On the spectra of flames, by M. C. de **Watteville.** The method of M. Gouy is applied to the study of flame spectra in the ultra-violet. The results given tend to show that temperature is the only factor which influences the constitution of spectra.—On the proportion of hydrogen in atmospheric air, by M. Anatole **Leduc.** A reply to the criticisms of M. A. Gautier, the author maintaining the accuracy of his original conclusions.—The thermal study of metaphosphoric acid, by M. H. **Giran.**—On some sources of mineral gases, by

M. Ch. **Moureu.** An analysis of the gas arising from mineral springs in the region of the Pyrenees. All the gases examined contained argon in amounts varying from 0·9 to 1·8 per cent. Only one of the five samples examined could be shown to contain helium.—On cryolites, by M. E. **Baud.** A thermochemical paper.—On a new method for the volumetric estimation of hydroxylamine, by M. M. L. J. **Simon.** Hydroxylamine oxalate can be titrated with potassium permanganate in neutral solution in a perfectly definite manner, and an exact method for the titration of any salt of hydroxylamine can be based upon this fact.—On the method of manufacture of arms of the bronze period, by M. F. **Osmond.** By the application of the methods of micrographic analysis to specimens of ancient bronze implements, it has been found possible to trace differences in the mode of manufacture, and it is regarded as possible that a methodical study on these lines may lead to the classification of bronze implements with regard to time.—On the composition and constitution of the hydrates of sulphuretted hydrogen, by M. de **Forcrand.** The method of study is based upon the measurement of the dissociation pressures.—On the dibromide of metho-ethenylbenzene, by M. M. **Tiffeneau.**—On the synthesis of an aromatic hydrocarbon derived from camphor, by M. C. **Chabrié.** A study of the interaction of benzene and monochlorocamphor in the presence of aluminium chloride.—On a method for transforming monochloro- and monobromo-derivatives of hydrocarbons into monoiodo derivatives, by M. F. **Bodroux** (see p. 233).—On the decomposition of some di- and tri-basic organic acids, by MM. Œchsner de **Coninck** and **Raynaud.** Malonic, succinic, tartaric, malic and citric acids were heated with glycol, glycerol and with sulphuric acid, and the decomposition products noted.—On the nature of the nitrogen compounds which exist in the soil at different heights, by M. C. **André.**—Normal hermaphrodism in fishes, by M. Louis **Roule.**—Organic variations in carnivorous fowls of the second generation, by M. Frédéric **Houssay.**—On the origin of the *Nebenkirn* and the nuclear movements in the spermatid of *Notonecta glauca*, by MM. J. **Pantel** and R. de **Sinéty.**—On the otocysts of polychætal annelids, by M. Pierre **Fauvel.**—On the nuclear emissions observed in the Protozoa, by MM. A. **Conte** and C. **Vaney.** The conclusion is drawn that the nucleus takes part directly in the formation of zymogen grains, and consequently it is of high importance in the phenomena of digestion, both intracellular and extracellular.—The organisation of *Trepomonas agilis*, by M. P. A. **Dangeard.**—On intermediary wood, by M. Paul **Vuillemin.**—The influence of formaldehyde upon the vegetation of some fresh-water Algæ, by M. Raoul **Bouilhac.** In presence of light, certain moulds can grow in solutions containing small quantities of formaldehyde, and can utilise the latter as food.—On the vegetation of Lake Pavin, by M. C. **Bruyant.**—On a conidian form of the fungus of black rot, by M. C. **Delacroix.**—On some connections between the genesis of metalliferous layers and general geology, by M. L. de **Launay.**—On the age of the old volcanic formations of Martinique, by M. L. **Giraud.**—On the discovery of a new granitic *massif* in the valley of the Arve, between Servoz and Les Houches, by MM. E. **Haug** and P. **Corbin.**—Cryogenin in fevers, by M. **Carrière.** Cryogenin (metabenzaminosemicarbazide) has a marked effect in lowering the body temperature, especially in the case of fevers, and appears to be free from toxic properties. Its antithermic action is variable, but is especially strong in tuberculous subjects.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 8.

MATHEMATICAL SOCIETY, at 5.30.—A Method of representing Imaginary Points by Real Points in a Plane: Prof. A. Lodge.—On the Mathematical Expression of the Principle of Huygens: Dr. J. Larmor.—Generational Relations for the Abstract Group simply Isomorphic with the Linear Fractional Group in the Galois Field [2^n]: Prof. L. E. Dickson.—Series connected with the Enumeration of Partitions (second paper): Rev. F. H. Jackson.—On the Jacobian of Two Binary Quantics considered Geometrically: Prof. W. S. THE HOLY SHROUD OF TURIN.

Le Linceul du Christ; Étude scientifique. By Paul Vignon, Dr. è Sci. Nat. Pp. 207 and 9 photogravures. (Paris: Masson et Cie, 1902.)

The Shroud of Christ. By Paul Vignon, D.Sc. (Fr.). Translated from the French. Pp. 170; 9 photogravures and collotype plates and 38 illustrations. (Westminster: Archibald Constable and Co., Ltd., 1902). Price 12*s.* 6*d.* net.

WHETHER the relic described, figured and discussed in this handsomely got up volume is the veritable shroud which enwrapped the body of Christ is a question which need not be seriously considered in the columns of a scientific publication. Dr. Vignon seems to have convinced himself that the relic is genuine, and his object in publishing this work is (presumably) to convince his readers, or at any rate to place before them the evidence on which his conclusions are based. So far as the antiquarian evidence goes, it will suffice to remind readers of NATURE that during the recent controversy—which appears to have been the last of a series of controversies concerning the authenticity of the relic in question—Father Herbert Thurston, S.J., communicated a letter to the *Times* of April 28, from which we make a few extracts:—

"The Abbé Ulysse Chevalier claims to have proved to demonstration that the linen winding-sheet exhibited at Turin is a spurious relic manufactured in the fourteenth century, and, as the writer believes, with fraudulent intent."

"We are not, of course, in any way bound to believe that those responsible for the subsequent veneration of this alleged relic have been guilty of conscious fraud. It may even in the first instance have been fabricated without intent to deceive. . . . Just as in the case of so many facsimiles of the Holy Vails, what was in the first instance a mere copy for devotional purposes has come in time to figure as an original, the wish, no doubt, being father to the thought, but probably without any deliberate insincerity."

Thus, out of the seven chapters composing this work, there are but two which come within our province, viz., chapter vi., in which the author deals with the scientific evidence, and chapter vii. more particularly, in which he puts forward an explanation of the image which is to be seen on the shroud. The antiquarian lore of the preceding chapters has no particular interest for us, and we may add, further, that the question whether the shroud is the real article or whether it was "faked" in the fourteenth century is a point which in no way affects the discussion of Dr. Vignon's scientific evidence, because the explanation with which we have to deal is equally miraculous whether the image is some twenty centuries old or whether it is only six hundred years old.

It will be necessary, in order that our readers may judge the issue raised by Dr. Vignon's *étude scientifique*, to give a brief description of the relic, facsimile reproductions of which are given in photogravure plates showing respectively the full-length image and the head only on an enlarged scale. The impression, according to the description and figure, is that of a human body undraped, with hands crossed, with a long face terminating in a beard, with hair over the lips and long hair lying along each side of the face; in brief, the face of Christ as made familiar by the great masters of the old Italian school. This description, of course, applies only to the front aspect. The back view is such as would be presented by the same body if seen from behind or if it produced an impression on the linen while lying on its back, the front aspect being produced (on the assumption that it is an impression) by drawing the same shroud lengthways over the face of the prostrate body. The shroud would evidently in these circumstances (again assuming that the body impressed its image) show the two figures, front and back view, on being opened out, the figures being joined head to head, and this is declared to be the state of affairs visible on the holy shroud. The image is said to be formed of reddish-brown shades and—what is of fundamental importance to the author's theory—the lights and shades are reversed, *i.e.* the impression corresponds to a photographic negative. In consequence, the true aspect of the features only appears when the image is reversed by being photographed, and this is well shown in the plates referred to, from which the reader will be enabled to compare the image with its photographic reverse. There are many other marks on the shroud which are caused by rents, stains, burns, pieces clipped out, &c., all of which naturally appear in the photographs. We fail to see the importance of the over-elaborated details of description with which the author treats of these marks, unless it be to establish his claim for the authenticity of the relic from the antiquarian point of view. With this we have nothing to do here; scientifically, these marks appear to us to have no value whatever.

It remains to be pointed out that the author, so far as can be gathered from his writings, has never seen this relic himself, but has relied upon the descriptions of others, upon a water-colour copy made in 1898 and upon photographs taken by M. Pia, by M. Fino and others in the same year when the shroud was allowed to be on view for eight days. We suppose that Dr. Vignon is satisfied that the image, as it appears on the shroud, is really a negative impression and that the photographic plates have not been tampered with, although we confess that for an *étude scientifique* we should have expected some more substantial and first-hand verification of these fundamental statements. We will, however, let all this pass and meet the author half-way, and admit that there is a negative image of a human figure on the linen, and this brings us to the core of the subject, which is embodied in the query:—Apart from the question of age, how was this image produced?

Now according to the author's descriptions, which, we may repeat, are given in ridiculously minute detail, there are visible on the head and on the body itself certain marks which we are asked to believe to represent blood stains, lacerations and wounds, and we are even given an illustration of the particular kind of "flagrum" with metal buttons which the Romans used. In fact, the description as given by the New Testament writers is, if we are to accept the author's statements, so faithfully and so minutely verified by the figure on the shroud that the ordinary reader who is not thirsting for

new "evidences," but who is simply anxious to know the actual facts of the case, will probably come to the conclusion that Dr. Vignon is either the victim of credulity or that he has overdone his evidence to such an extent as to have damaged his own reputation as an expert scientific witness. The plates certainly do not tally with the details of the markings as described in the text; but here again it may be that there is much lost by the heliographic reproduction and that the author is describing the original photographic plate, which he is careful to inform us was taken by M. Pia on an Edward 50 × 60 isochromatic film sensitive to yellow, with a yellow screen, a Voigtländer lens, a diaphragm of 7 mm. diameter and an exposure of 18 minutes, the shroud being illuminated from the front by two powerful arc lights at 10 yards' distance from the surface. We will therefore again waive an objection which might be raised against the author's special pleading on behalf of the shroud, and we will admit that there are marks on the face, body and limbs in the original plate which we cannot see in the heliogravures reproduced from it—certainly no such marks are distinctly recognisable in the front view, whatever interpretation may be put on the blotched appearance on the body in the back view.

The simplest, the most obvious and the only straightforward answer to the question how the image was produced is that it is a time-worn painting—how, when or why executed being beyond our province of inquiry in these columns. Dr. Vignon, however, is so emphatic in his repudiation of this idea that he fires off a whole battery of arguments in the sixth chapter in order to demolish the sceptics who from the fourteenth century downwards have taken this not altogether unreasonable view of the relic. One or two of these arguments may be dealt with on their own merits as appealing to scientific principles. He lays very much stress, for example, upon the circumstance that the impression is a negative one, arguing therefrom that no forger could possibly have painted a figure intentionally with lights and shades reversed. May we ask why not? As an artistic feat it does not seem altogether impossible, and distinguished artists whom the reviewer has consulted inform him that, not only is such a style easy of execution, but that a forger who wished deliberately to convey the impression that the image was produced by contact of the body with the shroud would, if skilful, intentionally adopt such an artifice. Then again, it is stated (p. 123, English ed.) that the image cannot be a painting (*i.e.* in pigment) because it would have faded with the lapse of time instead of becoming darker. Again we ask why? In the first place, where is the evidence that the image has become darker? In the next place, accepting Dr. Vignon's own explanation, which shall be considered subsequently, why should a "vaporographic print" (to use the author's term) be more permanent than a painting? An organic colouring-matter developed on the linen by the hypothetical process advocated in this work is not more likely to withstand the influence of time than a painting. The argument appears to be:—It has not faded, therefore it is not a painting. It is not a painting, therefore it is a chemical (vaporographic) impression. Readers of this review will see that little value can be attached to such inferences.

Having dismissed the theory of artistic forgery—at any rate to his own satisfaction—the author proceeds to demolish the view that the image is a contact impression. With this conclusion we quite agree. The only way that such an image could be produced by contact would be for the body to be uniformly coated with pigment and then for the supple shroud to have been pressed over and into every elevation and depression in the body. We are all familiar with the appearance of images produced by such means, and a glance at the figure on the shroud with all the details of the features and the hair will suffice to show that such an impression on linen, however supple, could never have been obtained by mechanical contact—even supposing the preliminary preparation of the body with pigment were conceded. Nothing short of a plaster cast could reproduce features such as appear in the plates. The martyrdom which Dr. Vignon must have suffered in allowing his face (with a false beard) to be smeared with red chalk in order to see what kind of impression could be obtained from it by such means will be credited to his zeal, although the publication of the blurred results in the form of a heliogravure plate seems quite superfluous.

Having thus shown how the image could not have been produced, the author proceeds to the development of his own hypothesis. The impression is not a photographic negative in the ordinary sense, but it is a genuine chemical impression produced by emanations from the body acting on the shroud, "sensitised" by the materials used for its impregnation. The emanations were not of the same kind as those proceeding from radio-active substances, but were more of the nature of vapours. Appeal is made to Dr. W. J. Russell's experiments in order to show the analogy between the images produced by the emanations from zinc, resinous substances, &c., and that on the shroud. Prof. Colson has cooperated with the author, and between them they have produced what by courtesy the writer of this notice proposes to call Russell-types of coins and busts (prepared by coating with zinc powder) on photographic plates.[1] Photographic reproductions of these are given in the volume under notice. From these figures, it will be seen that the impressions produced are really very poor as compared with the originals. The head on the coin, for example, is full of detail; its Russelltype, after photographic reversal, shows but a blurred and hazy image. Of course, the emanations from the body did not consist of zinc vapour, nor was the shroud coated with gelatino-bromide emulsion, so there may be no real analogy between the images—even on the "vaporographic" theory of Dr. Vignon. The emanations of the body, according to the author, proceeded from "febrile sweat" which bathed every portion of the body, hair included, and the sensitive material which enabled the shroud to receive the impression was, or may have been, a mixture of oil and aloes. There is nothing antecedently improbable in the supposition that emanations from a dead body, especially if ammoniacal as supposed by the author, may produce a coloured impression on a sensitive vegetable colouring-matter. So far there is just enough *vraisemblance* in the hypothesis to lead the

[1] Prof. Colson, by the way, has come to the conclusion that the emanations from zinc really consist of zinc particles, and it is these which penetrate the sensitive surface and produce the photographic effect. This explanation is at variance with the hydrogen peroxide theory of Russell.

unwary to think that Dr. Vignon has established his case. As his work professes, however, to be an *étude scientifique*, and as he unhesitatingly lays down the conclusion that the shroud is the real article (Popes, Bishops and Jesuits notwithstanding) and that the image is a "vaporograph" produced in the manner described, it is of considerable importance that his evidence should be critically considered.

In order to clear the ground, we will make a most liberal advance in Dr. Vignon's favour and concede for the sake of argument that such ammoniacal vapours may be emitted as required by hypothesis, and further, that the shroud may have been impregnated with some sensitive colouring-matter or colour generator capable of receiving an impression in three days. What kind of impression could be expected in these circumstances? Stretching the hypothesis to its utmost limit, certainly only a blurred human figure in outline. Now look at the image on the shroud; features with a recognisable expression, hair in detail and (as per description) blood stains, wounds and stripes. Surely, as the author himself says (p. 43), "There is no limit to hypothetical ingenuity."

A scientific witness must, however—whether his hypothesis be reasonable or otherwise—be expected to give some substantial evidence for a hypothetical belief, and the more unlikely the hypothesis, *a priori*, the stronger must that evidence be. Here is what Dr. Vignon has to offer:—

"We took the plaster cast of a hand and covered it with a glove of suède kid. We then poured some of the ammoniacal solution (ammonium carbonate in water) along the wrist so that it penetrated the plaster without completely saturating the glove. The vapours were given off very regularly through the pores of the kid without staining the linen by too much water or letting the oil penetrate the damp glove.

"Working in this way we got an excellent impression of the back of the hand (on linen impregnated with olive oil and aloes). The tips of the fingers have the square aspect due to the glove having been too long. On the inside of the thumb the seams of the glove are plainly to be seen, while on the outside the image fades away rapidly and regularly. *The print is sufficiently definite to show the likeness of a finger, but too diffuse to mark the actual outlines, and this may be said of all the fingers.* (Italics ours. Compare with the hands on the figure on the shroud where the fingers are distinct.) . . .

"The print which we have obtained of this hand justifies us in asserting that under special conditions ammoniacal vapours may produce as distinct impressions of an object as those shown on the Holy Shroud" (p. 167).

Dr. Vignon's scientific conscience must really be very easily satisfied. This is the only scrap of experimental support that he furnishes. No illustration of the "vaporographed" hand is given. It is confessed that the experiment is so delicate that an attempt to repeat it gave a worse result than the first. A plaster bust of Michael Angelo refused to furnish any recognisable impression. Yet with these inconclusive results, the author virtually claims to have settled the whole history and origin of the relic. Just when he comes to the very point where scientific evidence becomes possible, he meets with what appears to the reviewer to be a failure, and then naïvely remarks:— 'We shall continue these experiments if desirable, though they only present a limited interest" (p. 167). The magnitude of the conclusions based on such lame experimental evidence justifies the condemnation of the whole work as an *étude scientifique*. To the reviewer, it reads like an antiquarian dissertation ending in a pseudo-scientific anti-climax. The conditions required by the hypothesis are not difficult to realise experimentally. There are many organic colouring-matters sensitive to ammonia gas. The fever hospitals would surely furnish the author with subjects for experiment if inanimate models of the human figure are considered unsatisfactory. If by ammoniacal or any other vaporous emanation Dr. Vignon can succeed in producing an impression as distinctly recognisable as a likeness as the image on the shroud in all its details, we will waive the question of twenty centuries' permanence and go so far as to admit that there is at any rate some justification for "vaporographic" portraiture. As the "explanation" stands now, it is purely in the region of hypothesis, and pending that rigorous verification required by science, we consider that the author's case is "not proven." If there are any scientific readers who are convinced that the conclusions in this work are satisfactorily established, we shall be disposed to credit the shroud with having wrought a greater miracle than was ever ascribed to it by the Chapter of Lirey in the fourteenth century.

R. MELDOLA.

IRISH FOLKLORE.

Traces of the Elder Faiths of Ireland. A Folklore Sketch. By W. G. Woods-Martin, M.R.I.A. Vol. i., pp. xix + 405; vol. ii., pp. xv + 438. (London: Longmans and Co., 1902.) Price 30*s.* net.

"MANY readers may have read works treating of some one or more epochs included in the past of which Ireland has been the scene, but up to the present," says the author, "this lengthened period has not been treated as a whole." Such a complaint can no longer be made after the publication of this able and comprehensive work, which is, as its second title indicates, "A Handbook of Irish Pre-Christian Traditions."

The consideration of the main subject of the book, the faiths of Ireland, is preceded by about 120 pages of introductory matter concerning the geographical shape of the island, the Great Ice Age and the nature of the earliest inhabitants. Excellent illustrations are given of the effects of the Great Ice Age in moulding the sides of the hills, &c. In the enumeration of the various theories as to the causes of the Ice Age, a suggestion is made as to the significance of the sun being a variable star. This fact may possibly explain the whole mystery. Though not often mentioned by the theorists, namely by those who are in favour of Sir C. Lyell's geographical explanations or of Croll's astronomical arguments based on the variability in the shape of the earth's orbit, it cannot have been outside their views. If, for instance, it be true that, in the time of Ptolemy, α Geminorum (*Castor*) was the brighter, and, therefore, presumably the hotter, star than β (Pollux), we may suppose that the inhabitants of the planetary dependents of the former are now experiencing a glacial or those of the latter a torrid epoch.

Ireland seems to have been the home of the gigantic

deer, their increase being explained by the total absence of lions from the island.

The earliest inhabitants of the country migrated, it would seem, from the south-west of Scotland into Ulster. According to the author, the fact that the skulls of these early inhabitants are often rather larger than those of the average of the masses inhabiting the great cities of the present day is explained by the intelligence needed for defence and for the procuring of food.

"Indeed, on the principle of the survival of the fittest, it could only be the robust who lived through the hardships and climatic exposure incidental to a savage life."

The author, in his summary, admits the theory of evolution, though under the direction of the Great First Cause.

Even as late as the time of the Spanish Armada, the inhabitants of Ireland were described as follows by Captain Cuella, who escaped from one of the wrecks off the Irish coast:—

"They live in huts made of straw. The men have big bodies, their features and limbs are well made and they are as agile as deer. They eat but one meal a day, and their ordinary food is oaten bread and butter. They drink sour milk, as they have no other beverage, but no water, although it is the best in the world. They dress in tight breeches and goatskin jackets, cut short, but very big, and wear their hair down to their eyes."

It is not surprising that such a race should entertain the curious ideas so abundantly described in the author's pages.

Nowhere in Ireland has discovery as yet been made of any Palæolithic art like the extraordinary and life-like incised sketches of men and animals made by the cave-men of Gaul. No representations of human or animal forms seem to have been made prior to the introduction of Christianity. Even then, they were of an arabesque character and subsidiary to the scroll work in which they were entwined. Nor does iron appear to have been introduced into Ireland until the fourth century, A.D.

It is difficult to fix the point where real Irish history commences. An interesting map of Ireland according to Ptolemaic geography is reproduced on p. 230. There is said to have been no Roman colonisation, though Roman objects were, of course, imported. An illustration is given (p. 237) of a Roman medicine stamp of smooth grey slate found in the county Tipperary. It was probably used to stamp a "patent medicine" made and sold by the Romano-Hibernian dealer whose name it bears.

In the chapter which deals with stone worship, there seems to be so little, so far as Megalithic remains are concerned, which can be illustrated from Ireland that the chief example has to be drawn from Carnac, in Brittany. One circle of stones, indeed, is introduced, named the Druids' circle, near Killiney, which consists of seven small stones and two uprights large enough to be called *giants*. There are no data, however, given from which the age of the work, as in some of the Megalithic circles in Great Britain, could be investigated, and there is only one instance, and that a doubtful one, of anything of the nature of the alignments in Brittany which can also to some extent be interpreted astronomically; but there are numerous and very curious examples of perforated stones which have been employed even in comparatively recent times for passing children through in hopes of curing them from various disorders. These holes, in some instances, are large enough to allow grown-up people to creep through them, though generally with difficulty. Sometimes the holes were only large enough to admit the arm, or even the thumb and fingers, to be passed through them. Marriage contracts, it is said, are still ratified in this way, country couples signifying betrothal by clasping hands through the hole. Such practices, it is shown, were not confined to Ireland, but the evidences seem to be very greatly multiplied in that country. The history is given of the *Stone of Destiny*, as it was called, which is now placed under the Coronation Chair in Westminster Abbey. This supposed magic stone, which roared like a lion when a legitimate king stood upon it, was, it is alleged, sent to Scotland in the ninth century in order to secure the then dynasty on the throne. It was preserved with great care at Scone, in Perthshire, until 1296, when it was carried off by Edward I. of England.

Lovers of folklore will find in this book abundant illustrations of that subject, and among them many examples of prehistoric practices surviving into recent and even modern times.

MIGRATORY LOCUSTS.

Die Wanderheuschrecken und ihre Bekämpfung in unseren afrikanischen Kolonieen. Von Dr. L. Sander. Pp. 544. (Berlin: Reimer, 1902.) Price 9 marks.

AFRICA has always been exposed to the ravages of migratory locusts, the fringe of cultivation on the borders of extensive deserts or wildernesses being peculiarly favourable to their attacks; and this applies more especially to the north and south of the continent. Dr. Sander's volume is a carefully compiled account of their ravages in the German colonies of Africa during the last ten or twelve years, for though travellers and missionaries have left us accounts of earlier invasions, yet the first disastrous appearance of locusts in East Africa since the German occupation was in the years 1894 and 1895, when a serious famine was the result. A graphic account is given by a native of Pangani, from which we may extract and condense a few sentences:—

"In December there came vast swarms, so that the heavens were covered by them, as if with black clouds. The locusts have devoured everything in the country, especially lentils, peas and bananas. We are in a sad state here, for they have devoured the whole harvest, and it will take years to repair the damage. First we must dig over the whole country, for the locusts have devoured everything, root and branch. Second, we must buy fresh seed, and that will cost much money. Third, we must buy our food from the traders for the present, for we have nothing left to live upon. The locusts have been here in vast swarms since November and December, and have not yet retired. We have the black and yellow ones here, and red ones too. Our largest landowners and sugar manufacturers have removed to Pangani because their plantations lie wasted. Each of these gentlemen has hundreds of workmen to provide for. For the present, there is no thought of the retreat of the creatures. I tell you that when a swarm comes, we can often scarcely see the sun. The locusts

are greedy beyond expression. A European laid out some cotton and coffee to dry in the sun, and when he looked for it after a time the locusts had devoured it all —cotton, coffee, and even the blankets on which the raw material had been spread out." Since then, the locusts have never left the district, and were again very destructive in 1898 (pp. 7, 8).

In South-west Africa, various locust invasions are noticed, from 1831 to the present time; and it is recorded that at Barmen (in the present Orange Colony) in 1866, the

"Fussgänger" (immature locusts) "not only devour all the plants, green or dry, before them, but everything that they can find, including linen and clothes left unprotected; for they creep into the houses even to the bedrooms, and eat up everything" (p. 20).

A pitiful story comes from Little Namaqualand in 1873:—

"On the morning of May 5 I held a prayer-meeting to implore the Lord to send us a little rain, and to put an end to the great drought and distress. In the afternoon clouds actually rose, and we heard a rushing in the air as if it was about to rain; but, alas! the noise was caused by swarms of locusts, which covered the whole place, and completely devoured the little dry grass that was left" (pp. 21, 22).

One is forcibly reminded of the old story of the Adites, who sent a deputation to Mecca to pray for rain, and were answered by a black cloud which sent forth a desolating wind which exterminated the whole tribe.

After discussing the ravages of locusts in the various territories of German Africa, Dr. Sander proceeds to give a full account of the habits, transformations, biology, &c., of the most destructive species of African locusts, and also discusses the best means of contending with their ravages; and the natural enemies of locusts (birds, &c.) are also noticed. Without being overloaded with illustrations, there is a sufficiently good series in the text to render the subject intelligible to the general reader. An appendix contains an interesting edict of Frederick the Great, ordering the destruction of locusts in Prussia in 1753. Dr. Sander's maps illustrate the prevalence of the pest in German East Africa from 1897 to 1899, and in Cape Colony and South-western Africa from 1891 to 1900. His book, though written, of course, for the benefit of the German colonies in Africa, deserves the most serious attention from all who are interested in the welfare and prosperity of our own African possessions.

W. F. K.

OUR BOOK SHELF.

Applied Mechanics for Beginners. By J. Duncan, Wh.Ex., A.M.Inst.C.E., &c. Pp. x+324. (London: Macmillan and Co., Ltd., 1902.) Price 2*s.* 6*d.*

WITH the development of the mechanical laboratory in technical schools and colleges, the teaching of mechanics has in recent years undergone a quiet revolution. Experiments are no longer confined to the few made by the teacher, but the students now all take a share in this kind of work, which has become an important part of the school or college course, being of great value, as affording the training in inductive methods which in former times was often neglected.

The volume under review shows the influence of these prevailing conditions. A considerable portion of the book is devoted to the description of laboratory appliances, the methods of making tests and the kind of information to be got therefrom. Some of the apparatus is of quite a simple character, such as a student may readily make and use at home, and yet from which fundamental mechanical principles can be verified and illustrated in a satisfactory manner. In other cases, the experiments are more elaborate; those dealing with hydraulics strike us as being particularly good.

Another important part of a course in applied mechanics is the working of many numerical examples; here also the requirements are well met, and the student is amply provided with material in great variety. The answers to the examples are given at the end of the volume.

There are a few defects which may probably be remedied in great measure in a future edition. The diagrams are well drawn and clearly printed, but in some cases the letters of reference are unfortunately too small. The author is not very happy in his definitions of the engineer's units of mass and force, and occasionally his enunciations of fundamental principles of mechanics could be improved by revision. The treatment of vectors is rather weak. We should like to have seen more use made of the *radian* measure of angles and angular velocities in the many problems involving rotation.

These faults do not detract materially from the general merits of the book, which is one that can be confidently recommended for the use of students who are beginning the subject of applied mechanics and wish for guidance in obtaining an experimental knowledge of the foundations on which the science is built, and for an account of many of its applications in the arts.

Compte rendu du deuxième Congres international des Mathématiciens tenu à Paris, 6 au 12 Aout, 1900. Pp. 450. (Paris: Gauthier-Villars, 1902.)

AMONG the innumerable congresses held at the Paris Exhibition, this one dropped completely out of sight. On arrival at the advertised place of meeting in the Hall of Congress, it was found occupied already by some 1500 deaf-mutes, assembled in conclave; naturally they could give us no information. The Mathematical Congress was discovered at last, on the top floor of the Sorbonne, where it was left severely alone by the French professors, too dignified to meet the herd of visitors on equal terms.

The Physical Congress, held simultaneously, carried off all but the mere pure mathematicians, who enjoyed themselves by reading papers to each other on arithmetic and algebra, analysis and geometry, bibliography and teaching methods.

An eloquent address by M. Poincaré, the president, who put in an appearance at the closing ceremony, on the *rôle* of intuition and logic in mathematics, an extract from a lecture by Mittag-Leffler on a page of the life of Weierstrass, Hilbert's discourse on the mathematical problems of the future, and communications by M. Cantor on mathematical historiography and by Vito Volterra on Betti, Brioschi and Casorati, these form the most important part of the volume.

Wood: a Manual of the Natural History and Industrial Applications of the Timbers of Commerce. By G. S. Boulger. Pp. viii + 369. (London: Edward Arnold, 1902.) Price 7*s.* 6*d.* net.

THE contents of this ugly volume, of heavy paper and with narrow margins, are more worthy of attention than its exterior suggests, and comprise an immense amount of information about the timbers of commerce from many points of view. That it is a compilation which would probably never have seen the light had not the works of

Hartig, Nördlinger, Laslett and Marshall Ward preceded it may be a safe surmise, but the author has done his work much in his own way, and, on the whole, has done it well, and acknowledges his indebtedness to the above and to other writers. The longest section, that on the sources, characters and uses of the woods of commerce, which occupies more than two hundred pages of the three hundred and fifty composing the book, abounds in interesting facts about the foreign and colonial timbers now so largely imported into this country, though why the word "Acacia," on p. 141, is limited to "Robinia" and "Eucryphia" is the more puzzling since the author shows, on p. 341, that the wattles of Australia are the true plants of that genus.

The sections on the recognition and classification of woods, on seasoning, on the supplies of wood and on testing are also good; those on the origin, structure and development and on the defects of wood are less so. Indeed, the whole subject of the microscopic structural characters is very poorly treated, and the appendix on the microscopic examination of wood might as well have been omitted. This is a pity, since it is just in this direction that so much interesting and important work has been done of late, and the author's meagre treatment of this theme and his omission of any mention of the publications of Müller, Mer, Strasburger and other investigators suggest that he is here on unfamiliar ground. Moreover, certain slips, such as the confusion of the schlerenchyma of a peach stone with wood (p. 2), the denial of wood to the so-called herbaceous plants and the retention of the term "exogenous" (p. 3), the inadequate treatment of cellulose (p. 6), the denial of tracheæ to the protoxylem of Conifers (p. 19) and the explanation of the term "desmogen," are signs pointing to the same conclusion.

On the other hand, there are some capital photographic reproductions of the appearances of various woods in transverse sections, and the material is well arranged and rendered accessible by what appears to be a very complete index.

L'Eau dans l'Alimentation. By F. Malméjac. Pp. 312. (Paris: Felix Alcan, 1902.) Price 6 francs.

IT is quite true, as the author of this work states, that the great problems connected with the purification of water and its safety or danger when used for drinking purposes are not yet solved, but although he claims—and not without reason—that his work is something more than a compilation, inasmuch as it contains results of special study on the points which have appeared to him the least clear or the more controversial, the reader who has studied, say, the works by Thresh or Mason on the subject will find little to learn from the present volume.

The work is certainly a useful and interesting one, but it scarcely justifies the eulogistic preface written by M. F. Schlagdenhauffen, honorary director of the Higher School of Pharmacy of Nancy, from which the reader would conclude that the present volume was almost an epoch-making contribution to an important subject.

The book is divided into five parts, which are subdivided into chapters. The first part deals with water in general, including the microscopic, the chemical and the bacteriological examinations, and the other four parts deal with the organic matter of water, the germs of water, the filtering value of different earths and the purification of water.

Our Dogs' Birthday Book. Arranged by Mrs. F. H. Barnett. With Twelve Pictures of Champion Dogs. Pp. 144. (London: George Allen, 1902.)

A BIRTHDAY book of the familiar kind, except that the quotation under each day of the year is concerned with dogs.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Hydrographical Work of the North Sea Investigation Committee (Scotland).

IN weather of exceptional severity, Lieutenant and Commander Sharp, of H.M.S. *Jackal*, has just brought his second hydrographical cruise to a successful issue. The *Jackal* left Aberdeen on December 4, and followed approximately the same course (on lines laid down by Mr. H. N. Dickson) as on her autumn cruise in August-September (*cf.* NATURE, October 30, 1902), that is to say, northwards to Lerwick, thence in a north-easterly course to near the Norwegian coast, then westward to Faeroe and back along a somewhat more southerly track, passing between Shetland and Orkney and out into the North Sea as far as the meridian of 0°. The last observations were made on December 15. About 125 water-samples were obtained at various depths, in full series, at twenty stations, and surface samples were collected in addition hour by hour. Captain Sharp bore, on this occasion, the whole responsibility of collecting the samples and observing the temperatures, and I venture to think that, in spite of the worst possible weather, he has achieved remarkable success. The water-samples are being estimated in the laboratory of my colleague, Prof. Walker, and when this work is done, the whole of the data will be handed over to the hydrographers; but the temperature records are in themselves interesting, so much so that I think it right to publish them in the following brief abstract.

The stations were as follows (numbered according to those of the August cruise with which they approximately correspond:—ii., 58° 36′ N., 1° 46′ W.; iv., 59° 17′ N., 1° 30′ W.; vi., 60° 37′ N., 0° 30′ E.; vii., 61° 12′ N., 1° 52′ E.; viii., 61° 40′ N., 3° 4′ E.; ix., 61° 39′ N., 2° 0′ E.; x., 61° 38′ N., 0° 33′ E.; xi., 61° 50′ N., 1° 0′ W.; xii., 61° 0′ N., 1° 18′ W.; xiii., 61° 10′ N., 2° 9′ W.; xiv., 61° 23′ N., 3° 25′ W.; xv., 61° 38′ N., 4° 39′ W.; xvi., 61° 44′ N., 6° 3′ W.; xvii., 61° 13′ N., 6° 34′ W.; xviii., 60° 53′ N., 5° 30′ W.; xix., 60° 35′ N., 4° 26′ W.; xx., 60° 13′ N., 3° 9′ W.; xxi., 59° 40′ N., 1° 15′ W.; xxii., 59° 32′ N., 0° 2′ E.; xxiv., 58° 53′ N., 0° 25′ W.

To take first the surface-temperatures. These fluctuated much in the first part of the course from the entrance of the Moray Firth to Lerwick. Starting at 7°·5, the temperature rose opposite the Pentland Firth to 8°·8, fell off the Orkneys to 6°·6, rose again in the neighbourhood of Fair Isle to 9°·3, and after falling as low as 5°·4, rose to 8°·4 at Lerwick. Similar temperatures (8°·3–8°·5) were then met with as far as Station vii., after which point there was a rapid rise to 9°·6, followed by an exceedingly sudden drop to 6°·6 (the salinity dropping from about 35°·3 to 32°·6) near Station viii., off the Norwegian coast. Running westward, temperatures ranged in the neighbourhood of 9°·5 all the way to the middle of the Faeroe Channel, and then dropped between Stations xiv. and xv. to 7° at the latter point. They rose again as Faeroe was approached, to 8° or a little less; and on the homeward and more southerly course, a colder current was again crossed, this time in a broader and apparently double belt, between 4° and 5° W. longitude, with temperatures of 6°·6 to 6°·8. Eastward of 4° W., a rapid rise took place to 8°·9, rising further to 9°·4 a little to the east of 3°, and thereafter the curve fell, with considerable fluctuations, to about 8° at the limit of Station xxii. (0° 2″ E.).

Passing to the deep-water temperatures, we have, on the line from the Moray Firth to Lerwick (Stations ii., iv. and xxi.), everywhere warmer underlying colder water, the readings at 0 and 100 metres being respectively 8°·2–8°·8, 8°·8–9° and 8°–8°·6.

Between Lerwick and the coast of Norway, we have firstly at Station vi. slightly irregular readings, falling from 8°·5 at the surface to 8°·2 at 130 m.; at Station vii., the surface-water of 8°·3 has underneath it warmer water to 8°·85 at 60 m., cooling to 8°·65 at 140 m.; while at Station viii., a broad zone of similarly warm water underlies the very cold (6°·7) surface-layer (6°·05 at 20 m.), giving us readings of 8°·3 at 100 m., 8°·7 at 200 m., below which level the temperature falls again to 6°·0, at 380 m., near the bottom. Turning westward, we have at Station ix.

practically the warmer waters of Station viii., released from the superincumbent colder layer; that is to say, we have at 20 m. 8°·6, at 100 m. 8°·4, at 200 m. 7°·85 and at 300 m. 6°·91. At Stations x. and xi., the water cools very slowly downwards, from 9°·6 to 8°·8 at 170 m. and from 9°·3 to 7°·8 at 360 m., respectively. At Station xii., in shallower water, we have readings to 100 m., practically identical with those to the same depth at Station xi., further to the north.

The records along the next two lines, those crossing the Faeroe Channel, deserve to be given in detail.

Faeroe to Shetland (xvi.–xii.)

400		6·9	0·5			
500		1·62	−0·25			
600		1·72				

The first of these two tables corresponds as closely as possible with that given by Mr. Helland-Hansen for the August cruise in the note to NATURE already quoted. The most striking differences will be found to be that below 300 metres the temperature is now much higher at Station xiv., and at 400 m. it is now much lower at the more westerly Station xv. This means that the cold wedge is now considerably further to the westward and probably also of less vertical extent. In the more southerly section (Table II.), the cold wedge is seen, of great intensity, at Station xix. It is to be regretted that the next station (xx.) to the eastward of xix. is a shallow-water one, and still more to be regretted that we have no deep-water station to the westward of Station xv.

I have hastened to publish these few preliminary notes in the belief that many are interested in the progress of the work, and because we shall have long to wait until the full data are available and the final deductions are drawn by competent hands.

D'ARCY W. THOMPSON.

Dundee, December 29, 1902.

The Quadrantids of 1903.

OBSERVATIONS were made at Hampstead Heath on January 1, 3 and 4 for the Quadrantid meteors. During a combined watch of six hours, 57 meteors were seen, distributed thus:—

		h. m. h.		
Jan. 1	...	11 55 to 14	...	18 meteors
3	...	14 0 to 16	...	29 ,,
4	...	15 0 to 17	...	10 ,,
		Total	...	57

The paths of 10 only were registered, which I append as follows:—

25 Holford Square, Percy Circus, W.C., January 11.

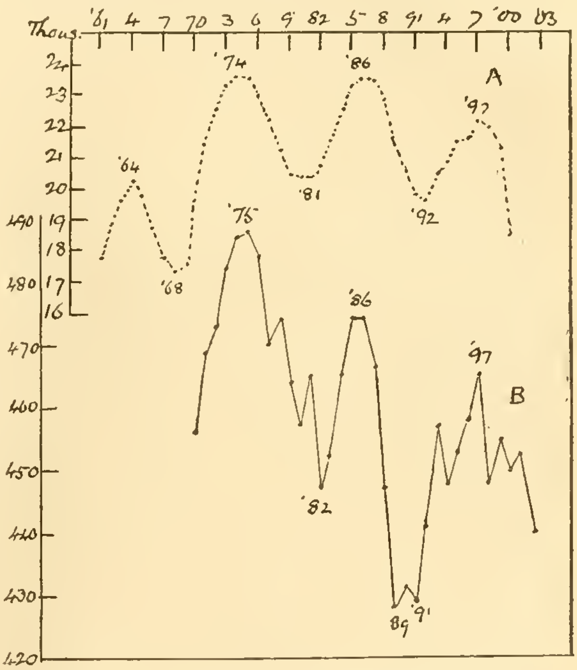
G. MCKENZIE KNIGHT.

[1] A short pathed meteor.

Sun-spots and Summer Heat.

Is not a connection between these rather distinctly suggested by the enclosed curves?

A is obtained from sums of the sun-spot figures (mean daily area) in the thirty years ending 1861, '62, '63, &c.



B is from sums of the number of days with maximum temperature over 80° in the thirty years ending 1870, '71, '72, &c.

ALEX. B. MACDOWALL.

4 Bodfor Terrace, Aberdovey, Wales, January 5.

A Curious Projectile Force.

HAVE you or any of your readers had an experience similar to this? I placed a half bottle of champagne, *half full*, in a basin in a lavatory, with cold water tap dripping in same, corked. About twenty-four hours later we heard a crash, and found that the bottle had literally jumped out of the basin through the window and out into the garden, breaking itself on the stone work beneath window. Now I know there would be nothing remarkable in a bottle bursting, but in this case not a particle of glass was found in the room, and the hole in the window-pane being so clean cut shows enormous velocity. The wine was a good brand and of the year 1892. A scientific friend tells me the facts are so unaccountable that I thought I would venture to trespass on your space.

B.A. OXON.

THE HEWITT MERCURY LAMP AND STATIC CONVERTER.

ONE of those happy discoveries which at once and unexpectedly supply the solution of a difficult or hopeless problem was brought to the notice of a limited number of railway and of scientific men last Friday evening by Mr. George Westinghouse. The company were invited to meet Mr. Westinghouse at the Westinghouse Company's office in Norfolk Street, Strand, to see two of the inventions of Mr. Peter Cooper Hewitt, of New York, and to meet again at Claridge's Hotel, after an hour, in circumstances that would enable them more easily to contemplate the full beauty of what they had seen.

The mercury vapour lamp consists of a long vacuum tube, perhaps a yard long and an inch in diameter, but of dimensions depending on the current and potential available and the light required, with an electrode at each end, but at the lower end, which is the negative pole, the tube is blown out into a bulb, which contains a quantity of mercury. When the ordinary voltage of a house supply is applied to the terminals, nothing happens at all, as it is not sufficient to break across the long, vacuous gap. If, however, a single spark from an induction coil is sent from one terminal to the other, the current from the house mains is immediately started and continues to pass indefinitely, producing a brilliant light absolutely without flicker, but of a ghastly hue. It is a splendid and economical light, requiring, according to the information furnished, only half a watt, or under favourable conditions only one-third of a watt, to the spherical candle-power, whereas ordinary incandescent lamps require about four watts to the candle-power. It is a beautiful light to work by so long as colour is not a point—for instance, for engineers' drawing or for lathe and machine-shop work—as the extent of the luminous surface does away with the glare and the contrast of sharp shadows cast by lamps of small surface. It is, no doubt, valuable for lots of things, and there is nothing to wear out. But the colour! It is not like the sodium light, practically monochromatic, so that all colour difference is abolished and everything becomes black or yellow or something between the two. That is merely hideous. Here, however, there is plenty of colour. The spectrum shows two bright orange lines, a green line, a pale greenish-blue line and a dazzling blue line, but no red. The result is that flowers and coloured articles appear wonderfully coloured, but not with their own natural colours, and what any pigment will look like no one can tell, nor can the faintest idea be formed of what the colour of anything seen by the light of the Hewitt lamp really is. The light plays such pranks with colour that the colour sense seems to have gone crazy. One red thing will appear blue, another black, one blue thing blue, another brown, but the skin becomes ghastly. If anyone sees himself in a glass, it is difficult for him not to form a sort of opinion that he is killed and drowned and dead as well. These effects the Westinghouse people believe may somewhat interfere with the success of the lamp as a domestic luminary. But even here there are possibilities. A wisp of silk dyed with a particular crimson dye appears to have its colour enhanced. It shines with a glorious luminosity among its surroundings, on which not a trace of a rosy tone can be discovered. This is a true fluorescence. If a spectroscope be turned on the lamp or any ordinary thing lighted by it, the red end of the spectrum is absent, but when this particular dye is brought up, the whole of the red end flashes out, and other things may be seen more as they are. A striking experiment is to look at the lamp through ruby glass, through which hardly any light can be detected, and then to bring up the dyed silk, which immediately appears to create its own light and shine brilliantly.

Enough has now been said to give an idea of the Hewitt lamp, which is found to have the remarkable property, one not unknown as a vacuum phenomenon, of only allowing a current to pass in one direction, that being with the mercury as a negative pole. If it is attempted to send a common alternating current through a Hewitt lamp, it may be started by a preliminary spark, but at the first reversal it goes out, and so it has to be started perhaps a hundred times a second to keep it going. If, however, the three ends of a star-wound triphase transformer or generator are connected with three electrodes near the top of a globe and the common centre is connected with the mercury pole at the bottom, then, as before, nothing will happen until a starting spark has been sent across the globe, for which purpose a fifth electrode is placed at the top; then at once the triphase current starts running round from electrode to electrode, and always going to the mercury below, and each current being still alive when the next is ready to start, they keep each other going and a single direct current leaves the mercury electrode. By this simple means, it is possible to rectify a current of even 1000 volts, subject, however, to a constant loss of 14 volts in the bulb, and this whatever the voltage. As the contrivance will work with anything between 100 and 1000 volts, and at present up to 100 amperes, it will be evident that if further experience bears out the information so far available, the present methods of conversion depending on the use of rotary converters and motor generators will be at an end, and the labours and ingenuity of Mr. Pollak and others with the aluminium cell largely superseded. With the higher voltage, the economy is unapproached by other methods, the loss being only 1·4 per cent., which appears as heat in the bulb.

C. V. B

THE VIBRATIONS OF GUN BARRELS.

A SERIES of experiments has been conducted by Messrs. C. Cranz and K. R. Koch for the purpose of obtaining information respecting the character of the vibrations set up in the barrel when a gun is fired. It is a matter of experience that when a cylindrical rod is struck by an approximately axial blow, the particles of the rod, instead of vibrating in straight lines, perform in general elliptic vibrations the axes of which vary in direction at different points, and it was one of the objects of the investigation to ascertain how far a gun barrel behaved in the same manner.

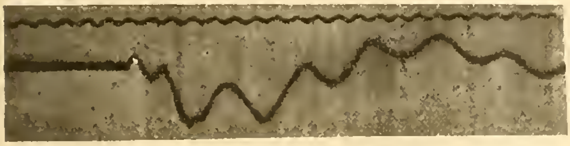
For this purpose, a number of military rifles supplied by the firm of Mauser were furnished with projecting wires the motions of the shadows of which, thrown on a screen by a powerful lens, were recorded by photography, a tuning-fork similarly projected affording a standard of comparison from which the period of vibration could be measured.

The rifles were either fixed in a support of cork or held in the position usually adopted by marksmen, under conditions closely resembling those existing in actual rifle practice. By means of an electric spark, a mark was recorded on the photographic plate indicating the exact instant at which the projectile left the barrel.

An example of the diagrams obtained is shown by Fig. 1 for a rifle fixed in cork and by Fig. 2 for free firing. It will be observed that under the latter conditions a dark shadow is in general produced by the recoil of the rifle, and it is only possible to study such parts of the vibration curves as are not blotted out by this shadow.

The experiments show that the vibrations are in general, as predicted, elliptic in character, each vibrating particle describing a small ellipse instead of a straight line. The vibrations are generally similar to those of an elastic rod fixed at one end, and consist of a fundamental tone and overtones, of which as many as three have been

observed. From the tabulated results, it appears that the periods of vibration for the fundamental and first two overtones, while varying considerably for different rifles, may be said to be roughly about 0·04, 0·008 and 0·002 of a second, and the first two overtones are those the periods of which have been the most completely determined. In the case of the other vibrations, most of the tabulated results contain the mere indication that they have been observed, from which it is a natural inference of the reader that they have been much less intense, a result

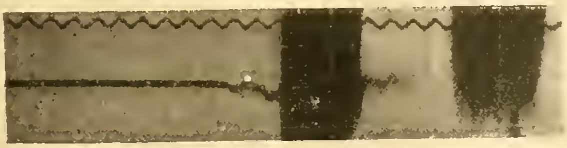


γ

FIG. 1.—10-Millimetre Servian rifle, right-handed breech, fixed in cork.

which appears on general grounds highly probable. The nodal points of the overtone appear to a certain extent to vary periodically in position. The vertex of the angle of vibration, instead of being at the screw of the breech pin, as commonly assumed, is at a nodal point near the muzzle, a result arising from the effect of one of the overtones at the instant when the bullet leaves the gun, and as the overtones predominate, the vertex approaches the muzzle.

Of practical interest is the conclusion that, since a certain time elapses before the vibrations are completely

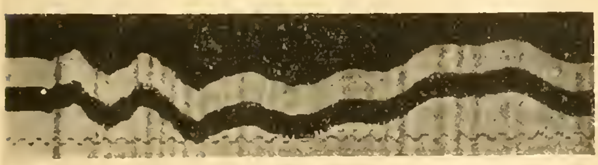


γ

FIG. 2.—11-Millimetre Mauser held as in rifle practice. The white spot γ, indicates the instant of the bullet leaving the barrel.

formed, it is important that the bullet should leave the muzzle before the deflection of the barrel has become considerable, and hence that a small-bore gun is to be preferred to one of large calibre. In the six-millimetre Mauser gun, it would appear, from the position of the white dot in Fig. 3, that the limit in this direction has practically been attained, so far as horizontal vibrations are concerned.

Two further points are discussed. The effect of the breech has been observed by comparing guns with a right-handed and left-handed breech respectively. In



γ

FIG. 3.—6-Millimetre Mauser rifle, fixed in cork.

the former, a deviation to the right of 7mm. per 4·5 metres was observed, in the latter, a deviation to the left of 4 mm. in the same distance.

The other question arises in connection with the attachment of bayonets. In some observations of the horizontal vibrations, a rifle of 11 mm. calibre was experimented on, with the bayonet attached at one side, the lateral attachment being the best calculated to affect these particular vibrations. The effect was to increase the periods of the first overtone from 0·0095 to 0·0130 of a second and of the second from 0·0016 to 0·0036 of a second, to give rise to a third overtone of period 0·0011 of a second and also to alter the phase at the instant at which the bullet left the muzzle.

The paper of which this is a brief summary is published in the *Abhandlungen* of the Bavarian Academy (cl. 2, vol. xxi. part iii., pp. 559–574), and it will be seen that it has an important bearing on rifle shooting generally. A marksman who is fully aware of the nature of the vibrations occurring in his rifle ought to be able to allow for them, with a little practice, far better than one ignorant of the scientific aspect of the question.

G. H. BRYAN.

PROF. JOHN YOUNG.

JOHN YOUNG was born in Edinburgh in 1835. He was educated at the High School and at the University, and finally he graduated as doctor of medicine. Like many of his time, he came under the spell of the great teachers who then made the northern university famous, such men as Goodsir, Edward Forbes, Christison, Syme and Simpson, and there is reason to believe that in particular the first two gave a scientific bias to Dr. Young's career. For some time he worked on the staff of the Ordnance Survey and made a friend of Sir Roderick Murchison, then a leader in the geological world. This was followed by his appointment to the chair of natural history in the University of Glasgow in 1866, and in this chair he taught both zoology and geology for nearly thirty-five years. After a period of failing health, he died on December 13, 1902. Such, in brief, is an outline of his career, but those who knew Dr. Young will recognise how imperfect a representation it is of the man's personality. Gifted with a keen and penetrating intellect and a fertile imagination, showing versatility of acquirements rarely met with, absolutely unconventional, he was also a man of untiring and restless energy. He was a scholar in a high sense of the term, he possessed a cultivated and pure literary taste, he was an artist facile both with brush and pencil, and he had a wide and critical taste in music. As keeper of the Hunterian Museum, he acquired much knowledge of rare books and manuscripts, of the great collection of coins and medals to be found there, and of works of art. Wide, however, as was the sphere of his activity in the University, he yet found time for active labours in the cause of female education, in the work of the Technical College, and in the municipal and social life of the city of Glasgow. It was this versatility and superabundant energy that hindered Dr. Young from doing the amount of original work in the two sciences of zoology and geology which might have been expected from a man of his genius, and the work of his life must not be judged from this point of view. His chief labour, perhaps, was the systematic arrangement of the great legacy of William Hunter—books, pictures, medals, engravings, coins—and in this work he took a keen delight and over it he spent laborious hours, even far on into the night when silence reigned in the cloisters. But it was the man's individuality of character that made him a force in his time. Often a determined opponent, he could also be a true friend, while his mental moods, sometimes quiet and observant, ofttimes brilliant and radiant with flashes of wit and humour, constrained even those who knew him best to regard him as a man quite by himself. He has thus left little of an enduring character in the literature of science, but he will be long remembered by many generations of students in the University of Glasgow.

JOHN G. MCKENDRICK.

JAMES WIMSHURST, F.R.S.

WE regret to have to announce the death of Mr. James Wimshurst, F.R.S., which occurred at his residence on Saturday, January 3. Mr. Wimshurst was born in London in 1832 and was therefore in his seventy-first year. He was for a long time a surveyor with Lloyds', both in London and in Liverpool, finally becoming principal shipwright surveyor to the Board of Trade, which appointment he held until a few years ago, when he retired under the age rule.

Mr. Wimshurst was devoted to scientific pursuits, in which he spent the greater part of his spare time. At his private house at Clapham, he had a laboratory and workshop, which he had himself fitted up with the assistance of his two sons. It was here that he worked out the new designs in influence machines which have made his name familiar to every student of science. His attention was first turned to this subject about 1881, when he constructed a machine of the Holtz pattern, but embodying several important improvements. After about a year's work, he designed an influence machine with oppositely rotating glass discs bearing metal sectors on their outer faces, which he called a "duplex" machine, but which has been universally known since as "Wimshurst's machine." For many years, he continued perfecting this pattern of electrostatic generator, building larger and more efficient machines. These machines have displaced all other generators of static electricity on account of their possessing the property of being self-exciting under any atmospheric conditions; they are very largely used for experimental, X-ray and electromedical works.

In 1890, Mr. Wimshurst designed a machine capable of producing rapidly alternating charges of electricity. In the same year, he was elected a member of the council of the Physical Society. In 1898, he was elected a fellow of the Royal Society; he was in addition a member of many other scientific societies, including the Institution of Electrical Engineers and the Röntgen Society; he was also a member of the board of managers of the Royal Institution.

All Mr. Wimshurst's scientific research was done for pure love of the work, and he persistently refused to accept any pecuniary benefit from it. His advice and assistance were always at the service of those interested, and his long experience with influence machines made his advice invaluable and in frequent requisition.

NOTES.

WE are authorised by Prof. J. J. Thomson to contradict the announcement that he has accepted the chair of physics in Columbia University, U.S.A.

THE Geological Society of London will this year award its medals and prize funds as follows:—Wollaston medal to Prof. Heinrich Rosenbusch, of Heidelberg, Murchison medal to Dr. C. Calloway, Lyell medal to Mr. F. W. Rudler, Bigsby medal to Dr. H. M. Ami, of Ottawa, Prestwich medal to the Right Hon. Lord Avebury, Wollaston fund to Mr. L. L. Belinfante, Murchison fund to Mrs. Gray, and Lyell fund to Mr. George Edward Dibley and Mr. S. S. Buckman.

IN a letter to Wednesday's *Times*, Sir Norman Lockyer states that several months ago he discussed with Mr. Shaw, the secretary of the Meteorological Council, the desirability of obtaining information regarding barometric pressures from ships crossing the Atlantic, by utilising wireless telegraphy. It now seems probable that this idea will soon be practically realised, for in reply to an ethergram from Mr. Marconi, Sir Norman Lockyer asked for help in this matter, and on January 13 received the following message:—"By wireless telegraphy.—Thanks for suggestion, hope to be able to do so soon, big westerly gale here Monday.—MARCONI." Sir Norman remarks that all friends of Science will be grateful to Mr. Marconi for such generous and invaluable assistance which will undoubtedly be of enormous advantage to British meteorology.

THE article by Dr. J. C. McVail in another part of this issue (p. 254) directs attention to the present unsatisfactory position of the law relating to vaccination in England, and the need for educating and organising public opinion in support of a new Vaccination Act. At the end of the present year, the Vaccination Act of 1898 will have run its experimental course of five years, and the opportunity should then be taken to ensure the introduction of a new measure based upon scientific principles. It is to render assistance in this direction that the Imperial Vaccination League has been formed. A deputation of the League is to wait upon the President of the Local Government Board this week, and will place before him the principal points upon which legislation is needed in connection with vaccination, with particular reference to revaccination. Three sub-committees appointed recently by the League have reported upon the degree of immunity given by primary vaccination, the need for revaccination at the age of twelve years, the transfer of vaccination administration from Boards of Guardians to some authority charged with public health functions, and the preparation and supply of calf lymph. The deputation which will wait upon Mr. Long will doubtless refer to the conclusions of the sub-committees and will urge emphatically that legislation should tend in the direction suggested by them.

WE regret to announce the death of the Rev. Dr. H. W. Watson, F.R.S., author of standard works on mathematical and physical subjects, and of well-known treatises on the kinetic theory of gases.

WE notice with regret the announcement of the death of Dr. H. E. Schunck, F.R.S., distinguished by his researches in connection with the chemistry of colouring matters.

THE death is announced of M. Albert Hénocque, vice-president of the Paris Biological Society and assistant director of the laboratory of biological physics in the Collège de France. M. Hénocque was known for his work in connection with the spectroscopic examination of blood.

THE King of Sweden and Norway has, *La Nature* reports, conferred the Norwegian medal Til Beleenning (Pour le mérite) upon M. Berthelot in recognition of the work of the distinguished French chemist.

A REUTER telegram from Ashkabad states that a fresh earthquake occurred at Andijan at 11 a.m. on January 7. The shock was of a particularly violent character.

THE Royal Statistical Society has awarded a Guy medal in silver to Mr. R. H. Hooker, for his paper on the suspension of the Berlin Produce Exchange and its effect on corn prices, which was read before the Society on December 17, 1901.

LAFFAN'S AGENCY announces from New York that Mr. Henry Phipps has just given 250,000*l.* for the establishment of a hospital at Philadelphia for the study, treatment and prevention of tuberculosis. The Pasteur Institute in Paris will be the model for the new establishment, which, however, is to devote itself exclusively to tuberculosis.

AN International Fire Prevention Congress will be held in London on July 7–10 in connection with the International Fire Exhibition at Earl's Court.

THE *Times* correspondent at St. Johns reports that Lieutenant Peary has decided to make another attempt to reach the North Pole. He is looking for a suitable steamer for a voyage next summer.

A GENERAL exhibition, devoted to hygienic milk supply in all its branches, will be held at Hamburg on May 2–10, 1903. Applications by intending exhibitors should be made, not later than February 15, to the Geschafftstelle, 46, Kampstrasse, Hamburg.

THE Carnegie Institution has, says *Science*, granted 1600 dollars to Prof. E. W. Scripture, of Yale University, for the prosecution of researches on the voice; 5000 dollars to Prof. W. O. Atwater, for his work with the respiration calorimeter, and has also made grants, the amount of which is not reported, to the Peabody Museum of Yale University, and to send Dr. H. S. Conrad, of the University of Pennsylvania, to Europe to study varieties of the water-lily.

AN exhibition is being held in London of the results of what is described as a new process for the preservation of animal tissues, by the injection of a fluid, the composition of which is not made public. The process is said to afford a satisfactory method of embalming animal bodies and of preserving museum specimens in a condition closely resembling life. The period which has elapsed since the application of the process to the various preparations exhibited is said by the inventor to range from a few weeks to thirty years.

A WRITER in the *Times* of January 7 suggests that wireless telegraphy should be used for sending time-signals from Greenwich and other places at definite instants, so that they could provide a means of determining longitude on ships having instruments capable of detecting the signals, or for regulating clocks or chronometers. The same suggestion was made by Mr. John Munro in NATURE of August 28, 1902 (vol. lxvi. p. 416), and the idea has doubtless occurred to others. Another writer, in Saturday's *Times*, suggests that some steamers crossing the Atlantic should be equipped with instruments for sending wireless messages as to meteorological conditions in mid-ocean, so as to provide material for weather forecasts and warnings.

REUTER'S AGENCY announces that the British and German Governments have decided on the immediate dispatch to West Africa of a mixed commission to demarcate the boundaries laid down by the Anglo-German Agreement of 1893. The frontier which is now to be fixed is that from the southern shore of Lake Chad to Yola, a distance of some 300 miles. The commissioners will proceed up the Benue direct to Yola, where they hope to arrive by the end of March, and will then work their way along the frontier to Lake Chad and, after fixing the position of Kuka, will return by the same route. The work is expected to occupy about a year.

WE learn from the *Lancet* that Dr. Michael Grabham, of Jamaica, a zealous exponent of the West Indian Culicidæ, is at work upon the mosquitoes of the Atlantic islands and has already obtained interesting results. The Azores have yielded no specific forms of any interest, but from the Madeiras he has sent to the British Museum four or five new varieties of culex in addition to one or two already well known and described. Dr. Grabham has found at Teneriffe, on the south side, a small anopheles identical with, or allied to, the malarial insect of the west coast of Africa. He has found also the same mosquito as is concerned in the spread of yellow fever at Havana.

N a letter from Dr. Logan Taylor, the leader of the Sierra Leone expedition of the Liverpool School of Tropical Medicine, reference is made to the progress of the expedition in Sierra Leone. A very decided absence of anopheles larvæ in places where it was formerly easy to get any number has been noticed, and is due to their not being able to breed owing to the pools being either swept out or oiled regularly. Compared with the corresponding time last year, in some of the notoriously bad streets, where in a single house as many as six, seven or a dozen anopheles mosquitoes could be found in the early morning, this year, after searching house after house with great difficulty, one, or perhaps two, adult insects alone were discovered. Since the members of the Liverpool School expedition stopped clearing up yards and emptying out the water containing culex larvæ, no one else has taken up the work, and these insects are getting bad again, and unless the Government or the school will keep on the work, the money the school has spent on it will be almost thrown away.

THE copy of Sowerby's "English Botany" Supplement in the library of the Royal Botanic Gardens, Kew, is incomplete, wanting plates 2912 to 2960, with letterpress and index, also plates, with letterpress, 2964, 2977, 2978, 2983, 2987, 2988 to 2999. The director appeals to the public to assist him in completing this classical work on British botany, either by presentation or sale.

A NEWLY issued part of the "Conspectus Faunæ Grönlandicæ," which is now being prepared by the naturalists of Copenhagen, relates to the mammals, and has been written by Mr. Herluf Winge. The known mammals of Greenland are stated to be thirty in number, but sixteen of these are Cetaceans. On land there are two rodents (the polar hare and the lemming) and two ungulates (the reindeer and the musk-ox) found in Greenland, but the remaining ten are all Carnivores, of which four only are terrestrial and six are marine, *i.e.* seals. The four terrestrial mammals are the Arctic fox, the wolf, the polar bear and the stoat or ermine.

IN the *Sitzungsberichte der niederrheinischen Gesellschaft* (Bonn), Herr Constantin Koenen discusses the age of the human remains of the Neanderthal. The first of these, known as "Homo neanderthalensis I.," is referred to the second epoch of the Quaternary Palæolithic period, or "Moustèr's epoch," and the second form, "Homo neanderthalensis II.," to a somewhat later period.

MR. LOUIS BEVIER'S paper on the vowel I (as in pique), forming one of a series of papers on the various vowel sounds in the *Physical Review*, leads to the conclusion that the sound of I is characterised by a powerfully reinforced upper partial at some pitch generally lying between 1900 and 2500, usually nearest the value 2560, a chord tone which is generally present with a much larger amplitude than for the more open vowels, and beyond these two tones comparatively little intermediate resonance. The latter peculiarity seems to give the vowel its peculiar thin tone. It appears that the American I is more open than the German, and its characteristic upper partial lower pitched. The author proposes to present, in the course of time, similar studies on the labio-guttural vowels from A to U.

IN the Cracow *Bulletin*, No. 8, Dr. Ladislaus Natanson discusses from a mathematical standpoint the problem of the deformation of a thin cylindrical disc of plastico-viscous material under the action of normal pressure on its opposite faces. The investigation bears directly on Von Obermeyer's experiments. In connection with the question as to how far a plastic solid is representable as a viscous fluid, an interesting idea is introduced. If we imagine it possible for the pressure on the disc to be varied in such a way as to maintain the disc of constant thickness, then, according to the theory considered by Dr. Natanson, the pressure would be an exponential function of the time, the modulus of decay and therefore also the time of relaxation being finite. For a viscous liquid, on the other hand, the time of relaxation vanishes. From experiments such as those of Von Obermeyer, Dr. Natanson considers it possible to determine both the "coefficient of internal friction" and the time of relaxation.

IN the third part of the *Beitrage zur Psychologie und Philosophie*, Dr. Götz Martius gives a detailed investigation on the duration of light sensations. It is pointed out that "Talbot's Law," while defining the limits within which intermittent sources of light give rise to a uniform light-sensation of mean intensity, gives no information as to the actual duration of the light-sensation itself. Dr. Martius, after describing an apparatus used by Prof. Exner, gives an account by Karl Minnemann of a new light interrupter. It appears that the time which elapses before the sensation is a maximum depends on the intensity of the stimulus, decreasing in general as the intensity increases, while the duration of the sensation depends both on the intensity and on the duration of the stimulus. A discussion of the bearing of the actual results on kindred investigations such as those of Charpentier and Shelford Bidwell is noteworthy.

A SOMEWHAT remarkable attempt to trace points in common between such apparently different subjects as biology and education is made by Prof. Leopoldo Maggi, writing in the Lombardy *Rendiconti* in a paper entitled "Tachygenesis and University Studies." Both in the vegetable and animal kingdoms, it is pointed out that in the transition from the lower to the higher forms there is a continuous acceleration in the development of maturity, and this law of embryonic acceleration, which, following E. Perrier, the author describes as Tachygenesis, is an inevitable consequence of the struggle for existence. The same laws may be applied to social life, and it is suggested that they tend to bring about a reduction of the time given to university study in the lifetime of a man, but against this tendency there is the at present insuperable barrier opposed by regulations which fix the number of years required to complete the university courses. The new university regulations in Italy have reduced the minimum number of lectures in any course from about seventy to fifty, and this the author considers a good reason for reducing the length of the qualifying period for the university degrees. Prof. Maggi suggests several other applications of biological principles to allied social problems.

AN interesting article on the transmission of vision to a distance by electricity is contributed by Lieut. J. H. Coblyn to *L'Éclairage Électrique* for December 27. The author reviews briefly the theoretical aspect of the subject and the attempts which have been made at its practical solution. He suggests that some less sluggish transmitter than a selenium cell may have to be sought before satisfactory results are obtained, and as receiver proposes the use of a Blondel oscillograph, the moving part consisting of a tube which, as it is deflected, cuts off more or less of the light from a source of constant intensity. This is a modification of the method of Ayrton and Perry; another method proposed by M. Weiller is to use a sensitive flame the intensity of which is varied by a telephone diaphragm actuated by the transmitted current. In addition to the problem of reproducing the intensity of the illumination, a satisfactory solution has to be found to the difficulty of exploring the object and image synchronously at transmitting and receiving stations as the whole surface has to be covered in less than one-tenth of a second, the time of duration of the retinal impression. The author concludes that the problem is still surrounded with great difficulties.

Symons's Meteorological Magazine for December last contains a climatological table for the British Empire for 1901, so far as it can be shown by nineteen representative stations, but it is not claimed that the records quoted furnish more than a few useful samples of the various climates included in the British dominions. The highest temperature in the shade was 110° at Adelaide, in February. A new station has been included, viz. Dawson, where a temperature of −50° in the shade was recorded in December, but the observations are incomplete. The highest mean temperature was 82°·1 at Colombo, and the lowest 36°·4 at Winnipeg. The driest station was Adelaide, mean humidity 59°, and the dampest Colombo, mean humidity 82°. The highest temperature in the sun was 168°, at Trinidad. The greatest rainfall was 114 inches, at Lagos, and the least 18 inches, at Adelaide. None of the extremes referred to can claim distinction as "records," but at individual stations the sun temperatures at London, 139°·8, and at Malta, 162°·9, are the highest observed there, and at London the number of rainy days, 128, is the lowest since these interesting tables were commenced.

THE latest issues of the *Bulletin* of the Entomological Division of the U.S. Department of Agriculture include the *Proceedings* of the fourteenth annual meeting of the Association of Economic Entomologists and some miscellaneous results of the work of the division. In the former, attention is called to the magnitude of the injuries inflicted by insects on the forests and forest-products of the United States, and the crude condition of our knowledge relating to the life-history of the insects in question. It is urged, therefore, that the work of the division is one of great and increasing importance.

THE first part of vol. vii. of the *Anales* of the National Museum of Buenos Aires contains a memoir, with portrait, of the late Dr. C. Berg by Señor A. Gallardo. In the same issue, Señor A. Mercerat describes a very imperfect skull of a toxodont from the pampean formation of Azul, which is regarded as representing a new genus and species, under the name of *Carolibergia azulensis*.

WE have received from the director, Captain S. S. Flower, a copy of a handy little guide (with plan) to the Zoological Gardens at Giza, near Cairo. The general introduction is written in English, French and German, and the names of the animals are given in several languages. The issue of this guide may be taken as an indication that the institution under Captain Flower's charge is in a satisfactory and progressive condition.

THE latest issue, vol. lxxiii. part i., of the *Zeitschrift für wissenschaftliche Zoologie* contains three papers, all of a highly technical nature. In the first, Herr Max Abel treats of regeneration among the oligochætous worms; in the second, Herr J. Müller discusses our knowledge of the land planarians of the family Bipaliidæ; while in the third, Herr K. Hann describes the development of the common hydromedusan *Clava squamata*.

IN the December number of the *Zoologist*, Mr. F. Coburn describes and figures a specimen of the British wild goose named *Anser paludosus* by Strickland in 1858. The type of that form has been generally regarded as an old male of the bean-goose (*A. segetum*); but a specimen obtained in 1896 by him at St. Abb's Head, Scotland, leads Mr. Coburn to conclude that it is a perfectly valid species, characterised by its large size, long neck and large feet, as well as by its aquatic habits. Apparently the bird was well known to the Yorkshire "carr-men" and "marsh-men" half a century ago, but no examples are known to science save the type and the one procured by Mr. Coburn. Where can be the habitat of this apparently distinct species is now the question.

THE first three parts of the second volume of the *Records* of the Botanical Survey of India have been issued. Mr. J. J. Wood has compiled a list of plants mainly from the province of Chutiá Nagpur. This part includes a map of the district and two sectional diagrams. Mr. Gammie has recorded the results of his investigations into plants used during periods of drought. For the purpose of making bread, seeds of species of Indigofera,

Cyanotis and Panicum are used. Other sources of nourishment are the leaves of Amarantus, Rivea and Leptadenia. A systematic enumeration of the species of Calamus and Dæmonorops, by Mr. O. Beccari, is based mostly on plants growing in the Malayan Peninsula and the adjacent islands, and only a few species belong to India or Ceylon.

An addition to our knowledge of semiparasitic plants is made by Mr. S. Kusano, who contributes the result of his studies on *Buckleya quadriala*, a genus of the Santalaceæ, to the *Journal* of the College of Science, Tokio. The plant was found growing naturally on several hosts, some Dicotyledons and some Gymnosperms, but a decided preference and better development was displayed on the roots of Abies and Cryptomeria. The haustoria arise laterally in the young stage, but eventually appear to originate from the apex, or in reality in close proximity to the apex. A feature which has only been suggested for allied genera, *e.g.* secondary growth due to cambium, is in Buckleya so marked that the contour of the vascular strand is entirely changed and definite medullary layers become differentiated. Since the cambiums are adjacent and develop tissue to the same degree, the sucker keeps pace with the growth of the host root.

A brief critical review of the theories relating to plant evolution, more particularly the origin of new forms, is offered by Prof. Schwendener in a recent number of the *Naturwissenschaftliche Wochenschrift*. The article touches upon the origin of species by natural selection, the variations developed as special adaptations due to environment, the mutation theory and incidentally the production of hybrids. The arduous experimental work of De Vries and the possibilities of mutation or heterogenesis are acknowledged and accepted, but the opinion is expressed that new forms have not all originated after the same manner and that the direct action of external conditions has undoubtedly played an important part in the production of new and the modification of acquired characters. Prof. Schwendener is in accord with Darwin's theory of selection so far as it is limited to the origin of cultivated races of plants and to the breeding of domesticated animals, but does not believe in its application under natural conditions. This view, which coincides with the expressions of other eminent German botanists, naturally tends to diminish the importance previously attached to the theory of natural selection, but the writer pays just tribute to the value of Darwin's work, "whose service it was," he says, "to set on a new foundation the doctrine of descent, and after a struggle which was victoriously pursued to establish the idea permanently in biological science."

Prof. F. Frech contributes to the *Zeitschrift der Gesellschaft für Erdkunde* (Nos. 7 and 8) a series of studies of the climates of past geological times. He accepts the views of Arrhenius with regard to the effect of variations in the amount of carbonic acid gas in the atmosphere, and considers the changes in the distribution of land and sea as the factor of next importance. The review of the geological evidence is interesting and important, but the author hardly gives sufficient prominence to physical aspects of the question, especially the effect of changes of temperature distribution on the atmospheric circulation and the influence of oceanic currents upon climate. The maps of continents and seas at the end of the Carboniferous period and of Europe during the Glacial period are valuable.

Two more volumes of the excellent *Scientia* series of scientific monographs published in Paris by M. C. Naud have reached us, viz., "Le leucocyte et ses granulations," by Dr. C. Levaditi, and "Les phénomènes des métamorphoses internes," by Dr. J. Anglas. The volumes fully maintain the high character of preceding books in this series.

The Orient Steam Navigation Company announce the commencement of their 1903 season of pleasure cruises. No. 1 cruise, starting February 26, is to the Riviera and on to Palestine, calling *en route* at Tangier, Palma, Sicily, Crete and Cyprus, returning home by way of Alexandria, Naples, Algiers and Gibraltar. The second cruise, leaving London March 14, is to Tangier, Malaga, Nice, Palermo, Crete, Smyrna and Constantinople, visiting on the return voyage the Piræus (for Athens), Nauplia, Katakolo (for Olympia), Naples, Algiers and Gibraltar.

The reversible transformation of ammonium thiocyanate into thiourea has recently been investigated on a large scale by Reynolds and Werner, who give an account of their experiments in the *Journal* of the Chemical Society. At temperatures from 170°–180° C., the fused product obtained by heating either ammonium thiocyanate or thiourea for a sufficient time consists of 75 per cent. of the former and 25 per cent. of the latter. It is believed by the authors that the reversible change is partly conditioned by the greater stability at this temperature of a complex compound consisting of three molecules of thiocyanate and one molecule of thiourea.

The first number of vol. i. of the *Biochemisches Centralblatt* has just been published. In twenty-eight pages it gives abstracts of some sixty papers dealing with subjects which belong essentially to the borderland of chemistry and medicine. It is pleasing to note that a considerable number of these are auto-abstracts, for this method of summarising is the only one which ensures that the really essential points in the various investigations are brought forward. The issue also contains a short summary by N. Zuntz of the recent work which has been carried out in America on such an elaborate scale by Atwater and his co-workers on the metabolism of the animal body. To physiological chemists, the *Centralblatt* will no doubt prove of considerable value, serving, as it is intended to do, for the collection of reports on all published medico-chemical investigations.

The much-discussed question of the relationship between the red and yellow oxides of mercury may now be regarded as definitely decided. The experiments which lead to this conclusion form the subject of a paper by K. Schick, published in the last number of the *Zeitschrift für physikalische Chemie*. The results indicate that Ostwald's view that the difference between the two oxides is merely due to a difference in the size of the particles is the correct one, and that the older hypothesis, according to which the oxides are isomeric, is no longer tenable. Determinations of the solubility of the pure oxides in pure water at 25° C. show that they have practically the same solubility. Of the yellow oxide, one part dissolves in 19,300 parts of water, and one part of the red oxide in 19,500 parts. Such a small difference is due, in all probability, to the difference in the size of the grains.

The current number of the *Zeitschrift für physikalische Chemie* contains an interesting paper by Dr. M. Wildermann on chemical dynamics and statics under the influence of light. The author's object has been to ascertain, if possible, the law which regulate the velocity of chemical change and the condition of chemical equilibrium, when such change is conditioned by the introduction of light energy into the system. In other words, it was proposed to investigate whether the velocity is proportional to the amount of light absorbed in unit time independent of the concentrations of the reacting bodies. The special chemical change which has been studied is the union of carbon monoxide and chlorine, a reaction which takes place only under the influence of light. A theoretical discussion of the experimental results leads the author to conclude that the velocity of a chemical reaction which is brought about (or influenced) by

the introduction of light energy follows the same law in the light as in the dark. In the latter circumstances, the only active forces are those of chemical affinity. The influence of the light energy is therefore quite different in its effect upon the reacting substances from that of electrical energy, the effect of the latter being regulated, of course, by Faraday's law.

THE additions to the Zoological Society's Gardens during the past week include a Bennett's Wallaby (*Macropus bennetti*) from Tasmania, presented by Lady Boord; a Spotted Salamander (*Salamandra maculosa*) from Italy, presented by Mr. G. Bottini; two Bennett's Wallabys (*Macropus bennetti*) from Tasmania, a White-fronted Amazon (*Chrysotis albifrons*) from Cuba, three Ring-necked Parrakeets (*Palaeornis torquatus*, var.), a Gangetic Trionyx (*Trionyx gangeticus*) from India, a Ruff (*Machetes pugnax*), a Skylark (*Alauda arvensis albino*) British, a Himalayan Monaul (*Lophophorus impeyanus*) from the Himalayas, deposited.

OUR ASTRONOMICAL COLUMN.

NEW VARIABLE STAR 21, 1902, SAGITTÆ.—From photographs taken by M. S. Blakjo at Moscow, Madame Ceraski has found that the star having the position

$$1855\ \alpha = 20\text{h. }13\text{m. }47\text{s.},\ \delta = +20^\circ\ 39'\cdot0,$$
$$1900\ \alpha = 20\text{h. }15\text{m. }46\text{s.},\ \delta = +20^\circ\ 47'\cdot3,$$

is a variable.

The magnitude varies from 9·5 to 11·5 or a little more, and M. Blakjo believes the period to be a long one, perhaps several weeks or months. In September, the actual visual magnitude was 11·5 (*Astronomische Nachrichten*, No. 3836.)

"THE HEAVENS AT A GLANCE," 1903.—The seventh yearly publication of this handy card is full of useful astronomical information for amateur observers. In addition to the usual monthly "Celestial Diary," tables of "Sidereal Objects" and "Descriptive Notes," it contains two small star charts which will be found very useful. The card may be obtained from its compiler, Mr. Arthur Mee, Llanishen, Cardiff, price sevenpence, post free.

OBSERVATIONS OF LONG-PERIOD VARIABLE STARS.—In Nos. 3835-6 of the *Astronomische Nachrichten*, Father Esch, S.J., of Valkenberg, gives the detailed results of his observations of seventy-eight long period variables. The objects are denoted by their names and numbers in Hagen's "Atlas Stellarum Variabilium," and the dates of their maxima, with the amount of variation from the elements given in the Atlas, are given, together with their range of variability and remarks by the observer.

OBSERVATIONS OF OCCULTATIONS.—Mr. G. W. Hough, director of the Dearborn Observatory, gives the details of his observations of ninety-one occultations of stars by the moon, during the years 1900 and 1901, in No. 528 of the *Astronomical Journal*.

He divides the phenomena into four classes, and in the fourth class he places those in which the star appears to be projected on the earth-like disc of the moon for some seconds before the final disappearance; he explains this phenomenon by suggesting that, as the edge of the moon is not a smooth outline, the star may pass behind the moon at a point where there is a depression in the limb and so appear to be projected beyond the geometrical outline of that limb.

In the case of the occultation of the star D.M. + 20° 807 on February 25, 1901, the star apparently disappeared and the time was recorded, but it was seen again and a second record made 3·8 seconds after the first. This phenomenon was undoubtedly due to the reduction in light of a close double when the one component had passed behind the limb, for the object was afterwards identified as Ho 332, $p = 125^\circ\cdot9$, $s = 1''\cdot03$, 9m.–9m.

The phenomenon observed on the occultation of the star S D.M. – 20° 4810, on October 17, 1901 ($p = 106^\circ$), belonged to the fourth class mentioned above, for the star appeared to be projected on the limb of the moon two or three seconds before its disappearance.

THE VACCINATION ACTS.

THE present position of the law relating to vaccination in England is indefensible. There is probably no great question in the domain of medicine on which the medical profession are nearer to absolute unanimity than that of the value and necessity of vaccination as a protection against small-pox. Independently of professional authority, perhaps no medical doctrine has for its basis so great an amount of statistical evidence gathered over so wide an area for so long a time. This unanimity of belief and this statistical evidence are equally strong and of equal value as regards the primary vaccination of infants and the revaccination of adolescents.

It is not the purpose of this paper to cite any of the evidence in question. What the writer desires to point out here is that the existence in this country of Acts of Parliament making vaccination of children obligatory, or even providing expensive administrative machinery for the vaccination of persons voluntarily asking for it, must be taken as proof that Parliament accepts the conclusion that vaccination prevents small-pox. But the legislature is in the strange position of insisting on infantile primary vaccination and of making no requirement whatever regarding revaccination. At one time, and indeed up to a comparatively recent date, this attitude was defensible, for the great mistake of Jenner's life was that he believed a single vaccination to be sufficient for permanent protection, and the veneration naturally entertained for his name and work probably delayed general recognition of the need for repetition of the operation. That need, however, has now long been recognised, and the experience of Germany shows that vaccination in infancy and a single revaccination at a proper interval afterwards are sufficient to confer national protection against small-pox, though no doubt in any such protected nation or empire there will be individuals who owe their freedom from small-pox more to their being surrounded by a vaccinated and revaccinated population not liable to epidemics than to the permanence of their own personal immunity. No argument can be used in favour of a law of primary vaccination which is not also valid for a law of revaccination. If there is any reason for having no Revaccination Act, the same reason exists for having no Vaccination Act at all. Both should stand or fall together.

The importance of a Revaccination Act for England was prominently but unsuccessfully brought before Parliament when the law was being altered in 1898 by the passing of the temporary Act which came into force at the end of that year. The main features of that measure were the provision of domiciliary vaccination and the much-debated Conscience Clause. The Act was passed experimentally only for a period of five years, and comes to an end on December 31, 1903. Next session is practically certain to see one of two alternatives adopted by Government. Either new legislation will be introduced or the Act of 1898 will find a place in the Expiring Laws Continuance Bill. This latter course would shelve several questions which cry out for solution and ought not to be shelved. To prevent its adoption and to help Government to frame any new measure on the best lines are among the principal reasons for the formation of the Imperial Vaccination League, the first meeting of which was held in London lately under the chairmanship of the Duke of Northumberland. The League has other important objects before it. It desires to educate and interest the public generally in the subject of vaccination and revaccination. As concerns legislation, it has under consideration by separate subcommittees the questions of a Revaccination Bill, the supply of lymph prepared by Government or under Government supervision for the needs of the whole country, and the question of the proper local authority for the administration of the Vaccination Acts. The last of these, though an important administrative subject, is after all of much less public moment than the two others—the protection of the lymph supply and obligatory revaccination.

The risks attached to arm-to-arm vaccination in this country were greatly overstated by anti-vaccinationists. In no class of the population was arm-to-arm vaccination more uniformly resorted to than in the families of medical men, and the Royal Commission, which sat for the long period of seven years, concluded, after elaborate inquiry, that the risks were insignificant and were diminishing. Nevertheless, they recognised that the fear of injury from vaccination and especially the fear of syphilitic inoculation was a potent factor in hindering people from securing the protection of their children against small-pox.

Quite independently of such fears—and this also, of course, the Commission pointed out—it is the obvious duty of the State to take every practicable precaution to prevent harm to the individual through the operation of any Act of Parliament. This applies alike to vaccination and to hospital isolation. If, for the public good, a child is removed from the parental roof to a public hospital, the authority so removing it, and coming temporarily *in loco parentis*, is bound to exercise the utmost care in the protection of the child. Though vaccination differs from hospital isolation in respect that it is done directly for the benefit of the child and only indirectly for the good of the public, yet the obligation remains. Every risk, no matter how slight, should be minimised by every practicable and reasonably available means before the State compels the parent to procure the vaccination of his child. The demand, therefore, that Government shall itself supply for every required vaccination calf lymph treated according to the best known methods—methods which have been much improved since the Commission issued its Report—or shall efficiently supervise the manufacture of lymph by private makers, is a most reasonable one, and has the support alike of lay and medical opinion.

It is necessary to consider how this can be done. Here, as in every other mundane affair, questions of finance and economy arise. Before the Act of 1898 came into force, public vaccinators appointed by boards of guardians performed about half of the primary vaccinations done in London and about two-thirds of those done in the provinces. How the figures now stand I do not know, but at present all that Government undertakes with regard to lymph supply is to meet the requirements of public vaccinators. Private practitioners must find their own lymph. This, at first sight, seems a harsh and arbitrary rule, but it may be assumed that the Local Government Board has some ground for its attitude. The facts of the case furnish the explanation. For due removal of extraneous organisms, calf lymph has to be stored for one month in the glycerine with which it is mixed. If lymph be used too soon, insufficient removal of such organisms may result occasionally in an unnecessary degree of inflammation accompanying the formation of the vaccine vesicles. If stored too long, on the other hand, the lymph may become inert for purposes of vaccination. At present there is great irregularity of demand for vaccine lymph in England, depending on the absence of systematic revaccination and the occurrence of epidemics of small pox. If under present conditions the Local Government Board must always be ready to provide sufficient lymph to every medical man who asks for it for vaccination and revaccination during small-pox epidemics, a great establishment will have to be set up, producing month by month such amounts of lymph as may not be wanted at any time for ten or twenty years on end, and month by month this huge excess of valuable material will have to be thrown away. Merely to set forth such a scheme is to condemn it. How, then, is the object to be accomplished? The answer is, only in one way, and that way a Revaccination Act. Under such an Act, revaccination would be obligatory at about the age of twelve years. The information necessary for working the Act would be most readily obtained from the registers of the elementary schools. The vaccination officials would be furnished at frequent intervals, say every three months, with lists of children about to attain the specified age. Primary vaccination would, of course, remain obligatory as at present. Both revaccination and primary vaccination, it may be assumed, would be subject to a Conscience Clause, though the present Clause is open to considerable amendment. The work of vaccination would go steadily on. The Government laboratories would be on a scale suited to meet the requirements of the nation, and the public funds would not be squandered in maintaining an institution the full work of which would be utilised only at rare intervals. Outbreaks of small-pox would be few and local and limited in degree, and the laboratories would easily meet demands for lymph for revaccination of "contacts" and others on such occasions.

Another great advantage from systematic revaccination would be an enormous saving in the provision and maintenance of small-pox hospitals. At present, local authorities are, with regard to this matter, in a most exasperating position, and that through no fault of their own. The Local Government Board insists that, owing to an evil which has often resulted from such hospitals—the spreading of small-pox throughout the surrounding community—these institutions for the isolation of patients shall themselves be isolated. Small-pox is a disease for which hospitals are almost entirely unnecessary in a duly vaccinated and revaccinated community, yet local authorities have no power to enforce such protection of their community, and when they set about trying to provide hospitals, they experience the utmost difficulty in obtaining safe sites. Other economies would result from the scheme here briefly sketched, but the above are the main reasons for asking Government to introduce a Revaccination Bill, and are also among the main reasons for the formation of the Imperial Vaccination League. Already the Jenner Society has done most admirable work in the same field, and both are well worthy of public support, especially at so critical a time in the history of legislation for the prevention of small-pox.

In criticism of the plea for a Revaccination Act as here put forward, it may perhaps be urged that the acceptance without demur of a Conscience Clause with regard even to primary vaccination is hardly consistent with a demand for a law of revaccination. What would be the sense, it may be asked, of establishing all the additional machinery which a Revaccination Act would involve for the protection of the public against small-pox and at the same time telling the public that if they please they can evade both primary vaccination and revaccination by satisfying a bench of magistrates that they have a "conscientious" objection on the subject? The force of such a contention is not to be denied. Admittedly, the Conscience Clause is a concession to expediency. For justification of such a concession, we must go to the facts of the position. In the first place, it is important to note that the Royal Commission on Vaccination suggested a Conscience Clause with the object, not of lessening the practice of vaccination, but of increasing it. In the second place, even before the Conscience Clause was passed, vaccination was not in any real sense of the word compulsory. In order to evade the operation, it was only necessary to pay a fine, either once or repeatedly, according to the activity or otherwise of the local guardians. The law never allowed a local authority to take a child by force out of a parent's arms and vaccinate it. Exemption, therefore, though not by way of certificate, was always possible. Laws must be framed and administered with due regard to the spirit of legislation which prevails in the country. If it so pleases, Parliament has a right to adopt the attitude that, bad as are small-pox epidemics, they are a lesser evil than would be the exercise of absolute force in such a matter as the insertion of vaccine lymph into the arm of a child notwithstanding the determined opposition of the father. The fining of persistent and active anti-vaccinationists, the public sale of their goods in default of payment of such fines, or the imprisonment of objectors where payment of fines could not in this way be obtained, have been in the past measures most favourable to agitation against vaccination. The purpose of the Conscience Clause in the Act of 1898 was to sift the genuine and confirmed opponent of vaccination from the merely careless and indifferent parent who had no opinion on the subject, but would leave the matter alone so long as he himself were left alone, and would, on the other hand, have his child vaccinated if he found that that would cause him less trouble than to take the steps required to obtain exemption from the law. On the whole, the Conscience Clause of 1898 has probably promoted vaccination rather than hindered it. Yet in practice the clause has proved itself defective in two directions. Its administration has been left to benches of local magistrates, and their views vary much as to the proceedings which should be taken. In one place, an anti-vaccination bench may hold evening sederunts where long strings of alleged "conscientious objectors" pass rapidly in front of the bench and are detained only so long as is needed for adhibiting magisterial signatures to exemption certificates. At such gatherings, either fathers or mothers may attend. On the other hand, other benches of magistrates may refuse almost any evidence submitted to them on the ground that it does not "satisfy" them that conscientious objection exists, and in Parliament it has been stated, in answer to questions on the subject, that there is no power under the Clause to compel a magistrate to be "satisfied" with any amount of proof. A parent whose certificate is refused in such a court may afterwards be brought before it for having failed both to have his child vaccinated and to produce an exemption certificate. Obviously, the present Conscience Clause allows too much variety of practice and requires a substitute less open to these objections, a substitute which, if possible, should so detail the proceedings to be taken that, on the one hand, they would involve at least as much parental trouble as the procuring of vaccination would cause, and, on the other hand, would not

needlessly pester nor afford the notoriety of cheap martyrdom to any man sufficiently wrong-headed to be quite determined to resist the vaccinal protection of his child.
